LABORATORY AIDS IN CLINICAL DIAGNOSIS.

C. E. RUTH, M.D.
Professor of Descriptive and Surgical Anatomy and Clinical Surgery, Keokuk Medical College, College of Physicians and Surgeons,
AND
A. S. RIDER, M.D.
Instructor in Pathology, Keokuk Medical College, College of Physicians and Surgeons.
KEOKUK, IOWA.

A diagnosis may be anatomic, clinical or etiologic. By anatomic diagnosis is meant a description of the tissue changes that have taken place in the body as a result of disease, based on a study of the dead body. By clinical diagnosis is meant an opinion as to the nature, cause, probable course and termination of a pathologic process, based on a study of the living body. By etiologic diagnosis is meant the identification of the specific cause of a given pathologic process in an individual case. To illustrate: By means of the physical signs and a study of symptoms, the physician establishes the clinical diagnosis of lobar pneumonia. The exudate from the lungs is examined and the pneumococcus and staphylococcus are found, which establishes the etiologic diagnosis.

The patient dies, and at necropsy a study of the gross and microscopic changes in the lungs is made, which comprises the anatomic diagnosis. The anatomic and etiologic diagnoses are exact and definite. The clinical diagnosis should be as exact as the available means can make it.

It is obvious that an exact knowledge of the anatomic changes and the causative agencies is of great importance, because of its influence on therapeutics. A diphtheritic process due to the streptococcus can not be expected to yield to a Klebs-Loeffler bacillus antitoxin. Antistreptococcus serum can not and will not modify a septic process due to the colon bacillus or staphylococcus. Before we heroically assail our patient or perhaps our victim with enormous doses of quinin, it is well to be positive of the existence of his malaria.

The trend of medical research is along the line of pathology, and rightly so. The clinician, however, has followed closely in the wake of the pathologist, and as he establishes definite causative agents, anatomic peculiarities or physiologic variations in certain diseases, the clinician has eagerly seized on his methods whenever he could make them available for use on the living patient. The pathologist, Koch, demonstrated the tubercle bacillus to be the cause of tuberculosis. The clinician hunts assiduously for that bacterium in the sputum to establish definitely his diagnosis of phthisis. The curious phenomena of the cytolytic and agglutinative action of different sera on the specific bacteria, to whose activity they have become relatively immune, was no sooner announced than the law was applied to the diagnosis of typhoid fever as the familiar Widal reaction. The pathologist noticed that in certain diseases a large increase in the circulating leucocytes occurred. The clinician found the estimation of the degree of leucocytosis to be a most valuable means of differential diagnosis and of considerable prognostic import.

In this way the researches of workers in the laboratory and the dead house have not only increased and made more exact our understanding of the diseases we are called on to combat, but they have incidentally greatly facilitated their recognition and made it more often possible for the diagnosis to be an exact one. It is not needful to emphasize the importance of care and exactness in diagnosis. The lay mind as well as the medical is fully alive to its fundamental value.

We have said that the trend of modern workers is along the lines of pathology and diagnosis, and on the surface it would seem that therapeutics is being forgotten. It is a fact that we are, to a considerable extent at least, abandoning our store of empiric drug therapeutics and are losing faith in many of our vaunted pharmaceutic specifics. One familiar with the structure of the calculi abnormally found in the biliary or urinary bladder, looks with skeptical eyes on the phosphates, olive oil, oleic acid, lithia, etc., that are offered him as potent solvents. The surgeon familiar with the dense structure of a uterine fibroid has rightly doubted the adequacy of ergot to cause its atrophy.

When the assertion is made that by a certain favorite intestinal antiseptic, a physician has been able to abort the disease or to shorten its duration in his typhoid cases, we must confess a doubt that his minute doses of calomel, carbolic acid, etc., are potent to exert an appreciable influence over twenty feet of intestine and the entire blood stream. In 80 per cent. of cases it is possible to isolate the typhoid bacillus from the blood, and typhoid is more often a general typhoidal bacteriemia than an intestinal disorder.

We should not become drug nihilists or approve of the do-nothing policy which so many disappointed drug users have adopted, but certainly greater care is needed in ascribing to drugs good effects that are due either to the effect of a careful hygiene or to other agencies, always remembering Nature's kindly aid and not failing to give her full credit at all times. However, the pathologist has not undermined our symptomatic drug therapeutics without giving us full compensation.

As we were formerly inexact in our understanding of pathology, we could not be otherwise than inexact in treatment. With exactness in our knowledge of pathology and with the possibility of exact diagnosis on the living patient, has come the vanguard of the era of precise and specific therapeutics. Antitoxin, anti-streptococcic serum, antitetanic serum and vaccination immunity are beyond the stages of experiment in their effects, and their failures are largely to be attributed to inaccuracy in their use.

With the advent of specific therapeutics—with its promise of a brilliant future—comes a still greater need for exactness in our clinical diagnosis. The ideal clinical diagnosis should reveal all the information that the etiologic and anatomic diagnosis comprises. The laboratory has brought many means of precision to the clinician, and we will briefly note some of the more important ones.

In typhoid fever, malarial infections, many forms of tuberculosis, gonorrheal inflammations, cerebrospinal-meningitis, pneumonia, septicemia, chlorosis, severe secondary anemias, actinomycosis, amebic dysentery, different forms of intestinal parasitic infections, intestinal, uterine and gastric cancer, true diabetes, certain forms of endometritis, anthrax, echinococcus infections, filariasis and some other conditions, the laboratory frequently affords the means of an exact diagnosis. In many of these diseases, diagnosis is impossible without laboratory aid, and in all of them it offers final and definite testimony. In many more conditions laboratory investigations offer to the physician valuable information, additional to that he has already gained, and is most helpful in differential diagnosis.

As diagnostic aids in typhoid fever, we have the Widal reaction, and more recently the bacteriologic examination of the blood. Cabot reports positive Widal reactions in 95 per cent. of 3,000 cases of clinical typhoid, and of 2,500 control cases only 2 per cent. reacted. In a case difficult of diagnosis, a positive reaction is, therefore, almost a positive evidence of typhoidal infection. Most important, however, is the bacteriologic examination of the blood. Eberth's bacilli can be found in from 80 to 90 per cent. of the cases. They are most frequently found from the second to the fifth day of the disease. The technic is not difficult, but demands great care. Bacteriologic examination of the blood affords an exact diagnosis at an early date. As negative evidence, it is not as yet to be relied on. The skin of the forearm is sterilized, a vein rendered prominent, and by means of a sterile aspirator needle, blood is withdrawn and inoculated into a tube of blood serum or agar, and after from twenty-four to forty-eight hours in an incubator, the bacillus is identified by its morphologic and cultural peculiarities. The use of plate cultures is to be recommended as an aid in the identification of the colonies and as an additional safeguard against contamination of the cultures.

Malaria has long been a scapegoat for certain members of the profession. The diagnosis of a "touch of malaria" has often taken the place of an explanation of a patient's real or fancied illness. Malaria is a parasitic disease of the blood, and to establish its diagnosis it is needful to identify the parasite in the blood. A careful search will almost always reveal its presence. A negative finding, after a careful search, is of considerable negative value.

In pulmonary tuberculosis, the finding of the tubercle bacillus in the sputum is of the greatest diagnostic import, and their constant absence, after many examinations, is of considerable negative value, though not a final test. The presence of elastic fibers speaks positively for disintegration of lung tissue. In tuberculosis of the bladder or kidneys, the diagnosis is often cleared up by finding the bacilli in the urine, though here a negative finding is of no value whatever. Inoculation of a susceptible animal and a subsequent study of the experimental disease may be of great value where more direct methods have failed to reveal the nature of the infection.

It is possible to differentiate a gonorrheal from a pus microbe inflammation by examination of a smear preparation of the exudate, though here a negative result is of small value, except during the early stage of the disease.

In cerebrospinal meningitis an examination of the exudate obtained by lumbar puncture may reveal whether the symptom complex is due to the tubercle bacillus, pneumococcus or *Diplococcus intracellularis meningitides*. A pneumococcus meningitis is always fatal. A tubercular meningitis is uniformly fatal. The epidemic form due to the *Diplococcus intracellularis* may recover. The value of these findings is obvious.

In lobar pneumonia the pneumococcus is easily demonstrated in the sputum. It can, however, be found in 20 per cent. of normal individuals, which lessens the value of the finding.

In ulcerative endocarditis and septicemia, a bacteriologic examination of the blood may often reveal the identity of the infecting agent which may give a hint in treatment or at least serve to clear up a cloudy diagnosis.

A granule from a submaxillary abscess crushed under a cover glass may show the presence of the ray fungus and establish the diagnosis of an actinomycotic infection.

By examination of the stomach contents, definite data can be obtained as to the presence or absence of hydrochloric acid, pepsin, rennen, lactic or other organic acids, and when present the percentages may be determined. The rapidity of digestion may be estimated, and tumor particles, pus, blood, bacteria, etc., detected if present.

By examination of the stools, the *Ameba coli* may be found in amebic dysentery, tumor particles in intestinal cancer, pus, blood, and perhaps the tubercle bacillus in ulcerative processes in the bowel.

The specific gravity, reaction, albumin and sugar determinations are but the rudiments of urinalysis. The microscope is essential for a proper study of the urine. A careful study of the epithelia, different varieties of casts, and noting the presence or absence of bacteria, pus, and blood is absolutely essential in order to obtain anything like a definite idea as to the condition of the urinary apparatus. Even then it must be confessed that it is at all times difficult and often impossible to determine by urinalysis the anatomic changes in the kidneys with which the clinician will be confronted at the autopsy. Is there pus or blood present? If present, is it from the bladder or kidney? Is the renal parenchyma affected? Is the process tubercular or due to the colon bacillus or pus cocci? These are some of the questions that a proper study of the urine will answer, often with exactness.

During the last five or six years much attention has been given to the examination of the blood, and no field of medical research is more promising for investigation. Much has already been done, but much more still remains to be done. There are many reasons why the examination of the blood is of great interest to the clinician. First, it is the only tissue of the body that is at

all times readily available for study in the living patient. Second, from its physiologic position in the body, it must of necessity reflect in some way every variation from the normal that may take place in the organism, whether it be a general or a local variation. It is plain of what vast value it would be if we possessed definite information as to what these changes are and under what circumstances they occur. Thus far our studies of the blood have been chiefly in morphology. It is to the chemistry of the blood that we must look for the greatest aids in diagnosis in the future, but at the present, blood chemistry is practically an unexplored field. In five or six diseases, a diagnosis rests entirely on the blood examination. In every febrile disease, an examination of the blood will offer some light. In malaria, leukemia, filariasis, pernicious anemia, relapsing fever and chlorosis, exact diagnosis is impossible without a blood examination. However, the most generally valuable finding is the presence and extent of any leucocytosis. Every febrile process has a leucocytosis, with the following important exceptions: Malaria, typhoid fever, pure tubercular infections, measles, and the early stages of la grippe.

Leucocytosis is most pronounced in lobar pneumonia and suppurative diseases. Its presence or absence in a given case is of great diagnostic aid in placing a febrile disease in or out of the above list. A diagnosis of anemia should be based on the estimation of the percentage of hemoglobin and the number of red cells present. Any other method allows of a wide range of error.

We have endeavored to briefly outline a few of the more important aids in diagnosis afforded by the laboratory. No effort has been made to detail technic, as our space is too limited. In spite of the generally recognized great value of technical diagnostic aids, they are not employed by the average practitioner, and to any extent by very few indeed outside of the larger hospitals. Several factors go to account for this: First, to equip a laboratory requires considerable expense; second, many physicians have not the technical training and lack the time to acquire it; third, some because of a lack of diversity in their available material, do not have an opportunity to become proficient. In other words, the average physician is too busy, thinks it won't pay or lacks the taste or opportunity to become skilled in technic.

The solution of the problem lies in co-operation. With an expenditure of $10 and an arrangement with a laboratory within twenty-four hours' ride, any physician can have laboratory advantages at his disposal. All that is needed is a few glass slides, some culture tubes, platinum needle, alcohol lamp, Thoma-Zeiss white cell pipette, Tallqvist hemoglobinometer and a book on technic to obtain and forward material for a leucocyte count, hemoglobin estimation, bacteriologic examination of blood, urine, exudate or whatever else may be desired. One member of the community of physicians can go to the expense of fitting a laboratory and becoming proficient in technic. His neighbors can either share the expense and go there to make their examinations, or what is better perhaps for both, have one who has the time and taste, do the work for all. Practice makes perfect, and better observations would be secured by such a plan. A mutual agreement should be made as to the sharing of expense, and by a very small personal outlay a town possessing a faculty of only six or more physicians could have a sufficiently well-equipped laboratory and afford enough work to enable one or more of their number to become reasonably expert. We have not the time to elaborate this plan, but simply wish to state how, by means of harmony and mutual aid, it would be possible to bring the means of diagnostic precision within the reach of practically all the profession.

In many of the larger cities municipal laboratories have been established and have done much good work, especially in dealing with the epidemic and contagious diseases. Being municipal laboratories only, they reach but a small proportion of the profession. It is not unlikely, in view of the good work done by the city laboratories, that the state will eventually place at the disposal of the general profession an adequate number of well-equipped laboratories that would not only offer technical aid in general diagnosis, but would require that their services be employed in all cases that might have a bearing on the health of the general public. It must of necessity be some time before any generally efficient state aid can be expected, and meanwhile the profession must rely on their own efforts to obtain laboratory aid in diagnosis.

A CASE OF CIRCULAR INSANITY STUDIED FROM CLINICAL, DIFFERENTIAL AND FORENSIC STANDPOINTS.*

RICHARD DEWEY, A.M., M.D.
WAUWATOSA, WIS.

WITH GROSS AND MICROSCOPIC ANATOMY OF BRAIN (FROM THE PATHOLOGICAL DEPARTMENT OF THE UNIVERSITY OF CHICAGO), BY THOR ROTHSTEIN, M.D., CHICAGO.

(*Concluded from p. 1133.*)

FIFTH MANIC-DEPRESSIVE CYCLE.

In October, 1895, a petition *de lunatico* was again filed, and at the hearing it was testified that he had shown an immoral photograph to a young girl of twelve. This hearing was interrupted by a scuffle and altercation in court between X. and a witness, and by his calling the judge a "cheap skate." He was committed to jail for contempt. Immediately after he made three applications for a habeas corpus before as many judges, two of which were denied. He was released on the third and immediately rearrested, and when later the hearing on the question of insanity came up before a jury, the latter brought in a verdict of sanity, and he was never declared insane or committed to an institution for the insane again; not because he did not continue to exhibit an unbalanced mind, but apparently because all attempts to control him were given up in despair. From this date I have no detailed knowledge of the periods or phases of exaltation and depression. They continued to recur in an irregular manner. X. had in September, 1893, been restored to his property rights and his conservator had been removed by the probate court. His property was at that time estimated to amount to $45,000, and was eventually dissipated by him so that at his death, seven or eight years later, I understand little or nothing was left.

In November, 1898, he was arraigned before a justice on charge of assault with deadly weapon, could not secure bail and was sent to jail. Later he appeared in circuit court, poured a pitcher of ice water over his head, rubbed it with a newspaper in lieu of towel, and then asked for a *certiorari* on the justice who had committed him.

In January, 1897, he started in the superior court 16 suits for personal damages aggregating $1,464,000. At this time two of his children filed affidavits desiring to stay with their mother.

During the years from 1893 to 1898 much of the time he occupied his residence on one of the handsome boulevards. He would sit at his door and anyone passing by in the street was liable to be made the subject of some practical joke. He would array himself at times in kilts and in dress and conduct was absurd and eccentric in the extreme. Often nonsensical signs and notices were hung in his windows, and the interior of the house was a scene of disorder and confusion indescribable.

SURGICAL INTERFERENCE.

In 1898 he consulted me about an operation on his brain, stating that Dr. J. B. Murphy had agreed to operate if I would recommend it. His claim was that the injury to his head in 1889 was the cause of his insanity. I stated to him that I could not recommend the operation, because his insanity undoubtedly antedated the injury, because there were no focal symptoms, motor or sensory, pointing to any certain region of the brain as the seat of disease, nor were there local evidences of injury to the cranium sufficient to justify an operation. I informed him finally that a physician who had seen him immediately after the injury had informed me he presented no signs at the time of concussion or compression. X. stated that granting all that to be true, still he was determined to have the operation, if for no other reason than for its effect on the public. He felt he had lost to a great degree the confidence of the public, and, if he could announce that the disorder of the brain caused by the injury to the head had now been removed by operation, he would regain the standing he had lost and could again get back his formerly lucrative law practice. The operation of trephining was done in October, 1898, I learned from the newspapers. The particulars of the operation have not, so far as I know, been reported. Evidence is lacking, however, in the subsequent history of the case to show *material* change in the patient's condition either for better or worse. Before submitting to the operation X. made his will—a characteristic document, in which he directs that his funeral be held in the West Side High School, of which he considered himself the "father and partial designer." He names for honorary pallbearers several of the first citizens of Chicago, beginning with Mayor Harrison. Some of these men had been his friends in years gone by. He gave his cranium to one physician, the rest of his skeleton to another and his heart to a third. He directed that models should be made of his skull and given to the medical colleges of Chicago, also to about twenty physicians in New York and Chicago; also that a death mask should be made and cast in bronze and presented to his friends, etc. This will, though eccentric, seems inconsistent with the theory of paresis having existed nine years.

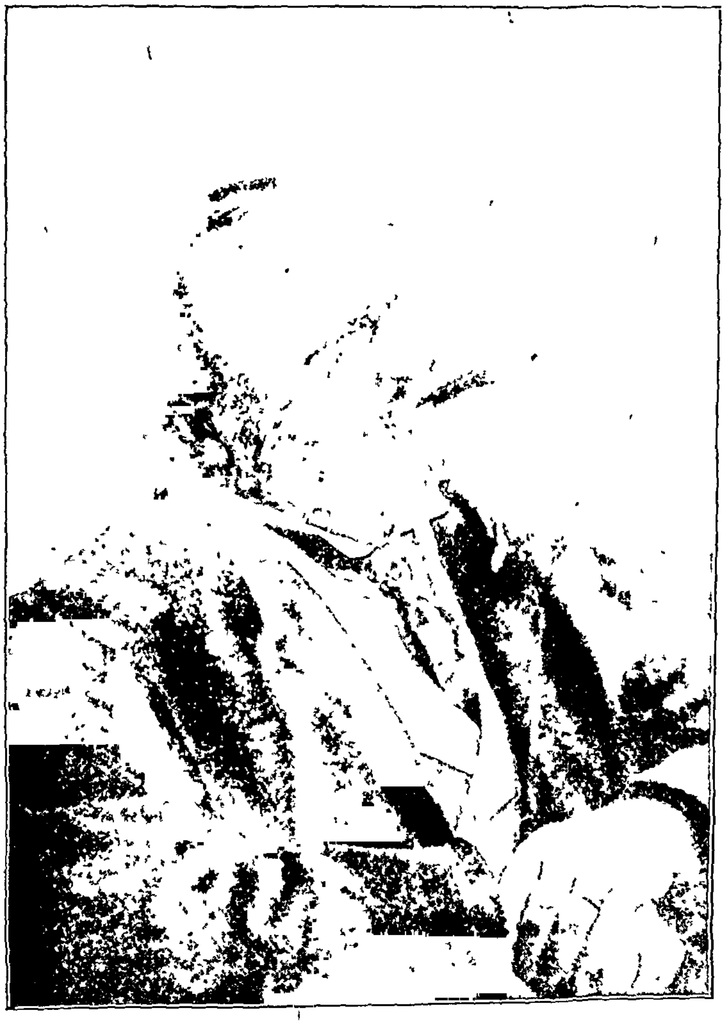

Fig. 4.—Deterioration. Obesity, aged about 40

ASYLUM DELIVERIES.

In the fall of 1898 and the following winter and spring the patient spent some time in Elgin, Ill., led thither, as he stated, by an "affair of the heart." (He had previously been divorced.) During this time he came in contact with patients in the state hospital who claimed they were wrongully confined, and he secured the legal release of three such patients on habeas corpus; he also brought suit in three other cases and obtained the discharge of a girl from the State Home for Juvenile Offenders at Geneva. His "affair of the heart" did not run smoothly. A paragraph in the press in April, 1899, told of his engagement being severed at Moline, Ill. After he had lost sight of his fiancée for some time he sought her in three different states and spent "$86 in trying to trace her by telephone." He implored her to accept him at the police station in the presence of patrolmen and reporters. She remained obdurate and later returned his presents.

In November, 1900, X. secured the release from the Hospital for the Insane at Kankakee of an undoubtedly insane patient, and began suit against the authorities for $250,000 for illegal detention.

In February, 1901, the patient successfully defended a patient in an insanity inquest in Milwaukee. This patient, too, was palpably and undoubtedly insane.

In August, 1901, the death of X. occurred at the Cook County Hospital from typhoid fever. It was stated in the press at the time that an autopsy was held by Dr. E. P. Noel. The brain was placed in possession of Dr. Ludvig Hektoen, who gave it for examination to his associate in the laboratory of Rush Medical College, Dr. T. Rothstein, who will submit his findings at the close of this paper.

DIFFERENTIAL DIAGNOSIS.

From such knowledge as I had, I arrived at the diagnosis of circular insanity, and here offer a few words on the *differential* diagnosis.

In reviewing this case from the standpoint of diagnosis, it may be stated that circular insanity is unmistakably shown by the clinical history. Circular insanity is a psychosis, the essential characteristic of which is the occurrence of alternating periods of mental exaltation and depression, or manic-depressive cycles, with periods of lucidity or normal condition between. Some writers insist on a normal interval between each of the exalted and depressed phases; some between the cycles only, and find one phase passing almost immediately into the other, but the classical *folie circulaire,* as first described by Falret and Baillarger (also called *folie a double forme* and cyclo-thymia), consisted of exaltation, depression and sanity in regular succession. The only question that can arise in diagnosis of this case is whether the various cycles were or could be merely phases associated with paresis, since that disease is sometimes marked with alternating or circular mental symptoms, and since the expansive or grandiose phase of X.'s psychosis was suggestive to many minds of paresis, general paralysis or paralytic dementia, as the disease is denominated by different writers, but which I will here call general paralysis.

It is, of course, possible to refine endlessly on the points of diagnosis and to emphasize the exceptions to almost any rule, but it can be truly said, if this case was one of circular insanity, it was a typical one, and if it was a case of general paralysis, it was non-typical in the extreme. The cases of general paralysis are few indeed in which complete manic-depressive cycles occur for three or four years with strict regularity to the number of four or five; in which mental power and brilliancy are retained with accurate memory for recent and remote events, dates, etc., with logical cogency; sharp and clear power of discernment and statement and of concentration of mind and sustained attention. It is of the very essence of general paralysis that a blurring, so to speak, of perceptions and conceptions is present, even in the early stages, and the will is weak, the expansive ideas or delusions in the exalted state are fatuous and inconsistent. In the depressive state, there is more confusion and stupidity and more tendency to hypochondria, less retardation, less anxiety and discomfort—all of which considerations speak for circular insanity in the case of X. The moral deterioration in his case and the change in disposition and increased irritability might be common to either condition.

If it be granted for the sake of argument that the mental symptoms shown by this case might possibly be present in a case either of general paralysis or circular insanity, we must then look to the somatic signs for settling the diagnosis, and here, again, I find, so far as my observation went, that in the case of X. the most characteristic symptoms of general paralysis was lacking—fibrillary tremors of facial muscles and tongue, speech defects, immobile pupils, implication of cranial nerves, convulsive, spasmodic or paralytic phenomena, heightened deep reflexes—all were lacking in my observation of the case of X. It may be that colleagues who examined X. at various later periods during the twelve years of his insanity saw some of these signs, but none of them were present when I examined him. Furthermore, evidence of syphilis was lacking, which is known to be present in 75 per cent. of paretics and claimed by many the invariable cause. Again, the fact of the patient living for twelve years and dying of intercurrent disease is unusual in general paralysis, though, of course, not impossible.

The symptoms speaking for general paralysis were the grandiose ideas, which, on closer view, are, in my opinion, not characteristic, the mental and moral deterioration, which are, however, common both to general paralysis and to circular insanity. The abnormity of diminished reflexes on the left side is of neutral significance. Finally, there have been cases of general paralysis with remissions, in which great brilliancy was shown, and with a duration of ten or more years and subsidence of the symptoms, but not, so far as I know, cases in which all the symptoms were consistent with a diagnosis of circular insanity. In view of Dr. Rothstein's examination, I will not speak further of the pathologic anatomy than to say the examination of the brain fails to furnish evidence of changes such as are required to establish general paralysis.

THE PATHOLOGIC ANATOMY OF THE BRAIN.

BY DR. THOR ROTHSTEIN.

The patient died of typhoid fever at the Cook County Hospital in Chicago. From the autopsy, the brain, the part of dura covering the convexity of the brain and the middle part of the frontal bone were secured and preserved in formol and Müller's fluid. On the internal surface of the frontal bone are two groups of exostoses, one on each side of the middle line, at the point where the crista frontalis meets the sulcus frontalis. The exostoses on the left side consist of five eminences spread over a surface that is 4 cm. in length and 2.5 cm. in width. They protrude about 1-1.5 mm. The exostoses on the right side are confluent, protruding at one point 3 mm. and covering a surface 4 cm. in length and 0.5-2 cm. in width. Some parts of the dura adhere around the exostoses. The dura has the appearance as if it had been adherent to the skull, then the external layers were torn off from a considerable part of it, but the internal surface of the dura is perfectly smooth and of normal luster.

The brain, with cerebellum and medulla oblongata, weighs 1,720 gm. and hence is to be classed with the heavy brains. The pia is loosened from the brain over a small surface at the frontal pole of both hemispheres, but the underlying brain tissue is intact except that in the left hemisphere there is a horizontal cut 2-3 cm. long (made at the autopsy). There is a depression on the right hemisphere close to the fissura longitudinalis at the level of the brain corresponding to the situation of the exostoses. It is hardly noticeable on the left side, but a little more marked on the right hemisphere (Fig. 14, at the frontal pole), here measuring 1.5 cm. in height and about 0.25-0.50 cm. in depth.

The veins of the pia are distended with blood, especially over the convexity, but no thickening of the pia can be found and it is easily loosened, leaving the gyri perfectly smooth. The lateral ventricles are unusually narrow.

LEFT HEMISPHERE.

Fissura sylvii (f sy, Fig. 13) is 50 mm. long. The ramus anterior horizontalis (r h, Fig. 13) is short but deep. The sulcus designated as ra (Fig. 13) cuts down to the insula and thus must be considered as ramus ascendens anterior. It is unusually long and keeps its depth till it comes close to the sulcus frontalis medius, but the anastomosis with the last named sulcus is shallow, both sulci being separated by a deep gyrus. Fissura sylvii is bifurcated at the posterior end. The ramus posterior descendens is very short. The ramus posterior ascendens passes upward and backward, joining the sulcus intermedius (i, Fig. 13).

Sulcus centralis (c, Figs. 11 and 13)commences on the medial surface of the hemisphere and runs in a nearly straight direction forward and downward. Near its lower end it sends a branch backward and downward through gyrus centralis post to the fissura sylvii.

The sulcus cirguli (ci, Fig. 14) runs as a continuous sulcus from the genu corporis callosi to the incisura cirguli (i c, Fig. 14). In its posterior part (pars posterior—Eberstaller) it is single, but a doubling of pars intermedia and pars anterior (Eberstaller) (p a and p i, Fig. 14) exists. Orbitally from the sulcus cirguli a sulcus rostralis (s r, Fig. 14) is seen, which reaches the edge of the hemisphere anteriorly. Below a short sulcus rostralis inferior (Retzius) (s r i, Fig. 14) exists.

The sulcus frontalis superior is represented by two furrows (f s_I, f s_{II}, Figs. 11 and 12). The posterior furrow (f s_I) sends out several side branches. One passes vertically and anastomoses with sulc. frontal med. (f m, Fig. 12). The anterior furrow (f s_{11}) starts half-way between the posterior furrow and fissura longitudinalis and runs parallel to this fissure, but is far from reaching margo orbitalis.

The sulcus frontalis medius (Eberstaller) (f m_1 f m_{11}, Figs. 12 and 13) is the most prominent furrow on the frontal lobe. Its posterior portion (f m_1, Figs. 12 and 13) communicates with the sulcus præcentralis inferior (pr i, Fig. 13) and thus has replaced the sulcus frontal inferior. The anterior portion (f m_{11}, Fig. 12) sends out several side branches and ends at margo orbitalis in sulcus fronto marginalis (pars anterior—Eberstaller) (f m a, Fig. 12). Side branches from sulcus frontal med. form pars media and pars lateralis (Eberstaller) of sulcus fronto marginalis (f m a_{11} f m a_{111}, Fig. 12). Sulcus frontal inferior (f i, Fig. 13) is short and commences in front of ramus ascendens fissura sylvii (r a), from which it is separated only by a very narrow gyrus. After a short course forward it turns downward and ends in a short horizontal sulcus (f m a) a little in front of ramus horizontal foss sylv.

Sulcus præcentralis inferior (pr i, Fig. 13) is short, with a nearly straight vertical course. It communicates with sulcus frontal medius and from its lower part sends a short horizontal branch in gyrus front inferior (F. III). Sulcus præcentralis superior (pr s, Figs. 11 and 13) is composed of two sagittal sulci united in their middle by a vertical sulcus. The lower sagittal sulcus passes backward to the sulcus centralis, then cuts through gyrus centralis posterior and finally joins sulcus postcentralis (p o, Figs. 11 and 13). In this way both the central gyri are divided into an inferior and a superior portion.

On the mesial surface the gyrus central anterior forms the greater part of lobulus paracentralis (P A R, Fig. 14). On the upper surface it takes an unusually straight course. Gyrus frontal superior (F_1, Fig. 12) is very narrow in its anterior portion. Gyrus frontalis medius (F_{11}) is the most prominent of the frontal gyri and is divided into one superior and one inferior gyrus.

Nearly all of gyrus frontal inferior (F_{111}, Fig. 13) is taken up by Broca's convolution (operculum intermedius—Retzius), which is of an unusually large size and has an incisure on its surface.

LOBUS PARIETALIS, LOBUS TEMPORALIS AND LOBUS OCCIPITALIS.

Sulcus postcentralis (retrocentralis) (p o, Fig. 11) exists as a well marked sulcus. Below it starts in the fissura sylvii and goes slightly curved in the form of a retroverted S upward and backward. Not far from its upper end it joins a semicircular sulcus (p s, Fig. 11) which, with its posterior end, descends on the mesial surface of the hemisphere. This sulcus may be considered a sulcus parietalis superior (Retzius).

Laterally from parietalis superior a strongly developed sulcus interparietalis (i p, Figs. 11 and 13) is found. Posteriorly it enters the occipital lobe as a sulcus interoccipitalis (i op, Fig. 12) and ends as sulcus occipitalis transversus (o t). Anteriorly sulcus interparietalis has a vertical position, which is parallel with sulcus postcentralis and ends long before it reaches fissura sylvii. From this last named fissure a sulcus subcentralis posterior (Retzius) (s c p, Fig. 13) ascends toward sulcus interparietalis, thus completing the posterior boundary of gyrus ascendens. On the mesial surface of lobus parietalis a free sulcus subparietalis (s p, Fig. 14) exists, which anastomoses with a vertical sulcus precunei (p c, Fig. 14).

The sulcus intermedius (i, Figs. 11 and 13) starts anteriorly from sulcus interparietalis, goes backward and downward, communicating with ramus ascendens fissure sylvii and with sulcus temporalis superior and turns finally upward, ending near the sulcus interparietalis.

The sulcus temporalis superior (t s, Figs. 11 and 13) in its posterior part, sends out one upward branch (t s_1, Fig. 14), anastomosing with the sulcus intermedius. Further back it divides into two sulci, one (t s_{11}, Fig. 11) passing upward and ending near sulcus interparietalis; the other passes backward, joining the ascending part of the sulcus temp. medius.

The sulcus tem. medius is subdivided in three portions (t m_1 t m_{11} t m_{111}, Fig. 13). The posterior portion anastomoses by a short, shallow sulcus with incisura preoccipitalis (pro, Fig. 13), thus forming a sulcus preoccipitalis (Wernicke), and communicates with sulcus temporalis superior and sulcus occipitalis lateralis superior.

The sulcus temporalis inferior (t i, Fig. 14) runs forward from incisura preoccipitalis and is represented by two separate sulci. A deep sagittal sulcus exists in gyrus fusiformis.

The sulcus occipito temporalis (fissura collateralis) (o t, Fig. 14) presents at its posterior end two transverse branches, the mesial of which reaches the occipital pole, the lateral ends in incisura preoccipitalis. At the point where it reaches the gyrus hippocampus it is joined by a sulcus lingualis (s l, Fig. 14).

Fissura parieto-occipitalis is typical, but anastomoses even deeply with fissura calcarina, which further on at the occipital pole, turns over on the lateral surface. Behind fissura parieto-occipitalis a sagittal sulcus cunaei extends (s c, Fig. 14) to the occipital pole.

On the lateral surface of the occipital lobe are found the sulcus occipitalis lateralis inferior (o l_2, Fig. 13) and the sulcus occipitalis lateralis superior (o l_1, Fig. 14), which anastomoses anteriorly with sulci temporalis superior and medius and sends one transverse branch which ends near sulcus interparietalis.

The gyrus centralis post (C P, Figs. 11 and 13) has a nearly straight course. It is very broad in its middle part and upward it passes into a short, thick gyrus parietalis superior medialis (p s, Fig. 11) (gyrus arcuatus ant.—Retz). A well-defined gyrus parietalis ascendens (P A, Fig. 11) that stretches backward to fissura parieto occipitalis is formed, giving the brain a three gyral type.

The gyrus supramarginalis (S M, Fig. 13) is divided by sulcus intermedius and not very well defined. Gyrus angularis (G A, Figs. 12 and 13) is well developed, but has taken the place of the gyrus parietalis inferior posterior. Lobus parietalis inferior as a whole is poor in gyri. Gyrus temporalis superior (T S, Fig. 13) is very narrow. Gyrus temporalis medius (T M, Fig. 13) is unusually broad and in its posterior portion perfectly insulated by sulci.

The gyrus fusiform (Fu, Fig. 14) is divided into two parts by a sagittal sulcus and is posteriorly perfectly insulated. Anteriorly it goes over in the gyrus hippocompi and the gyrus temporal inferior (T I, Fig. 13). The gyrus cinguli (C I, Fig. 14) is a well-developed gyrus. The pentagones anterior medius and posterior (mentioned by Brissaud) (P E N a. m. p., Fig. 14) are easily made out.

On the lateral surface of the occipital lobe are gyrus occipitalis medius and gyrus occipitalis inferior well marked.

On the insula and the other parts of the left hemisphere not mentioned nothing is found worth recording.

RIGHT HEMISPHERE.

Fissura sylvii (f sy, Fig. 15) is 51 mm. in length and at its posterior end is divided into two short rami posterious (*r p a*, *r p d*). From its anterior portion one branch passes upward, which then bifurcates to form ramus anterior ascendens (ra, Fig. 15) and ramus anterior horizontalis (r h, Fig. 15), which latter anteriorly becomes sulcus fronto marginalis lateral (Eberstaller) (f ma_{111}, Fig. 15). Although the two last named sulci communicate, the boundary between them is marked by a deep transverse gyrus (by x, Fig. 15). Behind ramus ascendens the sulcus diagonalis (d, Fig. 15) goes upward, sending forward a branch, which anastomoses with sulcus frontalis inferior. Sulcus diagonalis is shallow, not penetrating down to the insula, and consequently can not be considered as ramus ascendens fissura sylvii.

The sulcus centralis (c, Figs. 12 and 15) commences on the upper surface near fissura longitudinalis. It is slightly curved in its upper part, but its lower part has a straight course.

The sulcus cinguli (ci, Fig. 16) is continuous, but is double in its pars anterior and pars intermedia (Eberstaller) (pa, pi, Fig. 16). Parallel to the lower part of sulcus cinguli the sulcus rostralis (ro, Fig. 16) runs forward, making an incision in the anterior edge of the hemisphere.

The sulcus præcentralis superior (prs, Fig. 11) in its upper part is about parallel with the sulcus centralis, but at the level of the middle of the hemisphere it goes backward and downward, cutting through the gyrus centralis anterior and the gyrus centralis posterior, ending in the sulcus posteriocentralis (p o, Fig. 15). The lower portion of the sulcus præcentralis superior thus has the same course in both hemispheres, dividing the gyri centrales in the same way on both sides. An upper short and shallow branch goes forward from sulcus præcentral superior, and a little laterally to this branch the sulcus frontalis superior (f_{1}, Fig. 11) passes forward. The latter soon divides into two sulci, neither of which reaches the orbital margin. The lateral branch of the sulcus frontal superior (f_{11}, Fig. 11) might be considered as an upper portion of the sulcus frontal medius. The sulcus frontal medius (fm, Fig. 12) starts a little back of the anterior end of the sulcus frontalis superior, branches freely and ends in sulcus fronto marginalis medius (f m a_{11}, Fig. 12), (Eberstaller). The sulcus præcentralis inferior (pr i, Fig. 15) is connected with the sulcus frontal inferior, but ends free, both in its upper and lower end, with which latter it nearly reaches fissura silvii.

The sulcus frontalis inferior (fi, Fig. 15) even on this hemisphere is short and anastomoses anteriorly with sulcus diagonalis (d). From fissura sylvii a sulcus subcentralis anterior (sb a, Fig. 15) is directed upward into gyrus centralis anterior. On the orbital surface a circular sulcus exists, from which three radiating sulci are directed forward and three backward.

The gyrus frontalis superior (F_{1}) is broader than on the left side, but the gyrus frontalis medial (F_{11}) is even in this hemisphere the most prominent. The gyrus frontalis inferior (F_{111}, Fig. 15) is small, with a small operculum intermedian. The gyrus centralis anterior (C A, Fig. 11) is, as mentioned, divided by the sulcus precentralis superior into one superior and one inferior portion. The gyrus, which takes a nearly straight course, is narrow in its upper part, but is otherwise broad. The gyrus paracentralis is oval and anteriorly bounded by sulcus præcentralis medialis (pr m, Fig. 16).

The gyrus centralis posterior (C P, Fig. 11) is also divided by sulcus præcentralis inferior into one superior and one inferior portion. It is broad and takes a straight course.

LOBUS PARIETALIS, LOBUS TEMPORALIS, LOBUS OCCIPITALIS.

The sulcus postcentralis (retrocentralis) (p o, Figs. 11 and 15) is continuous, passes upward from fissura sylvii and ends in a sulcus that arches around incisura sulci cinguli (i c, Fig. 16). This arciform sulcus (p o s, Fig. 11) is probably best considered a part of sulcus postcentralis superior. Behind sulcus postcentralis superior a typical sulcus parietalis superior (Retzius) (p s, Fig. 11) exists, which starts on the mesial surface and then goes transversely over the superior surface, sending one branch backward. The sulcus interparietalis is represented by two sulci. The anterior (i p a, Figs. 11 and 15) has one vertical forward concave part, which forms the posterior boundary of gyrus parietalis ascendens. Between the anterior end of sulcus interparietalis and fissura sylvii is found a short compensatory (Retzius) sulcus, which arches around the end of fissura sylvii. It is identical with the sulcus that Brissaud names sulcus lobuli parietalis inferior (sp i, Fig. 15). The posterior part (i p p, Fig. 11) of sulcus interparietallis is a short angular sulcus. With a short transverse part at its anterior end it helps to form the posterior boundary of gyrus parietalis ascendens. Posteriorly it communicates with the fissura parieto-occipitalis (f p o, Fig. 11) and ends behind this fissure as salcus interoccipitalis (i o p, Fig. 11). Salcus subparietalis (sp, Fig. 16) is anteriorly connected with sulcus cinguli and posteriorly with sulcus præcunei (p c, Fig. 16). The sulcus temporalis superior (t s, Fig. 16) is divided by a narrow gyrus into one anterior portion, which is double, and one posterior portion, which extends high up in the parietal lobe and here joins the interparietal furrow.

The sulcus temporalis medius (t m, Fig. 15) is broken up into several short sulci. Its ascending part sends one anastomosis forward to sulcus temporalis superior and divides then into two branches, which both extend upward, ending (t m, Fig. 11) as deep sulci in sulcus interparietalis posterior. The sulcus temporalis inferior (t i, Fig. 16) is well developed. It communicates with incissura præoccipitalis and joins posteriorly sulcus occipito temporalis (o t, Fig. 16).

The sulcus occipito temporalis (o t, Fig. 16) extends backward to the occipital pole and is joined at its central part by a sulcus lingualis (s l, Fig. 16). A three-stellated free sulcus exists in the posterior part of gyrus lingualis (s li, Fig. 16). The incissura præoccipitalis (pr o, Fig. 15) extends upward on the lateral surface of the occipital lobe, forming a sulcus preoccipitalis. Short branches go out from it forward and backward, which together might be considered to form a sulcus occipitalis lateralis inferior (ol_3, Fig. 11). The fissura calcarina is typical.

The fissura parieto occipitalis (f p o, Figs. 11 and 16) communicates only by a shallow furrow with fissura calcarina and takes on the upper surface a very remarkable course. There it communicates with sulcus interparietalis, but continues further laterally and divides then into two branches, one going forward, the other backward. The anterior branch goes forward and downward and soon joins a longitudinal furrow which runs on the lateral surface of the lobus occipitalis. The posterior branch goes backward, but turns forward again and joins also the above-mentioned longitudinal sulcus (o l_1, Fig. 15). This longitudinal sulcus goes downward and backward and sends, near its end, a branch forward, which anastomoses with another longitudinal sulcus (o l_2, Fig. 15), which enters anteriorly the temporal lobe and reaches posteriorly the occipital pole.

The fissura parieto occipitalis keeps its depth even laterally to sulcus interparietalis and becomes more shallow first at the point of division. The here described course of fissura parieto occipitalis is certainly abnormal and very seldom seen in the human brain. It corresponds to the course the fissura parieto occipitalis usually takes in the monkey brain and to what is described in the brain of the Egyptian by Elliot Smith.[1]

On the upper surface of the occipital lobe exist several small irregular sulci.

The gyrus parietalis ascendens (P A, Fig. 11) is well defined in its upper part, and forms here an irregular gyrus which can be followed to fissura longitudinalis. The posterior part of gyrus parietalis superior forms a plump polygonal gyrus. The gyrus supramarginalis (S M, Fig. 15) is beautifully formed. The gyrus angularis (G A, Fig. 15) takes its regular place, but is cut by the anastomosis betwen the sulcus temporalis superior and the sulcus interparietalis. The gyrus temporalis superior (T S, Fig. 15) is not as narrow as on the left side and continues upward in the gyrus supramarginalis and the gyrus angularis. The gyrus temporalis medius (T M, Fig. 15) is in its anterior part very broad, but becomes narrow in its gyrus angularis ascending part. The gyrus temporalis inferior (T I, Fig. 15) is rather narrow. The gyrus præcuneus (P. C, Fig. 16) is divided by the sulcus præcunei into one gyrus præcuneus anterior and one posterior. The cuneus (C U, Fig. 16) has one sulcus which runs parallel to the fissura calcarina.

The gyrus lingualis (L, Fig. 16) and fusiformis are well developed. The gyrus cinguli (C I, Fig. 16) is well formed and shows the three pentagones very distinctly (PENa PENm PENp, Fig. 16). About the other parts of the hemisphere nothing remarkable.

MICROSCOPIC EXAMINATION.

The pia is normal. The intima piæ runs perfectly smooth over the gyri, but most of its veins are distended with blood and in some places hemorrhages are found, both on top of the gyri and between them. The largest of the hemorrhages may be seen with the naked eye as punctiform. They exist also in the brain substance, usually the white, and are most numerous in the motor region, and in the frontal and temporal lobes, but may be occasionally found in the other parts of the hemisphere and in the central ganglia. They have all the *character of fresh* hemorrhages and must have occurred shortly before death. The blood vessels in the pia and in the brain substance are normal. Their walls are not thickened and no infiltration exists around them, but in the parts of the brain where the hemorrhages are numerous a slight edema is found around some of the veins. There is no measurable change in the thickness of the cortex, and estimations of the number of the ganglion cells have given the same figures as in normal brains. The giant ganglion cells (Betz) are normal, but in the large pyramidal cells and in those of medium size a slight chromotolysis was *frequently met with* (*Fig. 5*). *In the* layers of the *medium sized and the small* pyramidal cells, especially in those parts *of the brain that* showed *numerous hemorrhages*, *many* cells were found showing the degeneration described by Hoche (Fig. 6). The same kind of degeneration was also found in nucleus dentatus.

---

[1] The Morphology of the Occipital Region of the Cerebral Hemisphere in Man and Apes, Anatomiche Anzeiger, vol. xxiv.

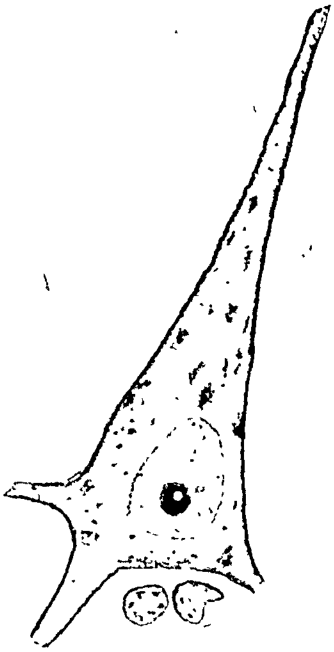

Fig. 5.—Pyramidal cell from the deeper part of cortex. (Leitz system 1/12, ocul. iii.) (Rosin.)

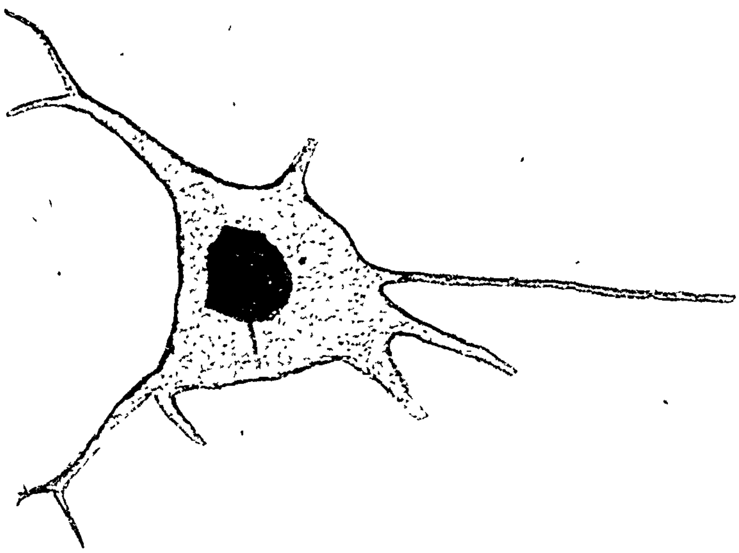

Fig. 6.—Degenerated pyramidal cell from the middle layer of cortex. (Leitz system 1/12, ocul. iii.) (Rosin.)

Notwithstanding repeated trials it has been impossible to stain the neuroglia with any of the elective methods. There seems, however, to exist a *slight increase in the neuroglia* nuclei in the motor region and parts of the frontal lobe, but the increase is so very slight that I do not venture to decide positively if the glia is increased or not.

The *number, size* and arrangement of the medullated fibers correspond perfectly to the normal. In Figs. 7, 8, 9 are reproduced sections from different parts of the brain, and in Fig. 10 a section from a sane man of the same age as the patient.

Section 10 is about 5 microns thicker than the other sections and serves mostly as a control of the reproduction. The thickness of the other sections varies between 15 and 20 microns. They show the different strata and the radiating fibers without *any perceptible deviation from* what normally is found in the corresponding gyri. The ependyma is normal in the lateral ventricles, the aqueductus sylvii and the fourth ventricle. Especially important is that the brain tissue beneath the above mentioned depressions in the frontal lobe was found perfectly normal in all its layers.

The brain here described can be said to have in general broad gyri, but it does not present well formed and regular gyri and sulci. Although there is nothing in the formation of the gyri and sulci that can be classed as positively pathologic, certain features are worth mentioning. Thus the right frontal lobe does not extend as far back as the left, and several of the gyri give the impression of a conformation lacking in proportion and symmetry as, for instance, Brocas gyrus, certain parts of the gyri centrales, parietalis and temporalis. Furthermore, an unusual number of deep anastomoses between the great sulci and, finally, the abnormal development of fissura parieto-occipitalis. It may be that the irregularities mentioned have not any significance, but, on the other hand, they may be signs of a faulty development. As heredity is generally considered one of the most important factors in the etiology of circular insanity, it has seemed to me important to look for formations that could possibly indicate a faulty development and to make the material available to comparison with brains from other cases of the same disease. I deemed it necessary to give a full description of the gyri and sulci with accompanying drawings. The microscopic examination has, as seen, not given any positive results, except the finding of hemorrhages, the slight caromatolysis and the Hoches degeneration, and all these changes have their natural explanation in the typhoid fever of which the patient died. But, on the other hand, the microscopic examination has strengthened the clinical diagnosis, *making it possible to exclude a dementia paralytica.*

One distinct pathologic change has been found in this case and that it is the exostoses with adherent dura. Now the opinion has been expressed that exostoses could perhaps have some influence on the development of a circular insanity by the changes they cause in the cortex. In Dr. Dewey's case, however, there was not found the slightest alteration of the cortex *in that part* of the brain which was exposed to a supposed pressure of the exostoses, and I can not, under such circumstances, see any reason to suppose that the exostoses have had any influence on the insanity in this case.

SOME GRAPHIC OBSERVATIONS OF ANKLE CLONUS.

AUGUSTUS A. ESHNER, M.D.

Professor of Clinical Medicine in the Philadelphia Polyclinic; Physician to the Philadelphia Hospital; Assistant Physician to *the Philadelphia Orthopedic* Hospital and Infirmary for Nervous Diseases; Physician to the Hospital for Diseases of the Lungs at Chestnut Hill.

PHILADELPHIA.

[From the Philadelphia Orthopedic Hospital and *Infirmary for* Nervous Diseases.]

The phenomenon known as ankle clonus consists in alternate extension and flexion of the foot on the leg, repeated a varying number of times, following passive flexion of the foot effected rather rapidly and forcibly and maintained somewhat firmly. It is best induced with the leg flexed slightly on the thigh and supported in the palm of one hand, although it can at times be elicited—as with the patient lying supine in bed—when the leg is fully extended on the thigh. Its presence is, in general, an expression of excessive irritability on the part of the motor path in the lumbosacral segment of the spinal cord, and while it is occasionally observed in cases of neurasthenia and hysteria, it is, as a rule, a sign of organic disease. It can at times be induced in healthy persons by supporting the weight of the body on the ball of the partially extended foot, with the leg flexed moderately on the thigh. Under such circumstances the movement can, and in fact often must be begun voluntarily, and its continuance requires a certain amount of voluntary contribution. In the presence of organic disease of the nervous system, however, the movement, once begun, continues until it exhausts itself, quite independently of the will of the patient, who can neither induce nor prevent it by this means.

The phenomenon, it is thought, is a reflex brought about through the intermediation of an impulse transmitted to the spinal cord as a result of the tension suddenly applied to the muscles of the calf through the Achilles tendon. The flexion of the foot is effected by the anterior tibial muscles, the extension by the muscles of the calf. The latter is commonly attributed especially to the action of the gastrocnemius, but this can be so only when the leg is extended on the thigh, for it is under such conditions alone that the gastrocnemius is, by reason of its origin from the femur, capable of causing extension of the foot. Ordinarily, however, in the study of ankle clonus, with the leg slightly flexed, extension of the foot is effected principally by the soleus. Both anatomically and physiologically the soleus and the two heads of the gastrocnemius may be looked on as representing the three heads of a tricipital muscle, which do not always act together. The same arrangement is observed in the case of other muscles provided with two or more heads.

According to Gowers,[1] ankle clonus is characterized by regularity of movement, slight variation in different individuals and in the same individual at different times. He found the average number of contractions to be nearly 6 in the second. At first he made the limits between 5 and 7, but more recently he has placed the upper limit at 10.[2] In obtaining tracings of the movement he has observed the rise of the lever in the kymographic record to be more sudden than its decline, while the actual amount of contraction and the extent of movement vary in different individuals.

On the suggestion of Dr. S. Weir Mitchell, I undertook a series of graphic observations of ankle clonus, in order to determine if, like the knee-jerk, it could be reinforced by motor influences, with the result that such reinforcement was at times appreciable to the hand of the observer in contact with the foot, particularly after the clonus had been going on for some time, and as indicated in some of the tracings in the form of increased frequency of movement. The clonus was in some instances induced by means of the hand applied to the ball of the foot and in other instances by means of traction applied from behind the patient through an elastic band.

Most of the tracings were made with the aid of two tambours, one of which was either connected with the foot by means of a stiff wire or applied directly to the foot, while to the other was fastened a style that recorded the movement on the surface of sooted paper mounted on a revolving kymograph. In some instances a rubber bulb was employed instead of the tambour applied to the foot.

To study the normal ankle clonus I made a tracing of the movement of my own feet, obtained by resting rather firmly on the ball of the foot with the leg flexed to a considerable degree on the thigh. I found this not entirely easy of accomplishment, and only with a certain amount of volitional contribution. The tracing (Fig. 1) shows a frequency of between 7.3 and 7.6 in the second for the right foot, and between 7 and 7.4 for the left foot, taken separately, with irregularity in amplitude and occasional dicrotism. These figures correspond approximately with those obtained by Alexander James,[3] who, in observations on five healthy persons, found the frequency of the movement to range between 6 and 8 in the second. From his further studies of this subject, James[4] was led to believe that the rapidity of ankle clonus is in inverse ratio to the height of the individual; that the clonus is more rapid in individuals of nervous temperament as compared with those who appear phlegmatic; that it is more rapid in men who indulge in athletic sports than in those who are less active physically; and that it tends to become less rapid as age advances.

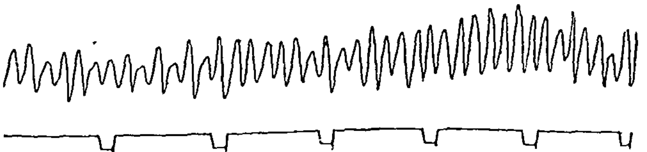

Fig. 1.—Tracing of ankle clonus from a healthy individual; rate about 7 per second; exhibits variation in amplitude and occasional dicrotism; read from right to left.

In a case of hemiplegia I found the frequency of movement to range from 6.6 to 7.2 in the second, averaging 6.9 in fifty-seven seconds, with a progressively lessening tendency (Fig. 2). The tracing exhibits great regularity and a persistent notch between the beginning and the middle of the downstroke of each wave. In a second observation (Fig. 3) the number of movements varied between 6 and 6.4 in the second. The tracing exhibits great constancy in frequency, in rhythm and in amplitude. It is characterized by a persistent dicrotic notch at the bottom of each wave. There was no apparent effect in any way from attempts at reinforcement, as by clenching the fists, closing the eyes or opening the eyes. The range of movement was far more marked than in the tracing from myself, and the curve was far more regular, but in this, as in all other tracings from patients suffering with organic disease of the nervous system, the clonus was entirely involuntary.

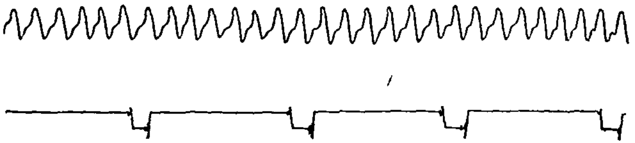

Fig. 2.—Tracing of ankle clonus from a case of hemiplegia, made with the aid of two tambours; rate about 7.2 per second; persistent notch in downstroke; read from right to left.

In a case of myelitis (Fig. 4, Tracings 38, 39, 40), the frequency of movement was extremely variable, becoming, with the amplitude, progressively less, until the movement ceased spontaneously. This would appear to have been due to exhaustion. The average range was from 6.4 to 8 in the second. A dicrotic notch appeared at times at the beginning of the upstroke, at other times a little later, and at still other times in the downstroke. It was noted that when the amplitude was greatest the notch occurred in the upstroke, and as the amplitude became less the notch appeared in the downstroke. The curves in this tracing, as in others, exhibit a tendency to group themselves in pairs. Here also no influence appeared to be exerted by clenching and relaxing the hands. (Tracings 39, 40.)

[2] A Manual of Diseases of the Nervous System, vol. i, p 12, 3d ed.

[3] Edinburgh Med. Jour., xxvi, i, 1880, p. 135.

[4] Ibid., xxviii, ii, 1883, p 1075.

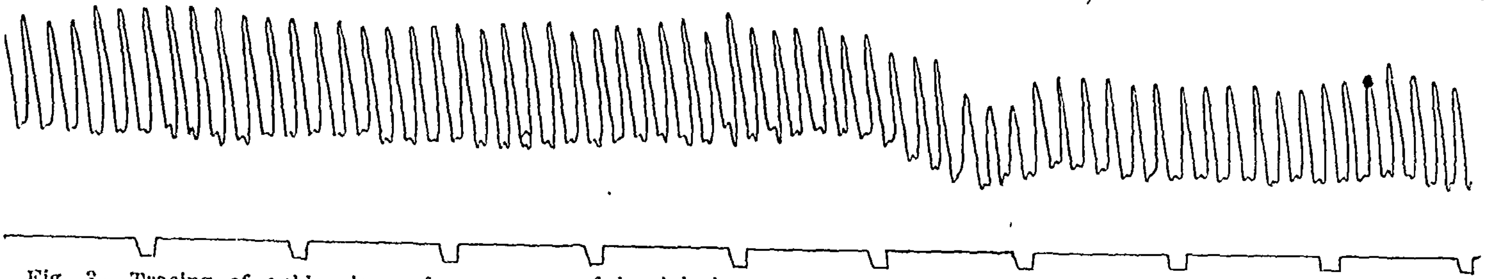

Fig. 3.—Tracing of ankle clonus from a case of hemiplegia; rate from 6 to 6.4 per second; persistent notch at bottom of wave; no apparent reinforcement; read from right to left.

In another case of myelitis, the frequency of movement ranged from 6 to 8 in the second, and some of the tracings showed increased frequency of movement as a result of reinforcement (clenching the hands, closing the eyes). It was also noted that when reinforcement was not thus manifested in the tracing it was distinctly appreciable to the observer holding the foot. In one instance the act of clenching the fists was attended with a temporary reduction in the range of movement and slightly increased frequency, though the frequency was still further increased when the hands were released. In the tracings obtained with the aid of a rubber bulb and a tambour, dicrotism was marked, but this, it was thought, might have been due to mechanical influences, as it did not appear in tracings made with the aid of two tambours. The movement in general appeared to be irregular in frequency and extent.

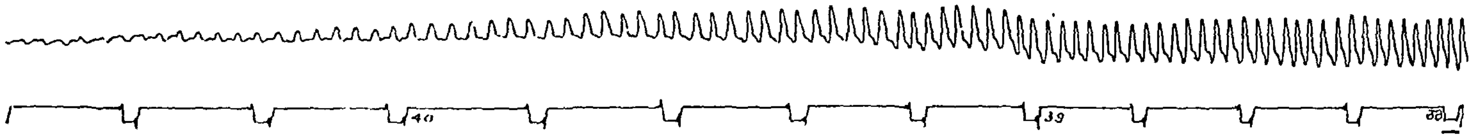

Fig. 4.—Tracings 38, 39, 40. Tracing of ankle clonus from a case of myelitis No. 38, average 7.8 per second. No. 39, hands clenched; average 7.5 per second. No. 40, hands relaxed; 6.6 per second. Exhibits progressively diminishing frequency and gradually diminishing amplitude, with spontaneous cessation; dicrotic notch at first on upstroke, subsequently on downstroke; read from right to left.

In a case of compression myelitis the average frequency of movement in fifty-six consecutive seconds was 6.48 (6.66 in the first fifteen seconds, 6.46 in the next fifteen seconds, 6.41 in the succeeding seventeen seconds, and 6.3 in the final nine seconds), thus exhibiting a progressively diminishing tendency. In another tracing (Fig. 5) from the same case the average rate of frequency for twenty-one seconds was 6.24, with practically no variation, and no appreciable influence was noted from various attempts at reinforcement (R in Fig. 5), such as closing and opening the eyes, clenching and relaxing one or both hands. Some of the curves exhibited a tendency to arrange themselves in pairs.

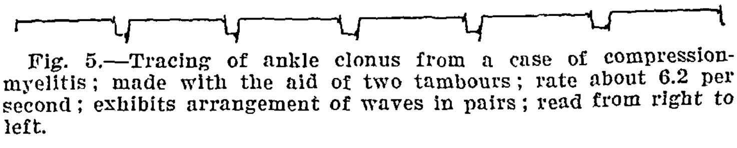

Fig. 5.—Tracing of ankle clonus from a case of compression-myelitis; made with the aid of two tambours; rate about 6.2 per second; exhibits arrangement of waves in pairs; read from right to left.

In a case of lateral sclerosis in a young man, the influence of reinforcement was distinctly appreciable to the examining hand, and it was also shown in the tracings in an increase in the frequency of movement. Thus, with the patient passive, the number of movements in the second was quite uniformly 5.8, while, when the hands were clenched, the frequency became increased to 6.8 and 6.9. These tracings exhibit further a grouping of the waves in pairs, and a distinct dicrotic notch or secondary wave in the descending portion of the curve. In this case tremor of the thighs was induced, evidently through the gastrocnemius and soleus jointly, when the patient stood erect with the legs well extended on the thighs.

In a case of probable porencephaly, the frequency of movement ranged from 7 to 7.3 in the second, averaging 7.2. In addition to the movements of flexion and extension of the foot that constitute ordinary ankle clonus, lateral movements of the foot also could be induced in this case, and these were found to average 6.5 in frequency, with little variation (Fig. 6).

These observations appear to show that there is a not inconsiderable variation in the frequency of the movement of ankle clonus obtained under different conditions, namely, between 5.8 and 8 in the second. In a healthy person it was from 7 to 7.6 in the second; in a case of hemiplegia, from 6.6 to 7.2, averaging 6.9; in a case of myelitis, from 6.4 to 8; in another case of myelitis, from 6 to 8; in a case of compression-myelitis, from 6.2 to 6.7; in a case of lateral sclerosis, from 5.8 to 6.9; and in a case of probable porencephaly, from 7 to 7.3. In some cases reinforcement was distinctly evident, being appreciable to the examining hand and indicated in the tracings by an increase in the frequency of the movement. The failure to demonstrate this reinforcement with greater constancy may be due, in part at least, to the manner in which the reflex was elicited, the extension of the foot, in degree and vigor, being held somewhat in check by the examining hand, or by the elastic band that was employed for the same purpose, so that the reinforcement in either of these directions escaped record. Ankle clonus can not be induced in the usual manner in healthy individuals, and the movement

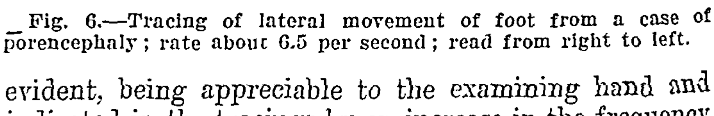

Fig. 6.—Tracing of lateral movement of foot from a case of porencephaly; rate about 6.5 per second; read from right to left.

excited by supporting the weight of the body on the ball of the foot requires in some degree the consent, if not the co-operation, of the individual. It is, therefore, to be looked on as an artificial or false clonus, and accordingly as wanting in the significance of the true clonus. The frequency of the former agrees in general with that of the latter.

MEDICAL EDUCATION AND PRELIMINARY REQUIREMENTS.*

GEORGE H. SIMMONS, M.D.
CHICAGO.

The subject that I shall discuss to-night is one that has many phases, and one on which all do not agree; however, it is one of vital importance and one in which all are interested. I trust that your deep interest in the subject will influence you to bear with me, even though our opinions may not coincide in every particular.

At no time in the history of our country has there been such an unrest in educational affairs as now. The primary and grammar grades have apparently a sure foundation, and will continue to remain about as they are. But above these grades everything seems to be uncertain. Even the high school, we are told, has not an absolutely certain position. What is to become of the college, however, is the question anxiously asked by those who are in the habit of looking through dark-colored glasses. They are sure that the high school will reach up and the university down till the two meet and the college vanishes. And the university; what is to become of it? Is it to be Germanized and developed into a fraternity of professional schools, or Anglicized, and result in simply a combination of colleges? I do not know, but I feel sure that the university will develop until it fits the needs, the genius and the conditions of our country; that the college will remain a distinctive American institution, consequently a necessity. The unrest now prevailing and the evolution now going on will result, I have not the slightest doubt, in establishing more firmly than ever our present splendid educational system, only more perfect than now, and better adapted to the needs of our people.

If there is an unrest in regard to general education, what shall we say of medical education? Unrest is not a sufficiently strong term. Evolution, if not revolution, would better fit the condition.

One of the most prominent signs of the times is the fact that educators are becoming actively interested in a higher standard of medical education, and recognize it as a part of a problem that confronts them. The relation of the professional school to the college and to the university has become so important that a number of conferences have been held by educators to consider the subject, one of the most important in the West being that held last May in Chicago. At this there were represented no less than thirty-two colleges and universities from Massachusetts to California. The report of this conference makes interesting reading, but the most interesting fact revealed to us as medical men is that medical education has become of sufficient importance to engage the attention and earnest consideration of the leading educators of our country. This, I repeat, is encouraging and full of promise for the future.

AN OVERCROWDED PROFESSION.

It may be interesting at the outset to call attention to the fact that our profession is enormously crowded, compared with relative conditions in other countries, and that, if we can deduce anything from educational statistics, this condition is annually becoming worse. At the present time it is estimated that the ratio of physicians to population is one to less than 600. We have twice as many physicians, in proportion to the population, as England, four times as many as France, five times as many as Germany and six times as many as Italy. Yet in each of these, especially in England, France and Germany, there is a cry of oversupply.

In the year 1880 there were 90 medical colleges in the United States, 11,826 students in attendance and 3,241 graduates. Last year there were 154 medical colleges, 27,615 students in attendance and 5,698 graduates. That is, there has been an increase of 64 colleges in twenty-three years, or 71 per cent. The number of students in attendance has increased by 15,789, or 133 per cent., and the graduates increased 2,456, or 75 per cent. During the same period the population has increased less than 50 per cent. It is estimated that 1,700 physicians died last year, and that 500 withdrew from practice, either retiring or entering other callings, making a total loss of 2,200. Let us be liberal and put it at 2,500. This would leave to be added to the profession during 1903 approximately 3,200. Thus there are annually being turned out of our medical colleges twice as many graduates as are required to keep up the present absurdly crowded conditions, even if we allow for the normal increase in population. If the annual output of our medical colleges increases proportionately during the next twenty-three years as it has during the past twenty-three years, it can be easily estimated what the conditions will be then. During the last four years 21.355 young physicians have been poured into the ranks of our profession. At least as many entered the colleges during the present college year as graduated from them last year. Hence, during the next four years at least 27,600 more will be added, making nearly 50,000 new physicians entering the ranks during the first eight years of the Twentieth century. One is tempted to make harsh criticisms when one realizes the cause of all this.

In connection with this another phase of the situation should be noticed. In the past there have been openings waiting on the frontier, even though the cities, towns and villages in the settled part of our country were oversupplied. New states and territories were opening up and developing, and these offered alluring possibilities. Here, there and everywhere on the prairies, among the forests and in mountain fastnesses, villages were rising up and developing into towns and cities, offering homes and a livelihood for the courageous and enterprising. To-day all is changed. From the Atlantic to the Pacific, from the tropical shores of the Gulf of Mexico to the cold borderland of the North, it is settled. There is no longer any undiscovered or any undeveloped country. And no matter which way he looks, or where he may go, the young physician will find the field occupied—another physician is there before him. But he squeezes in somewhere, divides up with others, and succeeds, fails or vegetates, depending on the man and his abilities. It is now a case of the survival of the fittest.

But why take this gloomy view, you say; why show this dark side of the picture? Solely to answer at the outset the argument so often made by raising the standard of our medical-teaching institutions there will not be enough young men enter on the study of medicine to supply the demand.

---

* An address delivered at the dedication of the new building of the Medical Department of Drake University, Des Moines, Iowa, Jan 29, 1904.

The low standard of the medical education of the United States, as compared with that in other countries, has long been the cause of much solicitude. While it is granted that a few of our medical men have taken front rank, and have been equal to the best in any country, academically and in what they have accomplished, the majority of the profession have been poorly equipped professionally, and the low grade of general education has been too distressingly evident.

I speak of the past because the improvement in both respects during recent years has been evident, and we can speak less harshly of the present. I do not mean by this that prevailing conditions are satisfactory, much less perfect; on the contrary, it is only by comparison that we can make use of conservative statements regarding present affairs. Some unpleasant things are bearable—even enjoyable—by comparison. It is not so very long ago that the degree of doctor of medicine was granted after two courses of lectures of four or five months each, and the preliminary requirements were what each individual college thought its best interests required; those interests too often were that the student had the necessary financial ability to pay the fees. The student's interests and future welfare were usually secondary considerations.

TIME REQUIREMENTS.

The most remarkable change which has taken place is the advancement in the length of time required for the medical degree. Twenty-five years ago the colleges that required more than two years of five months were few indeed. Gradually this has been extended until now all schools require a four-year course, although it was only a year ago that the last one was forced into line.

But, for the reason that a college year is a variable quantity, the uniformity of time requirements are more apparent than real. In the United States, including the state universities and privately endowed institutions, including only those which are fairly reputable, there are sixteen that require a nine-month course; nearly forty in round numbers that require an eight-month course, a like number that require seven, and twenty-six that require only six months for the college year. It is rather notable that nearly all the great eastern schools, with the exception of Johns Hopkins, Harvard and the University of Pennsylvania, still require only thirty to thirty-two weeks for the school year, and that all the six-month schools, except two, are in the South. We should realize that those which have nine months for a college year are requiring two-thirds more time than are those with but six months. This variability as to the time requirement is noticeable in your own state. Thus you have your own institution and the State University requiring the full time—a total of thirty-six weeks per annum, while one college requires only eight months and still another only seven months, or a total of twenty-eight weeks. In other words, if the latter school had a five-year course, its total time requirement would then lack a month of being as long as yours or that of the state university.

LACK OF UNIFORMITY IN THE CURRICULA OF MEDICAL COLLEGES.

The lack of uniformity in time requirements is not as serious as the variability in the curricula, not only of the private medical schools, but also of the medical departments of the universities. This can be verified by a study of the catalogues of the various institutions, but especially by an inquiry regarding the work absolutely done. This want of uniformity is noticed primarily in the variability in the time given to definite subjects, in the entire omission of many vital ones, and in the lack of sequence in which the subjects follow each other. This has been recognized for some time, although little, so far as I know, has been done to remedy the evil. A beginning seems to have been made, however, for at the last meeting of the National Federation of Examining and Licensing Boards, a committee, appointed for the purpose the preceding year, made a report in which attention is called to the matter. The committee stated[1] as follows:

> In the interests of a higher and improved standard of medical education, and of interstate reciprocity in licensure, and in order that the degree of M.D. may have a definite meaning, at least an approach to a uniform, fixed value, it is desirable that a minimum standard of requirements for graduation in medicine shall be established and maintained. Heretofore the standards established by the Association of American Medical Colleges, and other similar organizations, have been an outline or definition of a "medical course" in the most indefinite terms. For example, "four years of six months each, in four separate calendar years." Not a word in regard to the number of hours of work in each month or in each year and no specifications in regard to the relative amount of time devoted to each study in the curriculum, the order or sequence in which the studies should follow each other in the course, nothing in regard to whether the work should consist of lectures only, or of laboratory work, recitations, lectures and clinics combined, and especially the relative amount of time devoted to each, especially clinics.

As regards the time spent on the different subjects, we find that of forty representative schools the following variation is noticed:

Anatomy varies from 200 hours to 1,248 hours; physiology from 96 hours to 450 hours; chemistry from 176 hours to 652 hours; histology and embryology from 70 hours to 450 hours; bacteriology from 45 hours to 364 hours; pathology from 54 hours to 512 hours, and so on. If we take the practical subjects of general surgery—medicine and obstetrics—the following absurd conditions are found to exist: Surgery varies from 64 hours to 1,168 hours; medicine from 140 hours to 1,232 hours, and obstetrics from 67 hours to 320 hours. These figures are mostly from the report above referred to.

It should be understood that while I have quoted the lowest and highest number of hours devoted to a subject, some of the schools do not provide for any instruction whatever in certain of the branches. For instance, physiology, bacteriology, pathology, histology, etc., are subjects one or more of which are absolutely ignored by many. The most important subject in the whole curriculum, ignorance of which has ruined the reputation of so many men and resulted in thousands of unnecessary deaths and physical wrecks, is obstetrics. And yet, all that some colleges claim is a course of didactic lectures that can be delivered in a less number of hours than are included in three full days; a subject as impossible to teach with didactic lectures as it is to teach a man to swim by a course in a correspondence school. Clinical, hospital and dispensary work, which are indispensable, are sadly deficient, or are not provided at all in many institutions, except in the annual announcements and catalogues. The same, is true of laboratory work, without which a working knowledge of modern medicine is out of the question.

---

[1] The Journal A. M. A., Aug. 15, 1903, pp. 456 and 457.

I call attention, in passing, to these lacks of uniformity in time spent and in work done, so that you may realize their existence. Each is an important factor in medical education, and each must be considered in the near future.

PRELIMINARY REQUIREMENTS.

Preliminary requirements for matriculation in medical schools has been a live and important question for more than half a century. The main object for which the American Medical Association was created fifty-six years ago was that of elevating the standard of medical education, especially the entrance requirements, and this was one of the principal questions discussed at each annual meeting through its earlier years. Later, the college associations, the American Academy of Medicine and the state boards of health took up the work. The result has been evident in the lengthened course. But the efforts to raise the standard of preliminary requirements were less fruitful, and for years these were lamentably low, so low that even an elementary knowledge of "the three R's" was not insisted on by many schools. The influences at work, however, gradually had effect, and now all require, at least nominally, a good common-school education. Yet there are some so anxious to get students that even this is not always insisted on, and many of those which make pretenses of a reasonably fair standard of requirements use the subterfuge of conditioning to admit a student, and the faculty carefully forgets that the prescribed conditions have not been fulfilled.

In considering the requirements for entrance, we must recognize two standards. The first is that which shall be demanded of all schools and below which none shall be allowed to matriculate students—the minimum requirement. The other is the preliminary educational standard, which is best and most practical for the student and that should be demanded by those colleges which desire to be classed among the best. This we may call the ideal requirement.

THE MINIMUM REQUIREMENT.

It is essential to fix a minimum below which no medical college should be allowed to admit students. This principle will be accepted by all, and I am sure that all will agree on what that minimum should be. In fact, a large number of states have fixed by law the minimum standard, namely, a high-school degree or its equivalent. But when this was done, it was soon realized that it was a vague and uncertain standard, since a diploma from a high school in one state or community represents something entirely different from one in another state or community. This lack of uniformity in high schools so affects all educational institutions above the primary grades that a strong movement is now being made by educators to remedy the difficulty. Your own state has done wonders in this regard during the last five years. This movement will undoubtedly result in the recognition of only those schools that come up to the standard laid down some years ago, which requires four years in which to complete the curriculum. Until the standardization of high schools is perfected, we must specify what class of high schools we mean when we refer to these institutions. This, too, is already done in the medical laws of some nine states, for in them the minimum preliminary requirements are definitely stated to be those of a four-year high-school course or its equivalent. Consequently, medical schools which do not have this standard of entrance are not recognized in such states. Further, the four-year course is specified in the action taken last summer by the Association of American Medical Colleges when it amended its by-laws providing that after July 1, 1905, the 68 colleges holding membership in that body must either withdraw or demand as a minimum requirement for matriculation either a diploma from a four-year high school or normal school, a bachelor's degree from an approved college or university, or an examination in branches which are specified. The public school-teachers of your own state have gone on record regarding this matter. Let me quote from the general principles formulated by the committee of twelve of the Iowa State Teachers' Association. Section 6 says:

> The committee was unanimously of the opinion that all should unite in an effort to have schools of law, medicine, pharmacy, dentistry, etc., require at least the full four-year high-school course. The highest interest of the state and of the nation demands this preliminary equipment for these duties of life and for anything like proper efficiency in these professions.

These principles were enunciated by your own educators some five years ago.

With our system of free education, with high schools of the required standard in every town of any importance, there can be no excuse for the old worn-out plea that it will work a hardship on the poor, self-supporting student who has not had the opportunity for obtaining an education. A young man who is so situated that he can not attend a high school can overcome the difficulty at least by home study, if he has energy, ambition and intelligence. If he has not, it would be better for him, for the profession and for the public that he follow the calling to which his talents are suited; he should not be allowed to enter a learned profession at this age when free education is within the reach of all. Even for the student's welfare and future success, he should not be allowed to start on a career for which he is not qualified. As I have shown, there is not such a great demand for medical men that it is necessary to allow, much less to urge, those to enter the ranks who lack the fundamental education necessary to make success possible. Reasonable requirements are for his interest. With the keen competition, which is yearly growing keener, it is reasonable to suppose that one without them would not have a fair chance with those who start out well qualified. Some may urge that it would be a hardship on the college; that some of the poorer institutions if they raise their standard will lose students. Regarding this, let me quote a paragraph from the report of the committee of the Association of American Medical Colleges:

> That the adoption of such standards as are proposed here would be disastrous to unendowed medical colleges, seems to your committee a most surprising argument to bring forth. For what are medical colleges established? For the benefit of the members of the faculty, or of the board of trustees who may reap some financial profit from them? Surely this is not the case. No medical school can justify its existence except on the ground that it is engaged in a work that is necessary to the community and that it is being conducted in a proper and legitimate way along lines and in accordance with the standards that are demanded by the times. If the statutes and rules of the examining boards of eight of the leading states have already established higher standards, it seems to your committee that it must be a difficult task for any faculty to maintain its right to turn out students on requirements far

below these demands, which are pretty uniformly the very minimum that the conditions warrant.

But what about carrying out the provision regarding entrance to medical colleges? They may agree to live up to the requirements specified, they may emphasize them in their catalogues, but will all the schools enforce them and insist that the student shall honestly pass the required examination, if the examination is left to the college? Not if we are to judge the future by the past. It is well known that there are many medical schools to-day that are not living up to what they now claim. This is a harsh statement, but it is one that will be borne out by facts. So it is not at all impossible that if the examining of the students and the passing on the qualifications are left to the colleges, some of them will be lenient, to put it mildly, in conducting the examinations. This fact has been recognized by certain states. New York has long controlled entrance to its colleges, the Regents of the University of New York, which is not a teaching body, passing on those to be admitted to the professional schools in that state. A year ago Ohio adopted a very excellent provision, for, while it resulted in closing some of the medical colleges, it has been the means of remarkably improving the class of men in attendance and of elevating the general character of the institutions. In that state a principal or superintendent of schools passes on all who enter the medical colleges. Other states, such as Minnesota, Pennsylvania, etc., have some supervision over the requirements, but, so far as I know, none so effective as New York and Ohio. Other commonwealths will undoubtedly soon follow, and Iowa certainly will not be the last one to fall into line. No greater advance can be made than that of taking from the low-grade proprietary colleges the right to say who are qualified to enter. This is fundamental. In England and in all civilized countries except this, the preliminary educational qualifications for the prospective medical student are passed on by those not connected with the medical-teaching institutions. But here, again, we have more encouraging work on the part of the Association of American Medical Colleges, for when it provided for the four-year high-school course as the preliminary requirement, it also adopted the following section:

> This examination [that is, the examination in cases in which the prospective medical student does not have a four-year high-school diploma, or something better] must be conducted by or under the authority of the superintendent of public instruction of the city or state in which the college is located; in no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission.

This goes into effect in July of next year, and I predict that it will prove to be the most effective for good of anything the college association has ever done.

There are, however, 56 regular colleges that do not belong to the Association of American Medical Colleges. Thirteen of these are members of the Southern Medical College Association, which, without doubt, will soon take action and place its preliminary entrance requirements up to the required standard. Of the remaining 43, some four or five high-grade schools, such as Harvard, etc., have either refused to affiliate with or have withdrawn from the college association because they retofore have considered the association's requirements nce and for the degree too low. This leaves The lack o lar colleges of the lowest grade. I think serious as the anxious about them. With professional private medi opinion against them, with the state-licensing boards insisting on what the great majority of colleges demand, and with the increased number of states enacting laws requiring the standard high-school course for matriculation, these low-grade schools must either come up to the standard or go out of existence.

THE IDEAL REQUIREMENT.

We have been considering that grade of requirements that is absolutely necessary for entrance to a medical college, and below which none should be allowed to matriculate. Let us now look at the matter from another point of view—that of the best interest of the student. Is that amount of education represented by the four-year high-school course ample for one who desires to become a well-equipped scientific physician, using the word "scientific" in its broad sense? If so, then it is unfair to force the high-school graduate to waste his time in more preliminary work; on the other hand, if it is not sufficient, it is equally unfair for an institution to encourage or permit a student to enter on his professional course with such a lack of preparation. It seems to me there is but one answer to the question: While the high-school course gives a fair foundation for ordinary life work, it does not provide a sufficient preparatory education for a physician if he is to master the sciences that are the basis of modern medicine. What, then, is necessary? Must the prospective physician have a full course in the college of liberal arts, with the A.B. or B.S. degree, and then the full four-year medical course? There is no doubt that with such a grounding in certain of the sciences in the college of liberal arts, the student would have a comparatively easy time in his medical course. It would give him ample opportunity for laboratory work, for original investigation and for obtaining practical clinical knowledge. No one will deny that this course is an excellent one for those who have the means, the time, the energy and the ambition to take it. The value of a broad foundation in general culture as a basis for any life work can not be overestimated, especially if that work is to be done in one of the learned professions. "Do you believe that a general insistence on a college education for physicians is desirable?" is a question that was asked of fifty medical schools by a committee of the American Academy of Medicine. Twenty-four answered "Yes," and nineteen "No." Probably, however, if these nineteen had been asked whether they thought a college education is desirable or not, that all would have answered in the affirmative. All will agree that a full college course before entering on the study of medicine would be very nice, but all are not ready to say that it is desirable, much less that it should be insisted on. It is too Utopian to imagine that the minimum requirement for entrance to the professional school shall be the full college course. Gradually other schools may join Johns Hopkins, Harvard and Western Reserve, and require the college degree for entrance to the medical department. While there will probably never be many of these, it is well to recognize certain facts. When, in 1895, Johns Hopkins Medical School was opened with the startling announcement that the requirements for admission would be, not only a bachelor's degree in art, but also a year's work in biology, physics, chemistry and a reading knowledge of French and German, great skepticism was expressed regarding the advisability of setting up such a high standard, even by a school so liberally endowed and not dependent on fees from students.

It was declared at the time that the entrance requirements were absurdly too high. Still a dozen students enrolled the first year, and the number has been steadily increasing since. And what is of importance, the school is attracting to itself the best and most promising young men.

The number graduating from the colleges of liberal arts has enormously increased during recent years, and is steadily increasing, and the number of institutions demanding the fullest culture as preparatory to professional studies may possibly increase also, although it is also possible that the number of these will never be very large. Some one has suggested that in the near future such institutions will grant degrees that will be more highly valued and more sought after than will be those of the average school. This, however, is in the future, and probably always will be. The history of education is full of surprises, and one of these may be the abolishment of all the bachelor degrees. If our allotted time on earth were twice as long as it is, the ideal would be the full college course, but when it takes till one is twenty-seven or twenty-eight years of age to complete it, it is not ideal. President Butler in his recent report[2] says, first, that "the stage of development, measured by graduation from a secondary school, is not sufficiently high to serve as the basis for the best type *of professional study, or to enable a university to train* really well-educated professional students." And, second, "that the stage of advancement, measured by graduation from a four-year college course, is so high as to delay unduly the young man's entrance on the active practice of his profession, and to prolong unwisely the period which the student remains under tutelage."

If, then, the four-year high-school course is insufficient and the college course excessive, what is the mean or ideal one? For a standard preliminary training must be agreed on, and what this is must be definitely understood. If the choice of fixing terms of admission be either a four-year college course or the high-school course, the influence of the majority of the universities and professional schools would be in favor of the minimum.

The ideal preliminary education for the medical course is already practically agreed on: Four-year high-school course, followed by two years of electives in a college of liberal arts, the two college years to be devoted to work more or less bearing on, but not necessarily fundamental to, the medical course. Such a course of preliminary work is practical, as well as ideal, for it is within the reach of all, requires but a moderate amount of time to complete the combined course, and because it presupposes that all the branches necessary, *and no more, shall be covered.* The two premedical years in a college of liberal arts, well equipped for teaching the required subjects, give a special foundation for the professional school work, and cover the essentials and these only. Such a course indicates a mean between the absolutely necessary preparatory work, the minimum or high-school course, and the full college course. It means the inclusion of the scientific and practical, and the omission of the so-called academic. It is a standard of requirements that is recognized as desirable, if not necessary, by all educators, without exception. It is the requirement that is already in force in a number of institutions, and will be demanded by all the progressive schools, especially by those affiliated with universities, within the next few years, I am sure. The trend of the discussion in regard to the subject indicates this.

The educated physician of the future must be a scientific man. The new conditions demand it. Pathology, histology, bacteriology, physiologic and physical chemistry, hardly thought of a few years ago, are as necessary to the physician now as once were the rudiments of anatomy, physiology and materia medica. But to obtain a knowledge of these newer branches, so that one can put them to use in every-day practice, requires something more in the way of preparation than an ordinary secondary school education. To be so equipped that he can enter on their study understandingly, the student must know how to use the microscope, must have a general knowledge of biology, of chemistry, of physics, of electricity, of light and sound. These are necessary—absolutely so.

Take, for example, the manner in which chemistry has been taught in medical schools for so many years. The student endeavored to master in the short period available that part of the subject that was supposed to bear on medicine, and consequently could be put to practical use by the physician. No attempt was made to master the whole subject, this being considered unnecessary. With such an *imperfect knowledge of chemistry*, the physician was not able to keep up with its development. The rapid progress of the science and its wider applications to the field of healing in all its branches could never have been anticipated twenty-five or thirty years ago, and the little preparation which the student obtained was very far from fitting him to adapt his knowledge to the new acquisitions that have been made in the last few years. Aside from certain facts that constantly came up in the daily practice, the physician's knowledge of chemistry very rapidly became a minus quantity. With modern medical education, some other course will have to be provided and something better than has been supplied. What is needed is a basis on which to build the ever-increasing structure that science demands. A general knowledge of physiologic chemistry is necessary for the physician who desires to understand modern views regarding dietetics, metabolism, etc., to say nothing of its application to therapeutics and to the action of remedies. Or take the more recent acquisitions of so-called physical chemistry. It is impossible to understand much that is published in the leading medical journals of to-day without a fair knowledge of these modern acquisitions. The young man who has a thoroughly well-grounded knowledge of the general principles of physics and chemistry will be able to understand and utilize the work and theories in this line; without such knowledge he will be more than handicapped. I refer to a thorough mastery of the fundamentals, not the mere acquisition of such chemical facts as may seem from time to time, with the progress of our science, to be of direct application to its practice and teachings. What is true of chemistry is true of other subjects that are fundamental to the science of medicine. This ideal but at the same time practical preliminary requirement, is intended to provide the student who is later to be an educated physician, with knowledge that can be used, and not to be stored up in his brain to evaporate or as an ornament to be admired. A man who hoards up money and does not invest it judiciously so as to bring him returns is a miser, and his efforts to accumulate this hoarded wealth are of no value to him or to anyone else. So it is with him whose education is cultural purely. It is not so-called pure culture that is needed, but knowledge. Culture develops the mind, but after all the mind is developed in mastering the natural sciences, as well as in digging out roots from the Greek grammar.

---

[2] Annual Reports Columbia University, p. 24, 1903.

It is well to remember the difference between medicine of the recent past and that of to-day. It did not need a great amount of learning to acquire a knowledge of anatomy as it was taught a decade go, or of physiology, or of chemistry, as these were then taught. The diagnostic methods of a quarter of a century ago did not absolutely demand any scientific preliminary requirements, for the only instruments of precision used were the stethoscope, the clinical thermometer and the test tube, with two or three chemicals for testing the urine. One of the important advances made through clinical research work is in the diagnosis of diseases. By the examination of the blood we detect the parasites of Laveran, and know that we have malaria. By the examination of the cerebrospinal fluid obtained by lumbar puncture, we eliminate all doubt as to whether or not our patient has meningitis. By microscopic examination of the sputa, as well as by the injection of tuberculin, an early diagnosis of consumption is possible. Widal's test confirms our fears of typhoid, and so on. These things are learned in the medical course, you say; and so they are. But to know them and to be able to use them the student must be able to enter on the study of the branches which are the basis of these diagnostic measures with a broad education and scientific training, or he can never master them. It is almost as absurd to think of one with only a secondary school education entering on the study of the newer scientific branches of medicine of to-day, as it is to think of one leaping from simple arithmetic to integral calculus.

President Eliot of Harvard University, in a discussion in December, 1902, on the relationship of the medical school to the university, said: "I venture to say that any American university now in existence which does not require the college degree for admission to its professional schools, will in twenty years find itself in an inferior position to those universities that do require it." If President Eliot means by a college degree a full four-year college course, then I am afraid his prophecy will not come true; if he means the degree proposed by President Butler of Columbia, namely, one that is obtainable after a two-year course, which shall include work especially bearing on whatever professional course the student has in mind, then I believe he is right, except that instead of twenty I would place the limit at ten years.

THE COMBINED COURSE.

A question which is being energetically debated is that which relates to the combined collegiate and medical course leading to the bachelor and doctorate degrees. It is not very important to us as physicians how the question is settled, so long as medical subjects are not sacrificed for those which are purely academic. If the universities will give the double degree for a two-year course in the college of liberal arts, plus four years in the professional school, it will be ideal. Or, if it be three years in arts and three years in medicine, there is no objection, provided a year of the sciences leading up to medicine is covered in the preliminary three years. But I am not the only one who is fearful that in the end the medical course will be the one to be shortened in the movement now going on. We need not concern ourselves about the bachelor's degrees in science and in arts, still we can not but wonder what meaning there will be to them after awhile. Are the same degrees to be given to one who takes a full four-year college course and a full medical course, making eight years, as are given to another who covers the combined course in six years?

Nearly all the leading universities which have medical departments are now providing this combined course, and the medical course is modified only slightly, if at all, in the curricula that I have examined. If, therefore, the same recognition of the value of the professional school is given in the future as at the present, we should hail with delight this innovation in modern pedagogy. It would be still more delightful if progressive institutions like Drake University would follow the lead of the few which have already done so, and would insist on the six-year combined course, or, what is practically the same thing, demand two years of college work before admission to the professional course.

In the report of the University of the State of New York on "Professional Education in the United States," referring to the call for reciprocity of licensure among the states, occurs the following:

> A uniform standard of admission to practice throughout the United States is impracticable at present owing to varying conditions as to the density of population, educational advantages and general development. Weak states can not maintain the standards demanded elsewhere, and strong states can not afford to lower their standards.

I am a firm believer in the West, and especially in its educational advantages, and I know of no western state that is willing to be classed as "weak." Iowa I am sure is not. With its perfect system of primary and secondary schools, with its numerous colleges, universities and state institutions, it certainly can not be classed as "weak." Do not its people deserve as well-educated physicians as do the people of New York? Are they not willingly supplying the funds to educate their boys and girls and their young men and young women? Are they willing to acknowledge that theirs is a "weak" state, and consequently "can not maintain the standards demanded elsewhere"? It is a libel on your state to even suggest such a thing. And yet the New York report will be correct when it, by inference, classifies Iowa as a weak state medically, if your colleges are not kept up with the better ones, East or West.

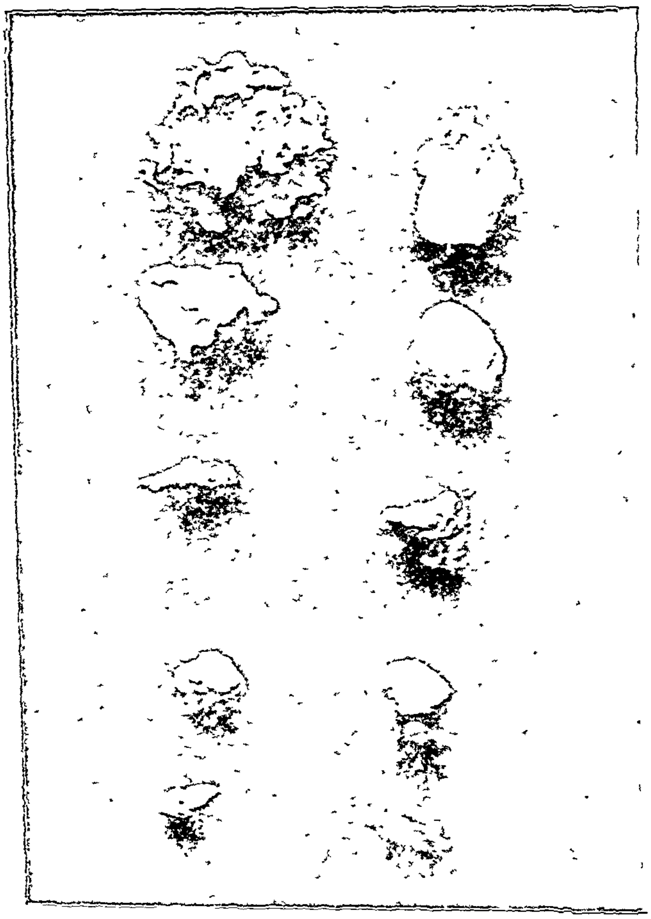
Gentlemen of Drake University, it rests with your institution as much as with any other to keep the standard of medical education in Iowa up to that of any state in the Union. You have the special advantage in being located in the metropolis of the state, where the clinical facilities, if rightly used, are ample. If you keep the medical department of your university a high-grade institution, make an educational standard of admission that is equal to the best, continue to award your diploma only to those who are morally and educationally entitled to it, then will you place Iowa among the "strong" states; then will your people recognize your worth and be proud of your institution. The upward movement is surely, though slowly, advancing toward the ideal; it is for you to say whether your medical department shall be among those which are leading or among those which are to follow.

MULTIPLE LOOSE BODIES IN THE KNEE JOINT.[*]

JOHN PRENTISS LORD, M.D.
OMAHA.

W. C. S., a barber, aged 33 years, admitted to St. Joseph's Hospital Aug. 4, 1903. Family history negative. No history of injury nor other exciting cause. Left knee began to trouble him fourteen years ago. Had attacks of inflammation every two to four years, but later years the attacks were as often as three or four times yearly. He had knowledge of loose bodies within the joint for the greater portion of the time. They produced locking of the joint and inflammation followed. Recently these attacks have been much worse and great swelling and pain resulted. On presentation many loose bodies were easily distinguishable.

Operation.—August 5, 1903, an incision was made as for a Volkmann resection of the knee. The patella was sawn transversely, the lateral and crucial ligaments divided, which exposed the whole articulation. Four bodies were removed from above the patella. One of these was the large one of mulberry shape. Four were removed from under and beside the patellar tendon, and two from the posterior part of the joint, behind the crucial ligaments, these two were, in fact, posterior to the condyles, and much effort was required to dislodge them by the use of curved scissors. The bodies by the patellar tendon required removal by the scissors on account of pediculated villous attachments. In the localities of the attached bodies the synovial membrane was much thickened and hyperemic. On the central surface of the inner condyle the cartilage seemed fibrillated, bruised and torn, as if by the impingement of a body between the joint surfaces. The patella was wired in the approved manner. The ligaments were sutured with chromicized catgut and the skin with plain catgut. Small gauze drains occupied the dependent angles of the incision. A dry gauze dressing was used and a plaster-of paris interrupted splint was applied, reaching to the perineum.



Result.—Healing was primary and the patient left the hospital in good condition Aug. 25, 1903. He returned to his work September 20, though he continued wearing the splint until October 4. Passive motion had been used on removal of splint at night, for two weeks preceding this time. Moderate efforts only were used to restore function. Too strenuous efforts produced irritation and inflammation and this treatment could not be pushed. On account of slow resumption of flexion function the patient returned to the hospital November 22, and under chloroform forcible flexion of knee was made, but on account of apparent separation of the lateral ligaments along the line of incision, flexion was not carried beyond a right angle. A posterior splint and an ice bag were applied four days. Splint removed December 2. Condition good. Dec. 16, 1902, patient had about 30 per cent. of flexion and no irritation in the joint. Little has been done to restore flexion function, because it was considered injudicious to put any considerable strain on ligaments the union of which was immature. A much larger range of motion is now expected, however, as a result of the more active efforts now being used to secure function.

With the knowledge that part of these bodies were behind the condyles (and being informed also that they were the principal offenders), I did not believe it to be practicable to undertake their removal without a free exposure of the joint, believing that there would be greater danger from infection and liability of failure in securing all the bodies, if full command of the joint was not obtained. Even with this advantage considerable difficulty was encountered in removing the bodies from the posterior part of the joint.

My attention was called to the use of this incision for exposure of the joint by the Mayo brothers, C. H. Mayo having reported this procedure for suppurating knee joint.[1] Further experience was reported by W. J. Mayo in a paper before the American Academy of Railway Surgeons at St. Paul in September, 1900. This method has also been used by others in treating that formidable condition, endangering, as it does, lives and limbs.

The feasibility of this procedure for facilitating the successful extraction of these bodies and insuring the success of the operation was clear to me, though no precedent could be found in literature. It is, therefore, presented at this time for consideration. While I succeeded in this single case, I am free to admit that like fortunate results might not follow sufficiently often to justify so seemingly formidable a procedure in a condition not absolutely demanding so radical a course. Discussion may reveal a better mode of procedure. It is conceded that such a mode of invasion would be rarely required, and it is not recommended when not absolutely necessitated by this condition. It has the disadvantage of precluding the early resort to manipulation so necessary in restoring the function of a joint surgically traumatized to this extent, without the result of separating the delicate union before it is sufficiently strong to withstand forced flexion. It is somewhat questionable whether completed restoration of function can be secured after such an operation. In the present case the early return of the patient to his home prevented that supervision so necessary in securing good functional results in a joint thus made liable to ankylosis.

It is not my purpose to discuss the pathology of loose bodies in the knee joint more than to say that the bodies in both of these cases were evidently developed from hypertrophied villi, which, in my opinion, cause these bodies most frequently. Those caused by trauma and separation necrosis, according to some authors, must be most rare. In fact, it is my opinion that these are more ingenious theories than demonstrated actualities.

WHAT SHOULD BE THE PHYSICIAN'S POSITION IN THE BODY POLITIC?*

H. BERT. ELLIS, M.D.
LOS ANGELES, CAL.

Each man, in his time, plays many parts, and the parts which should be played by our profession may well occupy us for a little while.

The logical relation of medicine to sociology has very naturally created some peculiar types of fame for physicians. Oliver Wolcott, a signer of the Declaration of Independence, who led in the foundation of medical societies and journals, is better known as a financier. Benjamin Rush, an alienist, clinician, hygienist and hospital reformer, incurred more enmity by his political conduct than he won fame by his medical science and patriotism; he was a signer of the Declaration of Independence, yet, through criticisms of the "little-great" Colonial nobodies of New England, Virginia and Pennsylvania, he created so much offense that the animosity of their descendants still pursues him, so that as yet the National Capitol has not his monument.

The quaintest instances of extra medical fame of physicians are found in Guillotin and Gatling, the inventors of the guillotine and of the Gatling gun.

It is difficult to say whether Souberbeille owes fame to being a regicide or to his génitourinary surgery in the domain of bladder calculi. He combated the crushing of calculi with as much vigor as he opposed the Bourbons; he survived the French Revolution to take part in the movement that placed Louis Philippe on the throne in 1830 as Citizen King. While Souberbeille voted for the death of Marie Antionette, he insured her better treatment during imprisonment.

It is an open question whether the fame of Erasmus Darwin, the grandfather of Charles, rests more on his medical treatise, Zoonomia, once so great a favorite in the United States, or on his poetry, still extensively quoted. Keats, who was better known as a poet than a physician, unlike Darwin, never actively engaged in practice. Many physicians who have been as eminent in other fields as in medicine might be mentioned, as, for instance, Huxley, Virchow, Weir Mitchell, Hammond and, not to be negligent, our own Bullard.

THE PHYSICIAN IN PUBLIC LIFE.

We have found that knowledge of medicine adds to the efficiency of those possessing it. That it is compatible with many things else—law, preaching, literature, painting, poetry, natural history, exploration, astronomy, invention, both in the arts of war and peace, and adds dignity, honor and usefulness to a man in any profession. But a physician who knows nothing and does nothing but his professional work, is ordinarily a poor physician, and is more likely to be at outs with the whole community. Narrowness of interest creates narrowness of mind, and no vocation needs broader-minded grasp than medicine.

Every physician should have some hobby or recreative employment or study, outside of the mere lucrative side of his profession. Every practitioner of medicine should do more or less politics, and I use politics in its broad sense, that is, to augment the strength and resources of a nation or state and to protect its citizens in their rights and to preserve and improve their laws. In this sense the physician may do much politics without being in any sense a party politician, for there is a positive and vital relationship between medicine and the scientific principles underlying social conditions and phenomena. Whenever medicine has touched politics, politics has been bettered, but whenever corrupt politics has touched medicine, medicine has been smirched.

The relation of social conditions to disease is a topic that is becoming more and more insistent, with the reflections that are the natural accompaniment of advancing knowledge, and it is incumbent on the physician to give more attention to the public health.

For a physician to neglect personal attention to civic and political problems is selfish and unjustifiable. His educational advantages, his specific knowledge of sanitary requirements, his trained judgment, his self-restraint and poise in responsible situations, his familiarity with the vagaries of human nature, and the respect shown him by his fellow-citizens, make him eminently qualified for executive work, and even leadership in civic affairs.

The man of education, brains and capability owes a certain part of his day to the community in which he lives, and to the associations with which his personal success and happiness are due. If he does not give it, he is not doing his full duty to mankind. The greater the advantages he possesses, the greater the call to serve his fellow-man. Few men, as a class, have a greater personal capacity than physicians. Therefore, few owe more to the state.

The physician should aid personally in the endeavor to raise the standard of health, education, art and honesty in the region in which he resides. Time may be required to convince his community that sanitary plumbing, pure water and compulsory vaccination pay. Men of lower ideals may deny that official dishonesty and public indecency sap the vigor of a village, town or city, and inevitably lead not only to higher taxes, but also to diminished personal safety. These truths may be inculcated while carrying on his daily professional work, and he will find that his life is more valuable to his fellow-man than that of the physician who, from laziness, carelessness or timidity, neglects his civic duty, under the pretense that his professional work is too exacting to permit such diversion of energy. The physician's work for the state must have, to be successful, the same quality as his work in medicine. Courtesy and sincerity, honesty and courage, earnestness and intelligence are as essential in the one as in the other. He must be willing in both activities to labor without thought of personal reward.

The membership of physicians on school boards is an undoubted advantage to the public. First, physicians are better able to co-operate and work with the local boards of health, and are, therefore, better able to demand proper sanitary conditions in school buildings and grounds; second, because of the nature of their work, they are better able to comprehend the necessities of the scholars in regard to seating and desks; the tinting of the walls as affecting eyesight; the necessity for correctly lighted rooms, and that the wall boards should not be black. The physician is in a position to insist that the curriculum shall be somewhat elastic, as all children have not the same mental development or capacity. No one is in a better position to judge of the evil effects of child labor, not from the sentimental, but from the physical standpoint, and, therefore, he will be in a position to ask for compulsory educational laws, and see that they are lived up to.

---

* President's address at the Thirty-fourth Annual Meeting of the California State Medical Society, 1904.

There is a feeling abroad, occasionally expressed by physicians and newspaper writers, that there is overpressure in the schools to such extent that children are falling by the way or are made invalids for life. There is another opinion, expressed quite frequently by opponents of the new education, that teachers are doing too much for their pupils, and are thereby helping to create a race of degenerates. "Soft pedagogics" is the term sometimes given to designate the process. Widely divergent as are these criticisms of the present practice in the schools, there is perhaps enough truth in both charges, to put teachers on their guard in respect to the demands they make on their pupils. Viewing the matter solely from the standpoint of health, we may agree that hard, intellectual work of the right kind, done within.proper limits of time, can in no way be injurious to children. It must be as healthful for them to exercise the brain actively as it is for them to exercise the legs actively. It is not hard work that is harmful or repugnant to the normal child, so much as work which is not suited to his needs and powers. Of course, a discrimination must be made between the natural tendencies of the child and those tendencies which have been imposed on him; the former may lead and point the way of the best training, while the latter may indicate the course to be resisted. What is needed for health's sake is not necessarily to lessen the work of the children, but to lead them to work in such a way and at such times that the largest results in mental strength and alertness will be gained with the least fatigue.

Some study cheers and invigorates, while another palls on the mind and wearies it to the point of stagnation. No one will say that the former is nearly so harmful physically as the latter. The two states of mind needed for the physical as well as for the mental well-being of pupils are interest and freshness, the former depending largely on the subject and the way it is presented; the latter on the time in which the recitation or study is carried on.

SANITARY ADMINISTRATION.

In America, we know sanitation and social progress as the power that condemns rookeries; restricts builders; regulates hours of labor and the age of laborers; builds hospitals, public baths and lodging houses; sets aside great areas for parks and playgrounds; establishes sanitaria for consumptives; inspects factories and mines; defines dangerous trades and prescribes territorial limits to those that pollute streams or air; compels vaccination; certifies physicians, dentists, druggists and barbers; quarantines the sick on land and sea, separating mothers from children; condemning property, if need be; rejects immigrants; enters lodging houses, and even dwellings, to determine their sanitary condition; prohibits the adulteration of foods and medicines and penalizes the sale or offer for sale of impure foods for man and beast; presumes to name certain fuel as unfit, and spends millions for waterworks, sewage farms and the support of health departments.

No one community has carried out a consistent and thorough program, but no community has failed to accept the principle that the public has the right and the duty to remove and to prevent disease or conditions that generate disease. We may differ in our theories of disease, or in our belief as to the exact time and place where the public funds shall be used, but we are of one mind that private wealth, private ignorance, private comfort must be of secondary importance, when and where public health is at stake.

Sanitary administration offers a very direct and most efficacious means of reducing the inequalities that even the most conservative capitalist will concede to be incident to our present system of distribution. The meanest wage-earner has already come to associate his health with his capital; his lodge, his creditors and his insurance company are emphasizing that relation. None is so mean as not to wish a higher standard of life. Nothing is easier to demonstrate than that wide and clean streets, playgrounds, hospitals, public baths, tenement and factory inspection help to raise his minimum standard with no sacrifice to himself. In no other field have conservative thinkers and communities taken such advanced ground; conversely, no other field offers so little theoretical opposition or so little prejudice. No other field of administration can demonstrate so quickly and so readily on the platform or by actual test, that there is taxation which benefits without burdening the majority.

In watching contagious diseases in the public schools, it is a great advantage to have the medical inspector directly under the control of the board of education, and not under the board of health, since only about one-seventh of the cases of contagious diseases in the public schools are reported by the health department. Chicago has a rule that when pupils are out four consecutive days, they are excluded until they have been inspected by the proper authorities. They are not accustomed to admit children on the certificate of the attending physician, because such certificates they consider utterly valueless, for the reason that physicians can not easily refuse giving certificates, their livelihood being at stake in many cases.

THE STUDY OF HYGIENE.

It is believed that American philanthropists, whose purses have so often and so generously opened to advance the causes of human knowledge and welfare, have failed to appreciate the opportunities which have lain before them in promoting the cause of sanitation. Every school, college and university should have a carefully developed course of hygiene. Every parent who sends a son or daughter to these places of education has a right to expect that this fundamental subject of life and health shall not be neglected. Competent teachers are needed to instruct the children and youth of the land in the practical business of living wholesome and healthy lives. Sanitary engineers are needed to build sewers and waterworks, drain lands, and lay out and clean cities in accordance with modern principles. Sanitary architects are needed to build healthy dwellings, hospitals, schools and factories, so that the great class of people who are unable to look out for themselves. shall be suitably cared for. Medical officers of health are needed who shall be familiar with the most recent developments of preventive medicine, and who shall be thereby equipped with the best methods of investigation and removing the cause of epidemics. The family physician should be given knowledge, which, as President

Eliot says, shall make him the guardian of his clients in the prevention of disease.

University students are but rarely compelled to study sanitary science, and it is entirely possible for a graduate receiving the highest honors to know next to nothing of the laws of health, on which his very existence depends. But if school children, teachers and university students find a lack of proper facilities for the study of hygiene, what is to be said of the training of that important class of officials charged with the responsibility of guarding public health? As a rule, no training whatever is required of health officers by law, and no provision is made by municipality or state for their instruction.

Excepting Vermont, and in a few other states, it is impossible for health officers to obtain any preparation for their work, except such as they may themselves elect in special courses of instruction in the latest practices in sanitation and preventive medicine. The requirements which must be satisfied before the English degree of D.P.H. is conferred, indicate the character of the training, which, in the opinion of the committee of the American Public Health Association, it is needful for this class of experts to obtain. As at present constituted, the requirements of the English diploma in public health stipulate that the candidate must be a physician, and have had six months' scientific training in hygiene, including sanitary law, sanitary administration, laboratory instruction in sanitary chemistry, bacteriology and the study of preventive diseases. In addition, he must have served six months as an assistant to a medical officer of health.

Dealing with disease is much more complicated than dealing with crime. Our individual danger is ten times greater from epidemic than from murder, robberies, accidents and fires; yet, as a rule, our police and fire departments excite our admiration, while our squad of health inspectors more often arouse our anger and opposition.

Physicians are said to be deficient in business instinct, training and methods, but much depends on the individual. There are many so-called business men who seem to know but little about business, if we would judge by the number of failures and those who go out of business.

The entrance of physicians and scientific men into deliberative assemblies must do good, for the increasing accuracy of science can not fail to make its impress felt in shaping legislative policy. Sanitary and hygienic problems are of ever-increasing importance in national life, and physicians have the general training which makes their views on these subjects of much weight. The interests of commercialism and science may seem antagonistic, but in the broadest sense they are not.

VITAL STATISTICS.

It should be almost unnecessary to recount to a society of physicians the numerous reasons why an accurate registration of vital statistics is absolutely essential to the proper sanitary administration of a state. Vital statistics, and especially correct mortality statistics, are fundamental to a progressive public-health administration. It is as unsatisfactory to attempt to conduct a public-health service, either of a city, a state or a nation, without reliable statistics of mortality based on the immediate registration of all deaths, as they occur, as it would be to manage a large business enterprise without some adequate system of bookkeeping. To know the influence of modern methods of sanitation and prevention of disease on the public health, the statistics of deaths must be accurately known. The progressive health officer must be on the alert to watch the movement of mortality from important diseases, and he can only judge of his success at restricting the same by studying variations in mortality and in sickness.

Reliable records of births are almost of as much importance as are those of deaths. The state owes it to the individual citizen that an accurate record shall be made of his birth and his death. Such records are indispensable for many legal purposes. As regards birth records, there is hardly a relation in life, from the cradle to the grave, in which such a record may not prove of the greatest value. For example, in the matter of descent and inheritance; in the relations of guardians and wards; in the disability of minors; in the administration of estates; the settlement of insurance and pensions; the requirements of foreign countries in matters of residence, marriage and legacies; in marriage in our own country; in voting and in jury and military service; in the right to admission and practice in the professions and many public offices in the enforcement of laws relating to education and child labor, as well as to various other matters in the statutes. As the country becomes more densely settled, and the struggle for existence sharper, many of these matters which have hitherto been of minor significance, will take on a deeper meaning and acquire greater importance.

Nearly every state in the country has attempted to establish a satisfactory system of recording vital statistics, yet up to the present time less than a dozen have adequate laws for the registration of deaths alone, and I believe that there is not a single state, and probably not even a single city in the United States, that has to-day a complete registration of births. This should receive the attention and the active support of every physician in the state, and especially the consideration of our members and our county societies. I therefore recommend to this society that a committee of three be appointed on vital statistics, to co-operate with the Public Health Committee of the American Medical Association.

The executive business of medical schools, hospitals and societies devoted to medical subjects is what may be, and frequently is, termed medical politics. Here the physician has frequent opportunity of showing his skill in carrying on business enterprises, and may exercise the talent of leadership. His success is probably equal to that obtained by men of equal ability in any one other walk of life. He may lack the training of one brought up in an office or bank, but his stock of general information, his knowledge of human nature, his judicial mind, and his habit of scientific accuracy, will soon enable him to equal, if not outstrip his nonprofessional colleague, in executive grasp and precision.

MORE THOROUGH TRAINING FOR PHYSICIANS.

What is essential that the standard of the medical profession be raised and that the physician become a more potent factor of usefulness in the community? Of the students attending professional schools in 1900, 50 per cent. of the theological students had an academic degree; 20 per cent. of the law students and only 7 per cent. of the medical students. Ordinarily, the degree of preparation one has on entering a professional school, represents the character of work he will do in that school. One can not expect to secure physicians wise and comprehensive in diagnosis, keen to discriminate, able to weigh evidence and to relate every fact to every other fact, unless the students who enter the medical colleges are themselves well trained. In professional studies the beginning determines the end, and the end also determines the means and the method; he who is not a good student when he enters the professional school, will not ordinarily be a good student when he leaves it; and if he is not a good student when he leaves the professional school, he will not be a skillful physician when he begins his professional career. The medical profession, as already indicated, is important not only to the individual life, but also to the life of the whole community. The physician should become a public servant, as well as a servant of individuals. He is now set not simply to cure the ills of one member of the human race, but also to keep all men from being sick. He is a trustee for the health of the community. He should be the apostle of health and healthfulness. He is an unofficial member of some unofficial board in every community, and in not a few communities he is a member of the properly constituted board of health. The age of specialists has come, but every general practitioner must, in a sense, be a combination of all the specialists. So wide a range of functions, each of which is of peculiar importance, as important at times as is human life itself, makes very evident the proposition that the physician should have the most liberal, the most profound and the most disciplinary of trainings before he enters on his professional studies. And further, Americans should be in touch with the best methods of the most advanced nations, and our standards should not be lower than those of European countries.

It would be a distinct advantage to American life if the students who have stepped from the farm or the grocery store into the medical school, would return to their farms or their counters. Discipline, as well as culture, training as well as intellect, represent elements which every man who dares to offer himself as the savior of people's lives should possess. One great need of American life at the present time is better trained doctors. The more thorough their training, the better fitted will they be to assume their obligations as citizens in the higher fields of civic usefulness. The mind which has already been sharpened by the methods of one science, takes a keener edge, and that more quickly, when it is put on the whetstone of another science, than does a mind which knows nothing of science, for all sciences are cognate, their methods, though different, are allied. Our profession has been the mother of most of the sciences, and her children are ever coming back to help her. In our art, all the sciences seem to converge—physical, chemical, biological methods join hands to form the complete clinical method.

If the proper organization of physicians existed, a health officer, Democrat or Republican, doing a city such service as to reduce its death rate from 23 to 1,000 per year to 15 to 1,000 per year for successive years, or fighting the dangers of a pest epidemic, would not be turned out of office for partisan reasons, as was recently the case in the city of Buffalo and in our own city of San Francisco.

Very recently, Reed and Lydston have clearly pointed out the fact that medical men have fallen from their high estate of bygone years, and are no longer looked up to and regarded as the leaders in every community. That much of this change in public attitude toward members of this profession is due to the dissensions within our own ranks, there can be no doubt. The influence which the physician of fifty years ago possessed, has dwindled to a mere shadowy suggestion of influence possessed by the doctor of to-day. Instead of in any way controlling the quality and standards of the medicines supplied for our use, we are now become very largely the exploiters of such material as the manufacturer cares to place on the market. Instead of having that representation within legislative chambers which would insure proper protection of the public welfare, we have little or no representation and comparatively no influence. One of the keenest and ablest lawmakers in the land has said that the medical profession could secure any legislation which it demanded, state or national, if it only knew exactly what it wanted and could agree in making the demand.

PHYSICIANS AS LEGISLATORS.

The time has come when we must recognize our duty to the body politic; our duty to the people whose servants we are; our duty to our patients; our duty to ourselves and to our progeny; our duty to the coming generation by taking that place in the affairs of the state and nation which good government, good sanitation, good health laws and proper protection of the public welfare demand. The "Doctor in Politics" must become an established fact and must become a recognized necessity. It is time that at least one representative form every state in the Union should be a member of the medical profession, and that there should be a good number of physicians seated in the Senate. We have too long been like the foolish man in the parable, who buried his talent, carefully wrapped in a napkin. Let us dig up these talents of potential strength and influence and invest them as they should be invested—in the political part of our duty to the people we serve. Let us at once begin to work for that place in our state and national legislatures which the care of the public welfare demands that we should have. To sit quietly back and see inefficient or morally bad men elected to legislative offices and making laws which are worthless or positively and actually injurious to the public, is to neglect that part of our duty which is most essential. The plea that the physician is too busy to take any part in politics is an empty phrase. No physician is too busy to drop a word here, a request there, a hint with another patient, a suggestion to a friend, as he goes about his day's work; and when that day's work is accomplished, and the hints and requests and suggestions are considered. he will realize that much has been done with comparatively little effort.

There are two essential requisites, however, in the perfection of the physician's influence. and position. First, he must ever be a better physician. A higher standard of preliminary education must be required, and the resultant product of our medical schools must possess a far higher average of general as well as medical education. I would recommend that our committee on medical education consider carefully this matter, and place itself in close communication with the similar committees of the American Medical Association and of other state associations, to the end that the matter may be carefully and earnestly gone into and the proper recommendations eventually made. It must not be forgotten that a physician of fairly good average education to-day is relatively far below the standard which he would have held, with no more education, fifty years ago. The general average of education has increased faster than has the standard in our own profession.

THE NEED OF ORGANIZATION.

The second essential to proper advancement and political recognition is organization. We must have a well and a harmoniously organized medical profession before these many things can be brought about. We must work for the good of all, sinking local feeling, petty ambitions, personal differences and animosities, and sticking close to the central organization and central purpose. Each and every one of us must jealously guard the honor of our profession and the solidity of our organization. Every eligible physician in every county of the state should be a member of a county society and should work with and for his fellow-members. The actual conduct of any enterprise must necessarily fall on the shoulders of a few in committees or boards. But the work of the individual member in aiding such committees is invaluable. When your committee says to you "Write to So-and-so a request to take action on such a matter," it is only after knowing what the full conditions are and what can best be done by your help. Do what you can, remembering that it is always the weight of influence which counts, and that if every member of the society acts, we shall bring to bear the weight of more than 1,500 of the most influential class of men in the state.

If there is, in your county, a physician whom you know is not a member of your county society, make it your business to see him or write to him and urge that he immediately apply for membership. Do not wait for the trustees or the council to do this work, but do it yourself and do it at once. An inconvenient location should no longer be regarded as an argument against joining the society, for members now receive the publications and are kept in touch with each other and with the work that is being done. And further, even if a physician is located in a place so distant and inaccessible that he could not attend the meetings of the society, he could add to its importance in the community by the weight of his influence when it is needed. No man knoweth the day nor the hour that such influence may be essential to the successful termination of some issue intended for the good of all.

The California State Journal of Medicine has done excellent work in prosecuting this work of organization, and I commend to you and to your delegates the importance of continuing it in the policy which it has adopted. To the trustees of the council I would earnestly urge the necessity of making every endeavor to even more energetically prosecute the work of organization, and to consider ways and means for working on the physicians residing in counties where there are county societies, yet who remain non-members of such organizations. The time is here; the work is ready and waiting; our duty is writ plain for every man to read; let us then be cowards no longer; let us turn to the work and do it; let us take that place in the affairs of state and nation which it is essential we should take.

School Athletics.—It is certainly time to supervise school athletics more closely, says the *Boston Medical and Surgical Journal*. The possibilities of injury are many, and the manifestations of overwork or overexertion may not be apparent for months or even years. If present conditions continue, they will inevitably bring discredit on the interscholastic games.

Special Article.

THE ARMY MEDICAL DEPARTMENT.

I.

A HISTORICAL SKETCH.

The Medical Department of the United States Army had its beginning on the 27th of July, 1775, when the Colonial Congress at Philadelphia voted a medical establishment, or, as it was then called, "an hospital," for the Army. Prior to this enactment the surgeons of the forces before Boston had been appointed by the colonels of regiments, with the wise proviso, however, on the part of the Provincial Congress of Massachusetts that they should be examined by a medical board named by the Provincial Congress. Of course, among these surgeons there could be no cohesion or effective co-operation, and, as General Washington wrote to the Congress at Philadelphia, affairs were in a very unsettled condition. "There is no principal director nor any subordination among the surgeons; of consequence, disputes and contentions have arisen, and must continue until it is reduced to some system."

The first department consisted of the director general and chief physician, four surgeons, twenty surgeons' mates, an apothecary, a clerk, two storekeepers and a nurse to every ten sick. It may be of interest to mention that the pay of these officers was as follows: The director general, $120; the surgeons, $40; the surgeons' mates, $20; the storekeepers, $4, and the nurses, $2 a month.

Dr. Benjamin Church of Boston was elected director general, and he was given the appointment of all the personnel of the hospital, except the surgeons' mates, who were appointed by the surgeons. Dr. Church had a reputation for culture and professional skill, but was a few months after his appointment detected in treasonable correspondence with the enemy, deposed and thrown into prison. He was succeeded by Dr. John Morgan of Philadelphia, a man of much energy and administrative ability as well as professional skill. He soon gained the friendship and support of General Washington, and these he always retained.

With the extension of the theater of war, the number of surgeons was increased, and Drs. Skinner and Shippen were named chief surgeons for the northern department and the forces on the west bank of the Hudson. The organization was, however, too loose to secure efficiency or concert of action. The relations of the regimental surgeons to each other and to those in charge of the general hospitals were entirely undetermined, and the department surgeons refused to admit the authority over them of Dr. Morgan. There was beside no well-arranged system of medical supply, and in consequence there was much suffering, and complaints multiplied. As has happened since, more than once, Dr. Morgan was punished for the very shortcomings for which he had in vain asked Congress to provide a remedy, and he was dismissed in January, 1777. Congress the next year exonerated him from all blame, but did not reinstate him.

A complete and elaborate organization of the medical department, modeled on that of the British army, was adopted in April, 1777, and Dr. William Shippen was elected director general of the new establishment. Deputy director generals were provided for the northern and southern departments, and under these a physician general and surgeon general in each district, "whose business it shall be to superintend the practice of physic and surgery in all the hospitals of the district." This separation of the practice of physic and the practice of surgery, which obtained in Europe at that time, and in England, has, in civil life, lasted until the present day, necessitated a most cumbrous and awkward dual organization, which soon disappeared under the rudely practical test of war. It is probable that most American physicians at that time outside the larger cities practiced surgery to some extent, in addition to the practice of physic. The regimental surgeons seem from the first to have combined the two arts, and we find in the bill, which, in 1780, reorganized and simplified the medical establishment an explicit provision that "there shall be three chief hospital physicians who shall also be surgeons, one chief physician who shall also be a surgeon, one chief physician who shall also be a surgeon to each separate army, fifteen hospital physicians who shall also be surgeons," etc. But although the medical officers of the Army thereafter appeared to have been both physicians and surgeons, the former title seemed to have been rather reserved for the higher grades, while the title "surgeon" became by the end of the Revolutionary War generic for all medical officers.

At the end of the Revolution the Army was disbanded, except fifty-five men at Fort Pitt and twenty-five at West Point to guard the military stores at these places. The officer highest in command was a captain, and the medical department was reduced to the vanishing point. The Revolution had produced a number of distinguished military surgeons, among whom were Cochran, John Warren, Craik and Tilton, in addition to those already named. The pressure of Indians on the western frontier after a few years prevailed over the morbid fear of a regular army with which our ancestors of a century ago were possessed, and in 1789 a regiment of regular infantry and a battalion of artillery were organized, with a medical service of one surgeon and four suregons' mates.

The War of 1812 brought an army again in the field, but as the medical department was without a head and the surgeons had not even assimilated rank, good medical administration was impossible. In March, 1813, Congress created the positions of physician and surgeon general and apothecary general, the latter to act as assistant to the former, and as medical purveyor. The surgeons were divided into hospital and regimental surgeons, of which the former were superior in rank and pay. Both had mates or assistants, and there were in addition post surgeons who ranked with the mates.

The title of surgeon general appears first in the Act of May 14, 1818. Joseph Lowell was appointed to this position, and in that year he made the first annual report of the surgeon general to the Secretary of War, and also drew up a set of regulations for the medical department. He remained for eighteen years at its head, and during that time by his ability and force of character, shaped and organized the corps of army surgeons into a coherent and efficient medical staff. He was succeeded by Thomas Lawson, a man of strong character and fine professional and administrative abilities, and withal a brave and ardent soldier, and a most original character. He entered the Navy in 1809 as surgeon's mate, but left that service for the Army in 1811. His service as a medical officer of the Army covered the remarkable period of fifty years and three months, and included active and distinguished service in the War of 1812, the Indian Wars and the Mexican War. When he became surgeon general, in 1836, medical officers were without military rank, and in addition to the great disadvantages of such a status, suffered frequently from the insolence and contempt with which the line officers of that day, following the traditions of the British service, were inclined to regard the medical profession. Surgeons, for example, were not entitled to a salute from enlisted men, and when serving on boards were ranked by the youngest subaltern in the service. In the new uniform, adopted in 1839, they were allowed a sword, but not the officer's epaulettes, an aiguilette being prescribed instead; "a piece of tinsel on one shoulder," as Lawson contemptuously described it.

To establish and maintain the dignity of his profession and his corps, was to Thomas Lawson a sacred mission, to which he devoted himself with such courage, pertinacity and keenness of wit that he achieved success in all the important claims advanced in behalf of his corps, culminating in the Act of Feb. 11, 1847, which conferred on medical officers the assured and honorable status of definite military rank. It is a tradition in the service that on the passage of this act the grim old fighter sent around to medical officers a confidential circular to the effect that now that they had the status of officers they must promptly challenge any other officer who failed to show them proper respect.

The medical service of the Mexican War seems to have been performed with the same efficiency, courage and devotion to duty which marked all the operations of the small but glorious armies under Scott and Taylor, and such men as Satterlee, Tripler, Simpson, Cuyler, Wright, Moore and Barnes laid in it the foundation of reputations which were destined to grow under the far wider responsibilities of the Civil War. In the fierce assault of Molino del Ray, Assistant Surgeon William Roberts was killed and Assistant Surgeon James Simons was wounded.

The thirteen years which intervened between the Mexican War and the outbreak of the Civil War were years of activity and progress for the medical corps, although the Utah Expedition against the Mormons in 1858 was the only military event of note. An important advance in the standard of the examination for admission was made in 1849, when a knowledge of Latin, of physics, of practical anatomy in the form of dissection, and clinical experience acquired either in a hospital or in private practice were made prerequisites. In 1850 the Medical Department of the Army was first formally represented at the annual meeting of the American Medical Association.

(*To be continued.*)

Oxygen as Aid in Labor.—Dr. G. Lapenta, New York, has found that inhalation of oxygen is a most valuable aid in labor. It relieves the dyspnea and cyanosis and induces anesthesia to a certain degree, all the functions returning nearer to normal and the progress of delivery benefited in consequence. In his article on the subject in the New York *Gazzetta Medica* for March, of which he is the editor, he states that the results have been invariably brilliant in more than 50 cases in which he has used the oxygen as an auxiliary for the uterine forces. The labor pains were always materially reduced in intensity while the contractions of the uterus became rhythmical and more energetic. The patients afterward feel better instead of being depressed as when chloroform is used. The oxygen evidently has a favorable influence on the entire nervous system and revivifies the nerve centers, which in turn react on the muscles. The new vigor is accompanied by a slight, transient anesthesia, sufficient for the purpose desired.

THE NEXT STEP IN ORGANIZATION.

As the date of the annual session of the Association rapidly approaches, some observations on the new form of organization become pertinent. The American Medical Association is indeed and at last what the name implies. The medical profession of every state now has equal voice—proportionate to its numerical strength—in the affairs of the Association. The House of Delegates is a truly American representative body, made up of men elected to do the will of their constituencies—the state medical associations. The experience of the last two meetings has amply demonstrated the working value to the profession of the House of Delegates. A moderately small representative body of picked men really deliberates on and carefully disposes of many of the practical medico-social, medico-legal, medico-political and medico-material problems constantly puzzling us as a well-defined professional unit in the social order of the age.

In the majority of the states the profession has with avidity adopted the uniform plan of organization for the state medical association. In some states practically the same method of organization has been in force and under trial for years. The test has proved it suitable to the needs of our profession. By a few the new form of organization is spoken of and written about as an "experiment"; not, however, by any one familiar with the medical history of Alabama, of Connecticut, and of two or three other states. It is only a well-tried expedient lately adapted to the American Medical Association and to the state medical associations that had not already adopted it.

It is particularly desirable at this period to remind ourselves of certain fundamental features of the plan of organization that have an immediate practical application. Of these, the chief one is the independence and basal importance of the county medical society. This is now the sole unit of organization and the only arbiter of membership in the organization. The state medical associations have for members all the physicians whom the county societies in their respective territories deem eligible to medical fellowship. The business of the state associations is conducted by a delegate body chosen freely by the county societies in true American fashion. This state representative body, beside having charge of the material interests of the profession of each state, also elects delegates from the state association to represent the state in the House of Delegates of the American Medical Association.

Therefore, it follows that the county medical societies of each state conjointly and directly determine the whole policy of the profession of their state toward a multitude of important practical problems, and indirectly they now just as certainly control the course of the American Medical Association. This is the great new fact of our present system, and it should be well learned and thoroughly appreciated. By instructing its delegates, by memorial, by conjoint action with other county medical societies, whereby it is determined that the delegates from that state to the American Medical Association shall follow some certain predetermined course, the county medical society is in position absolutely to control the great national organization.

All this is but drawing attention to the fact that at last we have a coherent and effective and truly representative form of organization.

Finally it follows that now is the time for the state medical associations to determine what they wish the American Medical Association to do this year. It is time to draw up, consider and adopt resolutions and memorials asking the American Medical Association to give attention to whatever may be considered as pressing problems. The time has come to see that the delegates from the state are instructed to register the will of the profession of the state in the national House of Delegates. In the assumption of these functions the county medical society finds itself a real power in medical affairs, because all its members are members of the state association, and because its delegates share in the election of delegates to the American Medical Association. It is no longer local and provincial; it has a voice in the affairs of the medical profession of America. The destiny of the profession is in its hands. It determines who shall be the "members" for scientific purposes of the state association and also of the American Medical Association. By close organic affiliation with other county societies it makes the state association a great and powerful organization.

The county medical society, then, absolutely and directly determines the membership of the national body, and through delegates elected in proper representative form and through its members acting as the state association, it wholly controls the business side of the national Association's activities. Submit these facts to your neighbor who does not belong to your local society and who is eligible. Let him see that medical societies are real living organisms, registering the will and expressing the sentiment of the medical profession. See to it that your local society makes the state delegates ask the assembled delegates from all the state associations to do that which you think should be done for the good of all physicians by the representative medical organization of America.

ARTIFICIAL IMMUNIZATION AGAINST TYPHOID FEVER.

A safe, harmless method of artificial but active and consequently more or less permanent immunization against typhoid fever would be a most valuable addition to our other means of prophylaxis. In times of war, and in the case of sudden epidemic outbreaks, due, for example, to the unexpected contamination of the water supply of a city, much good might be accomplished by means of artificial immunization. Then, again, nurses and attendants on typhoid patients are exposed in so many ways to infection that a certain number fall sick in spite of the greatest care. Of 35,647 cases of typhoid fever collected by Schüder, 1,179, or 3.3 per cent., occurred among nurses and attendants.

Various methods have been proposed for the purpose of securing an active immunity without danger and with as little disturbance as possible of the health of the individuals. As in the case of pest and of cholera, cultures killed by heating to 60 C. or so have been used mostly, Kolle in 1896 being the first to give such injections to human beings in whom there developed, to at least the same degree as in convalescents from natural typhoid fever, the same reactions of immunity as in animals actively immunized. Prophylactic injections on a large scale have been carried out by Wright among British soldiers in India and in South Africa, the resulting statistics on the whole being favorable to the method. Unfortunately, the general as well as local reactions following the injections by Wright's method were rather severe.

Recently Bassenge and Rimpau,[1] as well as Wassermann,[1] have studied this question, particularly with the view to technical improvements of the methods and to elimination, as far as possible, of the reactive symptoms, local as well as general. Bassenge and Rimpau used heated bacillary suspensions. Three injections were given, the first containing approximately one-fifteenth of a milligram of an eighteen-hour agar culture; the second one-seventh and the third one-third. In each case the total quantity injected was 1 c.c. The effects were studied carefully in eight persons. The general reactions were rather mild, varying somewhat in different persons, the climax being reached in six to eight hours. The local reaction consisted of swelling, redness and a little pain. In no case were the effects at all serious, the symptoms lasting less than twenty-four hours. The agglutinative and bacteriolytic properties of the serum were tested before the injections, and several times afterward. In each case a marked increase in these properties developed, becoming equally as marked as in typhoid convalescents, if not even better. The bacteriolytic power (Pfeiffer's immunity reaction) was determined by finding the minimum quantity of serum able to protect guinea-pigs against fatal quantities of typhoid bacilli injected intraperitoneally. Nothing definite can be said as to the duration of the immunity conferred in this way, because the observations have not been carried out long enough as yet.

Wassermann points out that practically all experiments along this line have been governed by the idea that the more virulent the cultures used for injections the more pronounced would be the resulting immunity. His experiments on animals, however, show that virulence is no real indication of the immunizing power of a typhoid bacillus; the degree of immunity depends on the power of the particular culture to unite with the cell receptors (which is in full accord with Ehrlich's theory), and this power may be more or less independent of virulence as ordinarily determined. In order to secure a permanent material for immunization and accurate dosage, Wassermann recommends a powder obtained by evaporating in vacuum the fluid which results when typhoid bacilli in suspension are killed by heat and allowed to digest themselves (autolysis). He also suggests that several strains of bacilli should be used in preparing this powder, so that the resulting immunity may be "polyvalent," that is, directed against as many bacillary strains as possible, because different strains may not all be susceptible in equal degree to the antibodies present in immunized persons. These suggestions also apply to artificial immunization against cholera.

From this brief review it is seen that a good experimental basis is being laid for a practical, harmless, artificial immunization of human beings against typhoid fever. Wassermann's improvements of the methods, which so far have been tested only on animals, should be carried into effect in a carefully conducted series of experiments on human beings. We believe that there is a definite though somewhat restricted field for this form of prophylaxis, which now promises to be both simple and effective. It would surely prove welcome to physicians and laboratory workers, whose duty may bring them into close and prolonged contact with typhoidal patients and typhoidal materials of all kinds.

PROTOZOAN PATHOLOGY.

American medicine is just now experiencing a boom in protozoa. Following the work of Gaylord and the New York State Board of Health Cancer Laboratory, urging as the most probable cause of cancer certain bodies resembling protozoa, we have had the reports from Councilman and his coworkers in Boston concerning the protozoan etiology of variola and vaccinia, and also the observations by Mallory of certain structures in the skin in scarlet fever, which he considers probably protozoa, and to which he is inclined to ascribe etiologic importance. In Ann Arbor, Novy and McNeal have succeeded in cultivating the trypanosoma, an important step in the study of parasitic diseases. Wilson and Chowning have apparently found the cause of the peculiar and fatal spotted fever of Montana to be an organism of the same sort. Again, the demonstration by

---

[1] Festschr. z. sechsigsten Geburtstage von R. Koch, 1903, pp. 315 and 526.

Reed and Carroll that the causative agent of yellow fever is transmitted by an intermediate host, strongly suggests an animal origin for this disease, and by inference a protozoa.

Yet with it all there has been much indecision on the part of the medical public as to how much importance is just now to be attached to the numerous reports of discoveries of causative agents among this group of animal forms. We have so long and so often heard the cry of "protozoa," and failed to hear any corroborative chorus, that it is not surprising that the conservative man is inclined to be more skeptical toward claims for protozoan etiology than he would be toward bacteria. Indeed, it often seems as if everything possible had been saddled on the bacteria, and that all that is left, from measles to sleeping sickness, is to be credited to the animal kingdom. The nature of the protozoa is such as to make them much less satisfactory subjects of consideration than the bacteria. Because of their inability to grow on culture media, with a few possible exceptions, it is impossible to impose the satisfying requirements of Koch. Because of their delicate structure, variability and particularity toward stains, and especially the manifold forms that they may assume during their life cycle, it is difficult or impossible to fulfill even the first of these requirements, viz., that the suspected organism be found in all or nearly all cases of the disease. And, so far as experiments show, they are probably more limited as to the variety of hosts in which they can grow than are most of the bacteria. Therefore, the best possible proofs that we are likely to have of the specificity of any protozoa will probably always appear weak when compared with the proofs available for the bacteria. At the present time we are limited to morphologic studies, either of the tissues and blood of the infected animal or during the life cycle in the body of the intermediary host, and morphologic proofs of causative agents are far from satisfactory.

American investigators have been fortunate in being able to enlist the services of Professor Calkins of Columbia University, who, having studied these forms of animal life previously from the standpoint of the zoologist, is able to attack the problems from a different point of view and action than the pathologist. He is, therefore, not influenced by the same bias which possibly might hinder the progress of the medical scientist, nor is he guided by the same line of experience. His conclusions are, therefore, of peculiar interest, and they are set forth in the "Fourth Annual Report of the Cancer Laboratory of the New York State Board of Health," with which laboratory he is officially connected as consulting biologist.

As is well known, Professor Calkins has collaborated freely b. Dr. Councilman in his studies of the "smallpox 'his statem,"[1] and is fully convinced of the certainty of its etiologic importance. In his own words, "the question as to the specific organism of smallpox is no longer open to doubt." With this statement, however, there are many pathologists who will take issue, for however weighty the arguments of these observers may be, the story is by no means complete; and until it is, many fairly conservative men will assume the privilege of skepticism, no matter how much and how sincerely they hope that the honors of the successful presentation of the cause of smallpox may fall on an American, and on so deserving a one as Dr. Councilman. The bugaboo of "artefact" is always present in these morphologic studies, in which fixed and stained specimens must be used, and even with the variola organisms Professor Calkins admits that "owing to the small size of certain stages and absence of differentiation, I can not always distinguish them from artefacts." Yet the other features present are sufficient to convince him, as a zoologist, that the *Cytorycetes variolæ,* described by Guarnieri, and worked out in certain phases by Councilman and his associates, is the actual cause of smallpox, and also that "many other diseases belonging to the same group as smallpox (the exanthemata) will, in all probability, be shown to have a like etiology."

Carcinoma also appears to him to represent a result of protozoan invasion, and what he seems to consider as an important obstacle in the discovery of this cause is suggested in the following: "Inclusions in carcinomatous tissues should be studied by specialists trained to the study of protozoa, and not left exclusively to pathologists, many of whom regard all structures which are to them incomprehensible as some type of degeneration product of the cell." This is certainly a point well taken, although there will be a ready retort from the pathologists that the zoologist is fully as ready to call almost any sort of cell inclusions protozoa. The work already done on the morphology of cell inclusion in cancer seems to Calkins "to justify the provisional assumption that these cell inclusions are neither secretions, as Greenough describes, nor degeneration products of the cell, as most pathologists very generally describe, nor are they modified centrosomes and spheres, as Borrel maintains, but phases of an organism belonging to the group *Protozoa.* This is based on the discovery, not only of ameboid forms inclosed within the characteristic capsule which is typical of the so-called 'Plimmer's bodies,' but on reproductive phases, on nuclear changes and on characteristic morphologic protozoan structure." That the question of the etiology of cancer is far from settled, is indicated by the following statement: "While such structures justify the provisional assumption of a protozoan organism in cancerous tissue, they do not justify the contention that their presence is the cause of cancer, nor is there enough evidence as yet to indicate in what group of protozoa the possible organism belongs." An interesting point is made that it is not absolutely essential that such parasitic protozoa should

---

Journal of Medical Research, Feb., 1904, for the ... cilman and his associates.

possess a nucleus of the ordinary type, it being possible that living as intracellular parasites there is no need of a functional nucleus, except for reproduction, any more than a tapeworm has need of a digestive tract.

EXPERIMENTAL THERAPY OF TRYPANOSOMIASIS.

Recent investigations have shown that animal parasites called trypanosomes cause important diseases among domestic animals, especially horses, in tropical regions. Furthermore, certain facts have come to light that indicate that trypanosomes may play an important part in a certain Africa disease, known as sleeping sickness. At the present time the favorite method of procedure in specific therapeutic experimentation is by the way of immunization, i. e., attempts are made to secure antiserums.

Purely experimental pharmacologic therapy of infectious diseases has been greatly neglected. In view of the absolutely curative action of quinin in malaria—a disease caused by highly organized parasites of animal nature—it certainly would seem worth while to study the experimental therapy of trypanosomiasis by purely pharmacologic methods, as opposed to immunization. Already progress is reported. Laveran and Mesnil found that sodium arseniate has considerable antiparasitic effect in the case of mice infected with the trypanosomes of nagana, but unfortunately this effect was only temporary. As already mentioned in The Journal (pp. 1190-1256), Ehrlich and Shiga[1] resorted to the use of certain dyes belonging to the benzopurpurin series, and after some experiments they secured a special preparation which they call "trypanroth," which is easily soluble in water and not very toxic to mice. In this case the mice were infected with blood containing the trypanosomes of mal de caderas—a South American disease of horses—and usually death followed in four to five days. When infected blood and the solution of trypan red were injected simultaneously, but at different points, no disease developed. Injection of the red one to two days after infection also had marked effect, but relapse occurred even so long as sixty-five days later. By repeated injections definitive cure could be accomplished. The same result followed the giving of the trypan red by the mouth. In rats they found a much greater tendency to recidivation, and guinea-pigs and dogs proved less favorable still, the trypan red in them having only a slight effect. In mice infected with nagana trypanosomes the action of the red was much less favorable. Hence probably much further work must be done in order to discover other agents with curative action on other forms of trypanosomiasis than mal de caderas in mice. Trypan red does not kill the parasites in the test tube, but only within the body, which Ehrlich and Shiga found to remain protected only so long as the coloring matter was present in the circulating blood, i. e., only for two to four days. They conclude that under the influence of the dye, as the result of reactive phenomena, there develop antiparasitic bodies which soon disappear. By repeated reinfections and curative injections it was found possible to prolong the period of immunity for twenty to thirty days. In this case it would seem not unlikely that it concerns a real active immunity due to the repeated infections and destruction of the parasites, but even this immunity, after all, is only of brief duration.

It is, therefore, easy to understand that in these cases residual germs may give rise to relapses as the immunity passes away. Perhaps something similar occurs in relapses in malaria and in syphilis. These interesting experiments are also suggestive of a connection between pharmacology and immunity. Pharmacologic agents in directly or indirectly destroying parasites within the body may set up reactions that eventually lead to immunity.

CHRONIC CONSTIPATION.

Chronic habitual constipation has long been the subject of widely different views so far as its importance as a factor in disease is concerned. On the one hand, we have those who, like Bouchard, Glènard and Feyot, hold it responsible for the gravest symptoms, attributable to autointoxication from resorption of fecal matter; on the other hand, those who, like Osler and Boas, think that autointoxication from this cause is rare, and that the great majority of persons with chronic constipation suffer little inconvenience from this condition. The experience of most practitioners bears out the latter view. Every physician knows of persons in fair health who have infrequent and scanty stools, while cases are on record of apparently healthy individuals who habitually went from two weeks to several months without any evacuations from the bowels. This "primary functional habitual constipation" is almost universally attributed to an abnormality of the nerves of the intestinal wall, leading to a lessening of normal peristalsis—atonic form—or to a spasmodic contraction of the muscular coat—spastic form. Nothnagel adds to these a form due to atrophy, congenital or acquired, of the muscular coat. This theory, almost unanimously accepted, was called in question two years ago by Strassburger,[1] who advanced the theory that the diminished peristalsis in chronic constipation is due, not to any abnormality in the innervation of the intestine, but to absence of the usual stimulus to peristalsis. Normally the stimulus is furnished by the products of bacterial fermentation, the acids, soaps and gases. Strassburger succeeded in demonstrating the fact that the feces of chronic constipation are abnormally poor in bacteria, that while normal twenty-four-hour feces contain 88 g. of bacteria (after all fluid has been removed by evaporation), the feces of constipated persons contain only from 2.6 g. to 5.5 g. The reason for this diminution he finds in the composition of the feces, which are almost devoid of remnants of the ingested food, such as muscular fibers and cellulose sheaths, the usual nutrient medium for the intestinal flora. Strassburger thus concluded that the underlying cause of chronic constipation is a too complete utilization of the ingested food. These statements of Strassburger seem to have just received confirmation at the hands of Lohrisch,[2] working in Schmidt's clinic in Dresden. Lohrisch finds that the amount of feces from normal persons averages 249.5 g. per day; from constipated persons only 125.5 g., and this difference is not due to abstraction of fluids, for the difference in weight of the evaporated feces in the two cases is still greater—59.3 g. for the normal and only 33.9 g. for the constipated. The diminution affects all of the constituents, but most markedly the nitrogen, which is reduced to 1.5 g. from the normal 2.9 g.

[1] Ztsft. f. klin. Med., 1902, vol. xlvi, p. 413.

Weakened peristalsis alone, as in the constipation caused by the administration of opium, gives rise to smaller stools, but this is due only to abstraction of fluid, the solid feces are equal or even greater in amount than under normal conditions.

It might be said that this diminution of the normal intestinal contents is due to an abnormal activity of the bacteria in the intestines, to excessive fermentation. But this is disproved not only by ordinary clinical experience, which finds symptoms of abnormal fermentation very rarely in these cases, but also by Strassburger's researches just cited, and by the fact that the feces from chronic constipation show no signs of such a process. They are almost odorless, neutral in reaction, and may even be kept in the incubator without decomposing.

Chronic constipation, therefore, is, according to these investigators, due to diminished motility of the intestinal wall, but this is in its turn due to the overutilization of the ingested food in the small intestine. The feces in the large intestine are poor in nutriment, and can not support bacteria enough to produce the acids and gases of decomposition which normally excite peristalsis. It follows that a rational therapy would be directed not to strengthening the motor apparatus of the intestines, but to the increase of indigestible substances in the diet in order to provide nutrient media for the intestinal bacteria.

SPINAL COCAINIZATION.

In a recent article, Bier,[3] whose name is familiar as the perfector of Corning's suggestion of anesthesia of the spine, announces that with the use of the suprarenal preparations he has relieved the operation of many if not all of its dangers. Their use, he says, renders it possible to insure strict localization of the cocain to the point where its action is desired. It had been known before that adrenalin injected into the lumbar sac was tolerated well by animals, and Bier applied this fact in his clinic. He has also utilized the method in one hundred and twenty-one cases in patients ranging in age from sixteen to eighty, mostly men, much debilitated and unable to undergo general anesthesia. In no case was there any unfortunate complication save a rather severe headache, lasting for a considerable period in a few instances. For the details of this method we must refer to the abstract, but it is a notable fact that so cautious an operator as Bier should be so positive in his asseverations as to the harmlessness of the method. As regards its comparative comfort, he admits that while some patients express for it a preference, others prefer general anesthesia, and some find both equally uncomfortable. It would appear from this evidence that the probability of spinal anesthesia—a name to which Bier objects—has probably come to stay among surgical procedures, but it will be desirable to have other testimony from various sources to confirm the fact of its absolute innocuousness.

PNEUMONIA MORTALITY OF PHYSICIANS.

It is generally supposed that physicians escape infectious diseases, notwithstanding their exposure, at least to an extent that is notable, considering the risks they run. There is some basis for this belief, for there is no doubt that they do largely escape in epidemics and in ordinary contagious disorders. This is owing to their better knowledge of the dangers and of how to ward off infection, as well as to a more intelligent and less panicky state of mind than is the case with the general public. When, however, a special malignancy is observed—as seems to have been the case the last few years with pneumonia, which is now acknowledged as an infectious disease—it is worth while to see how far the profession shares in the general mortality. We have looked up our records from October to March, inclusive, together with the first three weeks of April, to ascertain how many pneumonia deaths were reported among medical men. The pneumonia season just passed has had an average mortality of something like 15 to 20 per cent. of the total deaths during the season in some of the northern parts of the country. Taking the cases where the cause of death was known, we find that the percentage of deaths from pneumonia among physicians in October was 5; in November, 6.4; in December, 12.5; in January, 16.4; in February, 20.33; in March, 19.6, and for the first three weeks in April, 24. The figures probably do not cover all the cases, for a number are reported as having died after "short illness," which may indicate pneumonia. It would appear, therefore, that the medical profession has not escaped the increased mortality from pneumonia during the past pneumonia season. Considering the contingencies of their work, the exposures to cold, the wear of responsibility and the necessary irregularities of sleep, eating, etc., it is not at all wonderful that physicians should often succumb to pneumonia.

COMPARATIVE LONGEVITY.

The London *Lancet* calls attention to the fact of the large number of deaths occurring in well-to-do persons about the beginning of the seventh decade from diseases which are evidences of degeneration and premature senility, while other individuals pass on to the eighth and ninth decades in apparent health. It suggests that those who die thus early after the sixtieth year have indulged their appetites and lived unreasonably from a hygienic point of view. Considering that sixty years is a little beyond the average of human life and the numerous complications of heredity and incidental diseases, it seems that the position taken is a little too positive. People in prosperous circumstances that die at sixty have undoubtedly lived unhygienically in some respects, since no one lives according to the highest sanitary rules; their delinquencies may have been not the mere indulgences of their appetites, but the conditions through which, from the necessities of the case, they passed in order to attain their prosperous circumstances. We may put the average of human life as high as we please. There are few, however, who pass over the seventh decade, and still fewer who reach the ninth. That this has always been the case we have the best evidence in Holy Writ. Three score and ten is there given by the psalmist as the length of human life, except, when for reason of strength, it be four score. The nonagenarian was probably almost as rare in Moses' days as at the present time. In the strenuous life which we now live, with its many unhygienic accompaniments, among which we may include the strain and worry of modern civilization of which the ancients hardly knew anything, it is not remarkable that many fail before reaching their three score and ten. It is not fair to say that those who thus fail to do so have lived without restraint of their appetites. In some cases, at least, their appetites had to be restrained beyond reason, and the comparative degeneracy may be the later result of earlier innutrition.

THE TRANSMISSION OF BOVINE TUBERCULOSIS TO MAN.

In an interesting address[1] delivered before the Maryland Tuberculosis Exposition by Dr. J. George Adami, the title of which indicates a somewhat skeptical tendency of the author's thought on the subject of tuberculosis, the question of the communicability of bovine tuberculosis through the digestive tract of children is discussed. This is the method which Behring considers the chief or only one in its propagation. The test which Adami would recommend is based on the fact observed by Theobald Smith that the reaction of the bovine bacillus, as well as some of its other biologic characters, is somewhat different from that of the human germ, and that it takes some time for it to become so modified outside of its normal habitat as to assume that of the subject in which it is placed. According to Roux and Nocard, it requires months to convert human into avian types. It may well be that the bovine bacillus in the human system will require likewise an appreciable period for it to take on, so to speak, human characteristics. In acute cases in children the active development of the bacillus should occur, he thinks, before its ordinary features have become lost. If in our large centers some one or more workers were to make a continuous series of cultures from a long series of cases they might be able to solve the question as to the virulence of the bovine germ in the human subject, and the relative frequency of infection from the two sources would be determined. The test should be made under all conditions of exactness; the personal equation would be eliminated by the work of independent observers, and one of the disputed questions where high authorities differ would be in a way to be settled. Of course, we have reasonable evidence, as Adami says, that there is a certain danger from the bovine bacillus in the human subject, contrary to Koch's dicta, and no matter whether it is as serious as Behring states or not, it is a thing that ought to be carefully considered in our prophylaxis of tuberculosis. In the meantime, however, it will be well for us to obtain all the knowledge that is possible on the subject.

AUTOAGGLUTINATION OF THE ERYTHROCYTES.

There are many peculiar phenomena among the so-called immunity reactions. One of the most peculiar is the ability of an individual's serum to agglutinate his own corpuscles under certain conditions. This phenomenon has been observed in Hanot's hypertrophic cirrhosis of the liver by several observers (Klein, Hayem, Reitmann and Obermayer). It will be remembered also that Flexner considers autoagglutination of the red cells to be responsible for the thrombi which often form in typhoid fever, pneumonia, etc., the bacterial toxins possibly causing the agglutination. Eisenberg[1] has observed autoagglutination in a case of generalized pyocyaneus infection, arising from a severe wound of the leg. It had been noticed during the course of the infection that when blood was withdrawn for examination it did not clot in the ordinary manner, but the corpuscles gathered in clumps and sank to the bottom of the pipette, leaving clear plasma above. This is the phenomenon of autoagglutination. The serum from such blood was also isoagglutinating to some extent, that is, it would agglutinate the red cells of another individual. "At the autopsy the blood in all vessels, especially the cerebral vessels, appeared as a colorless fluid, in which heaps of coherent corpuscles were suspended in the form of red points." Blood obtained from the heart separated into a layer of agglutinated corpuscles at the bottom, while the serum collected at the top of the tube. Singularly, however, the serum had lost the isoagglutinating properties which it had during the patient's life. Eisenberg explains this by supposing that after death all the agglutinating substances had been absorbed by the patient's own corpuscles during their agglutination. This accords with the well-known fact that cells can absorb more agglutinin than is necessary to accomplish their agglutination. This observation raises a fundamental question. The patient's blood contained something which was capable of agglutinating his own corpuscles, yet this agglutination would occur only when the blood was withdrawn from the body or after the patient's death. This suggests in the first place the view of Metchnikoff, that the "immune bodies" exist for the most part intracellular in the body, i. e., in the leucocytes, and are liberated only when these cells disintegrate after blood is drawn or after the animal's death. It suggests also how vastly different processes in the test-tube may be from those in the living body. From observations of this nature, of which there are other examples, it is evident that there is much which is yet dark as to the *modus operandi* of the immunizing substances.

BLOOD IN THE FECES IN GASTRIC DIAGNOSIS.

As surgical knowledge advances and surgical skill becomes more perfect, the need for some early diagnostic sign in obscure stomach conditions becomes more and more apparent. Recently a number of articles have been published in Germany, which speak favorably of the value of traces of blood in the feces as a diagnostic sign in obscure cases of cancer and ulcer of the stomach. Schmilinsky's recent article[1] gives a good review of the subject. This author suggests that the examination of the feces it is to be noted that the color and the absence of general practitioner. The examination of the stomach juice is of value in some cases, but here the introduction of the stomach tube and the possibility of slight hemorrhage from this lead to a source of error. In examining the feces it is to be noted that the color and the absence of blood by microscopic tests are of no importance. Blood may be present in traces in fecal material of a light yellow color, and when it has passed all the way from the stomach it is no longer detectable by microscopic examination. Before making the test the patient should be prepared. He should avoid all raw or partly cooked meat, and should live on a diet of eggs, carbohydrates and fruits, though fruits containing much chlorophyl should be avoided. The test should not be made until the third day that the patient has been on such a diet. Severe purging should be avoided, though mild doses of castor oil may be given in order to be sure that a thorough evacuation of the whole intestinal tract takes place. After the proper preparation of the patient as described, the feces are collected for examination. Schmilinsky recommends Weber's modification of the guaiac test, which consists in extracting a mass of feces the size of a hickory nut with acetic acid followed by ether, and then testing the filtered ethereal extract. Old oil of turpentine or peroxid of hydrogen is added to the ethereal extract as an oxidizing agent, and in the presence of blood a blue color appears. The use of this method insures the reaction with blood alone, while the old method of direct testing was liable to many errors, as milk, potato, salts of iron, sputum or pus, and certain intestinal ferments could also give the reaction. The significance of a positive test for blood is discussed by Schmilinsky. He holds with Boas that a positive test is practically never found in normal individuals, in cases of atony of the stomach, in gastric neuroses, and in hyperchlorhydria and hypochlorhydria. Traces of blood in the feces are, on the other hand, very frequent in cases of gastric ulcer and carcinoma. The test is most important in cases of gastric carcinoma, where the tumor is not palpable, and there are no marked signs of pyloric obstruction. The blood test is, of course, not pathognomonic of carcinoma in cases of this kind, but its constant presence may be of great aid in establishing an early diagnosis.

THE YELLOW-FEVER SITUATION ON THE MEXICAN BORDER.

We recently had occasion to refer to the good work of the Public Health and Marine-Hospital Service in suppressing yellow fever in Texas last fall, and to the active prophylactic campaign now being carried on to prevent the recrudescence of the fever. From the amount and character of the work done by these officers, as shown by recent numbers of the weekly public-health reports, it is evident that the danger of an epidemic of yellow fever in southern Texas is being materially lessened daily. Although the last case declared to be yellow fever in Laredo was noted March 14, a complete house-to-house inspection of the entire city was made daily until April 18. This house-to-house inspection, in which the city was divided into thirty districts and each district inspected once every twenty-four hours, enabled the inspectors to discover and screen promptly all cases of fever, and thus eliminate the possibility of the development of new foci of the disease. Daily inspection also made possible more thorough and systematic oiling of water containers and other breeding places for mosquitoes. Allowing twelve days for the mosquito, after having bitten a yellow-fever patient during the first three days of his illness, to become infective, and five days for the period of incubation in an individual bitten by the mosquito, it may be assumed that secondary cases might develop in seventeen days. Of course, the mosquito remains infective after the twelfth day, and secondary cases may develop, therefore, long after the seventeenth day, but each daily house-to-house inspection after the seventeenth day which has developed no case of yellow fever increases the probability of safety. If, after the seventeen-day period had elapsed, a daily house-to-house inspection for six or seven days failed to discover any new case of yellow fever, the probability of any case of yellow fever existing would not be very great. On this theory is based the length of time the daily inspection of the entire city should be kept up. On April 18 this daily house-to-house inspection was discontinued, it being no longer deemed necessary to cover the entire city every day. The inspection force was reduced and the period required for inspecting the whole city with this reduced force necessarily extended from one to several days. The reduction of the inspection force in Laredo made available for immediate use in other localities a body of men trained and equipped for mosquito-destroying work. At Laredo the lines of possible infection diverge along the two railroad lines leading out of the city, the International and Great Northern Railroad running north to San Antonio and the National of Mexico running east to Corpus Christi. The San Antonio and Aransas

---

[1] Münchener med. Woch., Jahr. 50, No. 49; The Journal A. M. A., Jan. 16, 1904, p. 210.

Pass Railroad runs southeast from San Antonio to Corpus Christi, and, with the railroads mentioned above, completes, roughly speaking, a triangle which incloses the territory most likely to be infected now or to become infected in the future. The men made available by the amelioration of the conditions in Laredo have been employed in mosquito-destroying work in the towns along the railroads forming this triangle—from Laredo to San Antonio, from San Antonio to Corpus Christi, and from Laredo to Corpus Christi. Many of these towns are known to have been badly infected with yellow fever last fall and winter, and to prevent the possible recurrence of the disease required energetic treatment. Wherever possible, all habitations in these towns were fumigated for mosquitoes, and the inhabitants organized into citizens' leagues and instructed in the practical destruction of mosquitoes. Railroad officials have promised to have water-barrels, tanks, etc., along the railroad lines covered with a film of kerosene oil. This action will not only eliminate many possible breeding places for mosquitoes, but will also exercise an educational influence on the inhabitants. Doctor Richardson of the Service has prepared a practical circular on mosquito destruction, which has been printed in large numbers and distributed freely among the inhabitants of the towns within this triangular area.

Medical News.

ALABAMA.

Negroes Have Smallpox.—On April 25 six cases were reported to the health authorities of Montgomery, and the patients, who were all negroes, were removed to the isolation hospital.

Medical College Loses Suit.—The petition of the board of trustees of the Medical Department of the University of Alabama, Mobile, for a writ of mandamus to compel the payment of the first installment of the $20,000 appropriation voted by the legislature for that institution, but not approved by the governor, was denied by Judge Sayre of Montgomery, April 22.

Personal.—Dr. James H. Gunn, Calera, health officer of Shelby County, has been awarded $4,450 damages for injuries sustained by falling into a ditch left unprotected by a firm of contractors.——Dr. John McI. Whiteside, Anniston, has been elected health officer of Calhoun County.——Dr. William H. Sanders, Mobile, has been unanimously re-elected state health officer.

State Association Meeting.—The thirty-first annual meeting of the Medical Association of the State of Alabama was held in Mobile, April 19 to 22. The following officers were elected: Dr. Capers C. Jones, East Lake, president; Dr. Walter H. Bell, Hargrove, vice-president; Drs. Edward H. Sholl, Birmingham, and Isaac L. Watkins, Montgomery, censors, and Dr. Seale Harris, Union Springs, orator. Montgomery was selected as the place for the 1905 meeting. On April 21, the Mobile Medical Society entertained the state association at a banquet, which was attended by nearly 300.

ARKANSAS.

Personal.—Dr. Oscar E. Jones has been re-elected health officer of Newport, and chairman of the local board of health.

For Pure Food.—Pulaski County Medical Society has adopted resolutions unqualifiedly endorsing the Hepburn pure food bill.

Smallpox in Jonesboro.—Jonesboro has 10 cases of smallpox in its isolation hospital, and one patient quarantined in her house. Only one of the patients is white.

Nineteen Graduate.—Out of a class of 23 at the Medical Department of the University of Arkansas, only 4 failed to pass the required examination. A class of 19 was given diplomas by Dr. James A. Dibrell, dean of the faculty, April 8, at the annual commencement exercises. Rev. J. K. Smith, Little Rock, delivered the address of the evening.

CALIFORNIA.

New Practitioners.—Cooper Medical College, San Francisco, graduated a class of 44, April 26. Dr. Charles N. Ellinwood conferred the degrees and president Benjamin Ide Wheeler of the University of California delivered the address of the evening.

Society Election.—At the annual meeting of the San Diego County Medical Society, April 1, Dr. Peter J. Parker, San Diego, was elected president; Dr. Edward M. Fly, National City, vice-president, and Dr. Thomas L. Magee, San Diego, secretary and treasurer.

March Mortality.—During March 1,432 deaths were reported, equivalent to an annual death rate of 16.56 per 1,000. Tuberculosis caused 258 deaths; heart disease, 171, and pneumonia, 116. An increased percentage in the deaths from typhoid fever and tuberculosis was noted.

Oakland Hospital Dedicated.—Providence Hospital, Oakland, erected through the efforts of the Sisters of Providence, was dedicated with imposing ceremony April 5. The hospital is a four-story frame structure, with a separate heating plant, and will accommodate 150 patients.

State Society Meets.—The thirty-fourth annual meeting of the Medical Society of the State of California was held at Paso Robles, April 19 to 21. The election of officers resulted as follows: President, Dr. Frank L. Adams, Oakland; vice-presidents, Drs. William T. Lucas, Santa Maria, and Wesley W. Beckett, Los Angeles; secretary, Dr. Philip Mills Jones, San Francisco; assistant secretaries, Drs. Thomas C. McCleave, Berkeley, and William F. Barbat, San Francisco; board of examiners, Drs. Dudley Tait, San Francisco, Walter S. Thorne, San Francisco, John C. King, Banning, A. Lincoln Cothran, San Jose, and George F. Reinhardt, Berkeley; councilors, Drs. Ashley S. Parker, Riverside, H. Bert Ellis, Los Angeles, Thomas C. Edwards, Salinas, George A. Hare, Fresno, Jacob L. Asay, San Jose, Curtis G. Kenyon, San Francisco, Edward N. Ewer, Oakland, Thomas Ross, Sacramento, Arthur H. Mays, Sausalito, Frank B. Carpenter, San Francisco, and George H. Evans, San Francisco, and Fitch C. E. Mattison, Pasadena, and delegates to the American Medical Association, Drs. H. Bert Ellis, Los Angeles, and W. Le Moyne Wills, Los Angeles. Riverside was chosen as the next place of meeting.

COLORADO.

Staff Elects Officers.—At the recent meeting of the medical and surgical staff of St. Joseph's Hospital, Denver, the following officers and committees were appointed: Dr. Alfred R. Seebass, president; Dr. Frank E. Waxham, vice-president; Dr. Edward Delehanty, secretary; Drs. Leonard Freeman, Thomas J. Carlin, and W. Bedford Craig, executive committee, and Drs. Patrick V. Carlin, Charles B. Lyman, and James B. Devlin, training-school committee.

CONNECTICUT.

Measles.—During the last twelve months, 8,190 cases of measles were reported by the local health officers of the state.

Personal.—Dr. Leonard B. Almy, Norwich, is still seriously ill, but conditions seem to be more favorable for his recovery.——Dr. Joseph H. Townsend, New Haven, has been appointed major and surgeon, and assigned to the *Second Infantry*.

Yale Gets Legacy.—By the will of the late Mrs. Henry Farnam of New Haven, Yale Medical School receives a legacy of $54,500 to be applied to the general endowment fund of the institution.

Infectious Diseases.—In the month of March, infectious diseases were reported as follows: Measles, 844 cases in 57 localities; scarlet fever, 191 cases in 47 localities; diphtheria, 93 cases in 26 localities; pertussis, 55 cases in 11 localities; typhoid fever, 31 cases in 17 localities, and tuberculosis, 29 cases in 11 localities.

March Deaths.—During March 1,517 deaths were reported, equivalent to an annual mortality of 19.2 per 1,000. Deaths from infectious diseases were 353, or 23.2 per cent. of the total mortality. Pneumonia caused 235 deaths; consumption, 149; nervous diseases, 173; heart disease, 136; influenza, 120; violence, 75, and bronchitis, 60.

DISTRICT OF COLUMBIA.

Violations of Pure Food Law.—Seven dealers in milk were prosecuted last week for violation of the pure food law.

Personal.—Dr. John C. Simpson, second assistant physician at the Government Hospital for the Insane, has resigned, to take effect May 16.

Field Hospital at Washington Barracks.—A new field hospital has been erected at Washington Barracks, near the Navy Yard, under the supervision of Capt. Frederick P. Reynolds, of the medical department of the Army.

Health of the District.—The report of the health officer for the week ended April 30 shows the total number of deaths to have been 125, of which 74 were white and 51 colored. The number of births reported was 109, of which 76 were white and 33 colored. The close of the week there were under treatment 9 cases of diphtheria, 22 of scarlet fever and 51 of typhoid fever.

Reed Memorial Incorporated.—The certificate of incorporation of the Walter Reed Memorial Association has been filed for the purpose of securing funds to erect a monument in Washington City to the memory of the late Walter Reed, major and surgeon U. S. Army. The officers of the association are Daniel C. Gillman, president; ex-Surgeon-General George M. Sternberg, vice-president; General Calvin Dewitt, secretary, and C. J. Bell, treasurer.

Casualty Hospital Report.—The quarterly report of the Eastern Dispensary and Casualty Hospital shows the total number of patients received, 567; prescriptions compounded, 822; re-visits, 1,769; re-dressings, 1,435; operations, 29; emergency cases treated, 411, and operations performed, 115. The grounds now occupied by the hospital have been purchased for the new site of the senate office building. The hospital will consequently be obliged to move and rebuild in the near future.

ILLINOIS.

Shun Publicity.—Alton Medical Society, at its last meeting adopted a resolution asking the press not to mention the name of a practitioner attending an accident case.

Society Elects Officers.—Jo Daviess County Medical Society held its annual meeting at Elizabeth, April 28, and elected the following officers: President, Dr. Thomas J. Stafford, Stockton; Dr. Alvan F. Bucknam, Warren, vice-president; Dr. Domer G. Smith, Elizabeth, secretary and treasurer, and Dr. I. Carson Smith, Stockton, delegate to the Illinois State Medical Society.

An Irregular Wanted.—A reward of $200 has been offered for the arrest of "Dr." Peter R. Langdon, Kankakee, who is wanted by the authorities on the charge of performing a criminal operation, as a result of which Mrs. Charles Carr died April 16. It is said that the accused has been charged with practicing medicine without a license, and with other criminal offenses.

Chicago.

Hospital for Orphan Asylum.—Plans have been prepared for a fireproof hospital in connection with St. Joseph's Provident Orphan Asylum, to cost about $80,000. It will be a concrete, brick-faced, four-story building.

Deaths of the Week.—For the week ended April 30 the mortality was 561, or an annual death-rate of 15.17 per 1,000. Pneumonia still heads the list with 114 deaths, followed by consumption with 62, Bright's disease with 53, heart diseases with 45, and violence with 33.

Low April Death Rate.—The death rate for last month was, with three exceptions, the lowest on record. The 2,486 deaths reported during the month represent an annual death rate of 15.68 per 1,000. The great reduction, as compared with 1903, is in deaths of children under 5, and amounts to nearly 30 per cent.

Increased and Decreased Mortality.—For the first third of 1904 apoplexy deaths increased 22.6 per cent.; those from Bright's disease 16 per cent.; from cancer, 10 per cent.; from violence, 9.4 per cent.; from consumption, 9.1 per cent.; from heart diseases, 3.3 per cent.; and from pneumonia, 3.7. During the same period the percentages of decreased mortality were as follows: Influenza, 50; nervous diseases, 17.5; smallpox, 94; typhoid fever, 43.3, and suicide, 20.

Medical Officers Examined.—By order of Surgeon-General Senn, an examination of candidate medical officers for the National Guard was held at Rush Medical College, April 30. Eight candidates took the examination; of these five were for the naval reserve, two were dental surgeons, and one examination was promotional. The range of subjects included anatomy, physiology, chemistry, materia medica and therapeutics, pathology and bacteriology, hygiene and sanitation, military surgery and practice of medicine. The naval candidates were examined on naval hygiene and sanitation, and the dentists anatomy, physiology and dentistry.

MARYLAND.

Personal.—Dr. William Franklin Twigg, Cumberland, has been appointed physician to the county asylum and almshouse.——Drs. Charles F. Bevan and Thomas S. Latimer, Baltimore, have been appointed members of the State Lunacy Commission.——Dr. John W. Cooper, Jr., Elkton, has been made secretary of the Cecil County Board of Health.

Sanitary Officers.—The following have been appointed sanitary officers of Baltimore County: Second District, Dr. John E. Bolte, North Branch; Third District, Dr. Henry M. Naylor; Fourth District, Dr. H. Montrose Slade, Reisterstown; Fifth District, Dr. Benjamin F. Price, Mount Carmel; Sixth District, Dr. J. S. Baldwin, Freeland; Seventh, Dr. Thomas C. Baldwin, Gemmills; Eighth District, Dr. T. Ross Payne, Corbett; Ninth District, Dr. Richard C. Massenburg, Towson; Tenth District, Dr. Thomas H. Emory; Eleventh District, Dr. James F. H. Gorsuch, Fork; Twelfth District, Dr. Caleb M. Askey; Thirteenth, Dr. Frank H. Ruhl, Lansdowne; Fourteenth, Dr. William D. Corse, Gardenville, and Fifteenth, Dr. John W. Harrison, Middle River.

Baltimore.

Physician Robbed.—Dr. John Briscoe was held up and robbed of a diamond pin and money April 22.

Personal.—Dr. Thomas Sudler has been appointed coroner, and assumed his duties May 1.——Dr. Harry K. Gorsuch has been appointed health warden of the Fourth Ward, and Dr. George B. Scholl of the Sixteenth Ward.

Commencement.—The Baltimore University School of Medicine held its commencement April 19. The address was delivered by Senator Chauncey M. Depew of New York. There were 52 graduates. Dr. Joseph MacDonald, Jr., delivered the valedictory; Dr. Charles F. Willinsky of Massachusetts won the university prize, and other prizes were won by Drs. Lewis P. Knoll of New York; George W. Bell of New Jersey, and Charles L. Bates of West Virginia.

The Frick Collection.—The Charles Frick collection of the library of the Medical and Chirurgical Faculty of Maryland now numbers 2,500 volumes. The great majority of these are new works, and monographs in English, French and German. The section on the urine and diseases of the kidneys is particularly rich. A very important gift was made during the year by Dr. William Osler of 121 theses by American students at the University of Edinburgh between 1760 and 1810, a rare collection of Americana, which belonged to the library of the late Professor Hope of Edinburgh. The number of books borrowed for home use during the year was 1,683, and there were 4,351 readers in the library. The book-cases in the Frick room have become so crowded that it has been necessary to put shelves in the large meeting hall and place there part of this valuable collection. The Messrs. Frick have continued their annual appropriations.

MASSACHUSETTS.

Hospital for Brookline.—Fifteen physicians and surgeons of Boston have banded together and built a hospital on the north west slope of Corey Hill, Brookline. The building is of red brick and Indiana Sandstone, with very large allowance of air space for each of the twenty-five patients for whose care it is designed. It has special rooms for sun baths. The view from the top of this hill is unobstructed, and it is expected that this will in itself materially promote the convalescence of the patients. Miss Frances A. Stone, assistant superintendent of the Presbyterian Hospital of New York is to be the superintendent. All the details of the latest modern ideas of construction and equipment have been embodied in the structure. The physicians of the corporate membership will be given the preference in the use of the vacant beds, but other physicians will also be allowed to care for their patients there.

NEW JERSEY.

Spotted Fever.—Several cases of spotted or cerebrospinal fever have been located in Bordentown. The disease has also been carried from Bordentown to Trenton. Three deaths have resulted from the disease thus far.

Personal.—Dr. Harry H. Nelden has been elected first mayor of the new borough of Stanhope.——Dr. Charlotte Steckle, Trenton, has been appointed physician to the State Home for Girls.——Dr. Edward P. Buffett, Jersey City, has resigned as visiting surgeon to the City Hospital.——Dr. Elsmore Stites has been re-elected president, and Dr. John H. Moore, secretary of the Bridgeton Board of Health.

Smallpox in Lower Alloway.—Smallpox still continues in Lower Alloway, and so many cases have been reported that Dr. W. H. Husted, the health officer, has ordered all public schools closed and no public meetings of any kind held. Owing to the prevalence of the disease the board of health has ordered general vaccination of the residents of the community.

NEW YORK.

Albany College Commencement.—Albany Medical College graduated a class of 43, May 3.

Personal.—Dr. Charles H. North, Dannemora, has been made first assistant at the state hospital.——Dr. Henry Y. Grant, Buffalo, has returned from Europe.

Typhoid Decreases at Watertown.—The typhoid epidemic at Watertown is practically at an end. There have been reported 600 cases, with 44 deaths, since January 1, and there are 67 active cases at present.

Health Board Appointments.—Dr. E. F. Sheehan, president, Ossining; Dr. Wallace Clarke, health officer, Utica; Dr. Henry C. Sutton, health officer, Rome; Dr. Clarence C. Miles, health officer, Greenport; Dr. Charles G. Strobel, health officer, Dolgeville, and Dr. Harry S. Tuthill, health officer, Penn Yan.

Report of New York Institution for Instruction of the Deaf and Dumb.—In his annual report to the legislature, President Charles A. Stoddard stated that during the year there were 464 pupils, that the deafness of 204 was congenital, and that 93 lost their hearing before the age of two years. As to the cause of deafness, cerebrospinal meningitis was responsible for 36 cases, brain fever for 34 cases, scarlet fever for 30 cases, and measles for 18 cases.

New York City.

New Fordham Hospital.—The plans for this new hospital, which is to replace the present Fordham Hospital, have been filed. The estimated cost is $560,000.

"Dr." Conrad Again.—This man, who was recently arrested and tried on charge of producing abortion and released under $12,000 bail, has been re-arrested on another charge of the same nature.

Hospital Debt Reduced.—The annual report of the managers of St. Mark's Hospital show that during the past year 3,334 patients received treatment and 1,350 operations were performed. One mortgage of $5,000 has been paid off, and another reduced by $2,500.

New Quarters for Bellevue Internes.—The trustees of Bellevue Hospital have announced that the top floor of the old college building will be made into dormitories for internes. The parents of several of the successful candidates for vacancies on the staff have inquired into the reports regarding the unsanitary conditions of the dormitories, and have been assured that no repetition of past misfortunes need be feared.

Contagious Diseases.—There were reported to the Sanitary Bureau for the week ended April 23, 1,630 cases of measles, with 37 deaths; 391 cases of diphtheria, with 53 deaths; 436 cases of scarlet fever, with 32 deaths; 2 cases of smallpox; 83 cases of varicella; 381 of tuberculosis, and 202 deaths; 28 of typhoid fever, with 5 deaths, and 55 deaths from cerebrospinal meningitis. There were also 399 deaths from pneumonia.

Measles and Cerebrospinal Meningitis in Brooklyn.—Measles was never so prevalent in Brooklyn as at present. For several weeks, from 75 to 100 cases have been reported daily, and this does not include adults. Since January 1 there have been 36 cases of cerebrospinal meningitis, and 9 out of every 10 have died. The health department takes measures to prevent its spread, but is much hampered in its efforts owing to the rapid course of the disease.

Clinical School Faculty Changes.—The following changes and additions were made, April 9, in the faculty of the New York School of Clinical Medicine: Dr. John L. Adams, elected secretary; Dr. Emmet C. Dent, professor of mental diseases; Dr. W. Brewster Clark, professor of internal medicine; Dr. Robert C. Kemp, professor, and Dr. Graham Rogers, associate professor of gastrointestinal diseases; Dr. Alfred W. Gardner, professor of hydro-therapeutics; Dr. George A. Taylor, professor, and Dr. William E. West, assistant and clinical instructor in ophthalmology and otology; Dr. C. Stern, chief of clinic and associate professor of genito-urinary diseases, and Dr. Leopold D. Weiss, chief of clinic and instructor in dermatology.

Real Estate Agents and "Race Suicide."—Careful investigation has demonstrated that, as a rule, New York landlords have a decided prejudice against children. A large number of real estate agents refused to rent to families having more than two children, and indicated plainly that even these were not desired. In one apartment house containing 60 families there were only 5 children; in another having 40 families, there were only 6 children, and in still another, only 1 child to 35 families. In 22 apartment houses, containing in all 485 families, there were only 54 children. These were high-priced apartments, but a similar condition was found to obtain in the less expensive flat houses. If families generally were not small, landlords could not enforce such rules without losing their rent.

Quarterly Report of Deaths.—The actual number of deaths for the last quarter of 1903 was 16,405, which, on an estimated population of 3,732,903, gave an annual death rate of 17.45 per 1,000, as against an average number of 15,480 deaths for the corresponding quarter of the preceding five years, which on an estimated population of 3,448,567, gave an annual death rate of 17.82 per thousand, a decrease of one-third of one per cent. The noteworthy increases found in comparing the deaths in this quarter with the preceding quinquennial average of the corresponding quarters were among the diseases affecting adults and old people as follows: apoplexy, 77; organic heart disease, 105; pneumonia, 426; Bright's disease and nephritis, 102, and pulmonary tuberculosis, 96. There were 782 more deaths between the ages of 5 and 65, and 270 more at 65 and over. Diphtheria showed an increase of 50, and measles 12 above the quinquennial average. The chief decreases noted were in whooping cough, acute bronchitis, malarial fever, and typhoid fever.

Immunization in Diphtheria.—A circular to physicians setting forth the importance of immunization for the prevention of diphtheria has been issued by the health department. It has been the custom of the department when administering antitoxin in cases of diphtheria, to give immunizing doses to other members of the family. The records of the department compiled from the reports of results show the great value of immunization. From Jan. 1, 1895, to Jan. 1, 1903, immunizing injections were administered to over 13,000 individuals, and, of these, only 3 per cent. contracted diphtheria of a mild type and only 1 case terminated fatally. The records show that during one year alone, 682 cases of diphtheria occurred in this city which were secondary to an original case in the same family. Of these 682 cases 61 died, a mortality of 8.9 per cent. Had these 682 individuals received the immunizing dose of antitoxin when the physician first visited the family, probably not one would have contracted the disease. The above figures represent only a fraction of such secondary cases occurring in New York City. The minimum dose of antitoxin to be used for immunizing a child under two years of age is 300 units; for older children and adults, 500 units.

Boil the Oysters.—At the last meeting of the county society, April 25, the oyster as a medium for transmitting the typhoid fever germ was discussed. Dr. Cyrus W. Field, assistant bacteriologist to the department of health, related the experiments conducted with typhoid-infected oysters and proved that oysters carried typhoid bacilli alive for nine days when in brackish water. Many oysters die in transit, and it was stated that dead and dying oysters furnished good culture media for these bacilli. It was shown that the oyster beds in the vicinity of the city were polluted and that typhoid germs might easily be present for transmission. The oystermen, aroused by Dr. Field's report on typhoid bacilli among oysters fattened in contaminated streams, offered $10,000 for the discovery of typhoid germs in oysters. Dr. Field said he would not claim the reward, because he had not found the germs in oysters, but that he knew that typhoid bacilli had been introduced into "drinking beds," and had found traces of them in oysters afterward. So much attention had been called forth by this subject that the English foreign office had sent a commission over to confer with our government on the conditions surrounding the cultivation of oysters sent abroad.

OHIO.

Cincinnati Internes Appointed.—Dr. Fannie Hollingshead of the graduating class of the Miami Medical College, was elected interne to Christ's Hospital after competitive examination.——At a recent meeting of the staff of St. Mary's Hospital, Dr. John H. Landis was elected to the department of medicine, and Dr. Park Gilmore to the department of pathology and microscopy. Drs. Carroll W. DeCourcey and S. U. Swing, both from the graduating class of the Medical College of Ohio, were elected internes for the ensuing year.

OREGON.

New Medical Building.—Willamette University, Salem, is about to erect a new building for its medical department, to cost $10,000.

Personal.—Dr. Robert J. Pilkington has been re-elected city physician of Astoria.——Dr. Eugene Du Gas, Roseburg, has resigned his position as health officer of Douglas County.

Injured Physician Amputates His Own Leg.—The *Oregonian* reports that Dr. G. W. Maston, Klamath Falls, sustained serious injuries to his leg, April 20, which caught in the wheel of his buggy. Before assistance arrived, Dr. Maston had almost completed the amputation of his leg, with a penknife.

Seventeen Graduate.—On April 18, the medical department of the University of the State of Oregon, Portland, graduated a class of 17. The annual address was delivered by W. W. Cotton, Esq., and Hon. Charles B. Bellinger conferred the degrees. The charge to the class was delivered by Dr. Holt S. Wilson.

PENNSYLVANIA.

Personal.—Drs. Simon Seegman and Thomas F. Moore, assistant city physicians of Pittsburg, have resigned, and after a post-graduate course in Philadelphia, will study in Europe.——Dr. John A. Fall has been re-appointed a member of the Doylestown Board of Health.

Milk Inspection for Norristown.—The Montgomery County Medical Society has appointed a committee consisting of Drs. Joseph K. Weaver, S. Nelson Wiley and Reinoehl Knipe, to cooperate with the Norristown Board of Health to secure a purer and cleaner milk supply. Inspection is to be made of all dairies supplying milk to the borough.

War on Illegal and Malpractitioners.—At the last meeting of the Philadelphia County Medical Society resolutions were adopted and committees were appointed to apprehend and bring to justice the illegal and malpractitioners who are actively infesting Philadelphia. Dr. Henry Beates, president of the State Board of Medical Examiners, stated that there were 100 men practicing medicine in the city who had not passed the required examinations. A fund of $1,000 is being raised to prosecute these offenders. The work of ferreting out these individuals will be under the supervision of the censors and directors of the society. Another committee was appointed to offer the organized services of the society to the health authorities in their efforts to rid the city of malpractitioners and abortionists. This committee will endeavor to trap the malpractitioners and to locate licensed physicians who do illegal work. A blacklist of the latter men will be kept by the society.——At a meeting of the Northern Branch of the County Medical Society it was stated that 5,000 criminal operations are performed in Philadelphia every year.

Philadelphia.

Sherrington in Philadelphia.—Dr. Charles S. Sherrington, of the University of Liverpool, England, was the guest of the University of Pennsylvania, May 5, and delivered a lecture at the Medical School on "Cerebral Localization."

Medical Student Dies.—Samuel S. Stryker, son of Dr. S. S. Stryker, a junior in the University of Pennsylvania Medical Department, died at the Presbyterian Hospital, Philadelphia, after an operation for appendicitis, April 12.

Personal.—Dr. John M. Macfarlane, professor of botany in the University of Pennsylvania, sailed for Europe, April 30. He has four months leave of absence, and will do research work in the botanical gardens of London, Richmond, Florence, Geneva and Amsterdam.——Dr. Harry K. Carey sailed for Europe, April 30, and will be absent several months.

Tuberculosis Pavilions Ready.—The six tuberculosis pavilions at the Philadelphia Hospital for the treatment of patients with tuberculosis have been completed. During the past week they have been prepared, furnished, and are now practically ready for occupancy. The buildings are constructed entirely of steel and glass, and are so arranged as to give the patients every benefit of the out-door or open-air treatment of the disease. About 20 patients can be accommodated in each pavilion.

Entertain Societies.—Dr. J. William White, professor of surgery in the University of Pennsylvania, and Dr. Edward Martin, his colleague, entertained the Agnew Surgical Society of the university at Dr. Martin's country place, Yearnwold. The Agnew Surgical Society was formed during the time of Dr. D. Hayes Agnew. It has been the annual custom of Dr. White and Dr. Martin to entertain the Agnew Society at Yearnwold.——Dr. James Tyson, professor of medicine in the University of Pennsylvania, entertained the Tyson Society of the university at his residence, April 29.

Spotted Fever At League Island.—Four cases of spotted fever have been discovered among the sailors at the League Island Navy Yard. One of the victims died in the Naval Hospital; the other patients affected are in an isolated part of the navy yard. The sailors, about 1,000 in number, who have been housed in the barracks, are now camping out in tents. Strict quarantine has been placed on the grounds, and no one is allowed to come or go until the disease is checked. The entire camp is to be fumigated. Dr. Presley M. Rixey, surgeon general of the Navy has visited the yard and outlined plans to overcome the condition.

Health Report.—There has been a material decrease in the number of typhoid cases during the week ended April 30. There were 298 cases reported, as compared with 352 for the preceding 7 days. The number of deaths recorded, however, was high, 45. This was an increase of 31 over those reported during the previous week. There was also a decrease in smallpox, both in the number of new cases returned and in the deaths from that disease. The number of cases reported were 23, a decrease of 9 over the preceding week. The deaths from all causes during the week numbered 592. This is an increase of 3 over last week, and an increase of 93 over the corresponding period of last year. The deaths from pneumonia still continue unusually high. The total number of deaths attributed to this condition reached 82.

SOUTH CAROLINA.

Personal.—Dr. Benjamin W. Taylor, Columbia, has been recommissioned by the governor as a member of the board of regents of the Hospital for the Insane.

Commencement.—At the seventy-fifth annual commencement exercises of the Medical College of the State of South Carolina, Charleston, April 4, diplomas were given to twenty-three graduates in medicine. Governor D. Clinch Hayward delivered the address to the class.

Society's Semi-Centennial.—The Columbia Medical Society celebrated its fiftieth anniversary by a banquet, March 13. Dr. Lawrence B. Owens was toastmaster, and the past, present and future of the society were discussed, and informal and reminiscent speeches were made by the various members.

State Society Elects Officers.—At the fifty-sixth annual meeting of the South Carolina Medical Association, held in Darlington, April 19 to 21, the following officers were elected: President, Dr. Robert Wilson, Charleston; vice-presidents, Drs. William C. Black, Greenville, James H. McIntosh, Columbia, and Edward L. Patterson, Barnwell; secretary, Dr. T. Prioleau Whaley, Charleston, and treasurer, Dr. Charles P. Aimar, Jr., Charleston.

Nominates Medical Examiners.—The South Carolina Medical Association, on April 21, nominated the following as members of the State Board of Medical Examiners: First District, Dr. Walter P. Porcher, Charleston; Second District, Dr. Theodore G. Croft, Aiken; Third District, Dr. Orland B. Meyer, Newberry; Fourth District, Dr. Davis Furman, Greenville; Fifth District, Dr. R. Andral Bratton, Yorkville; Sixth District, Dr. James L. Napier, Blenheim; Seventh District; Dr. Samuel C. Baker, Sumter, and at large, Dr. William M. Lester, Columbia.

UTAH.

Must Register Deaths.—A circular has been sent by the State Board of Health to the boards of county commissioners, in which the board gives notice of its intention strictly to enforce the registration of deaths.

Must Report Tuberculosis.—The State Board of Health has adopted a rule which provides that physicians must report to the health officers all cases of tuberculosis. The board also announces that microscopic examination of sputum will be made free of charge at the state laboratory.

Refuse Vaccination—Smallpox Rife.—On April 23 there were at least 50 cases of smallpox at the quarantine hospital and under guard in Salt Lake City. The health commissioner attributes the spread of the disease to the refusal of the people to be vaccinated, and urges the adoption of more stringent regulations.

New Hospital for Salt Lake City.—Early in August the hospital endowed by the late Dr. W. H. Groves, and known as the Dr. W. H. Groves Latter-Day Saints' Hospital, will be ready to receive patients. About $117,000 will have been expended on the building and land at the time of opening. The building is four stories in height, and is fireproof throughout.

WASHINGTON.

Railway Hospital for Tacoma.—Plans have been completed for the erection of a hospital for the Northern Pacific Beneficial Association at Tacoma, to cost $100,000.

Six Weeks Quarantine Ordained.—The Seattle Board of Health has promulgated a rule to govern the handling of scarlet fever cases, which provides that hereafter, scarlet fever patients must undergo a minimum quarantine of six weeks.

Violence Heads Death List.—The death-causes of the year 1903 in the state show that 484 died violent deaths, and this does not include homicides; 446 died from tuberculosis; 283 from pneumonia; 236 from heart diseases; 181 from typhoid fever; 180 from senile debility, and 176 from kidney diseases. Of the 484 violent deaths 268 occurred in King and Pierce counties.

Personal.—Dr. William B. Wells has added to the staff of the Hoquiam General Hospital, Drs. Harry C. Watkins, Cosmopolis, and Dr. Horace Campbell.——It is announced that Dr. Edmond Klamke, Ilwaco, has been appointed to a position in the hospital service of the Russian army and has started for the seat of war.——Drs. Myra L. Everly, Harriet J. Clark, Park W. Willis, F. L. Horsfall and Robert M. Stith have been named as the medical staff of the Florence Crittenton Home, Seattle.

WEST VIRGINIA.

Bequests to Hospital.—The late Aaron Bloch, Wheeling, by his will bequeathed $5,000 to the permanent fund of the City Hospital.——The late Henry Jacobs bequeathed $100 to the same institution.

Construction Camps Under Guard.—Dr. Thomas H. West, health officer of Keyser, W. Va., has ordered two Wabash construction camps, containing 250 men, into direct quarantine on account of smallpox.

New Hospital Opened.—The New Cook Hospital at Fairmont was opened, April 29. It cost $100,000, and has 90 rooms. The walls and floor are constructed of white tiling, and there are marble stairways. There is a roof garden; also a sun parlor. The former hospital building will be used as a nurses' home. The hospital staff consists of Drs. John R. Cook, Albert W. Sterling, Edward W. Howard, Hal Hall, James J. Durrett and Dorsey P. Fitch.

GENERAL.

The American Proctologic Society will hold its sixth annual meeting at the Seaside House, Atlantic City, June 8 and 9.

Measles Among Canadian Indians.—The epidemic of measles which has been so fatal among the Indians of the Mackenzie Basin, Canadian Northwest Territories, is subsiding from lack of further material; scores have died.

Second Health Conference Called.—Surgeon-General Wyman of the U. S. Public Health and Marine-Hospital Service has issued a call for the second annual conference of state boards of health at the New Willard Hotel, Washington, June 3.

The American Confederation of Reciprocating Examining and Licensing Medical Boards will hold a meeting at the Great Northern Hotel, Chicago, May 24. At the present time the following states are reciprocating: Illinois, Kentucky, New Jersey, Maine, Maryland, Indiana, Nebraska, Ohio, Wisconsin, Iowa and Michigan.

Mexico is Quarantined.—To guard against yellow fever, Texas has established a quarantine against all persons coming from points in Mexico at which yellow fever existed last year. The Mexican authorities protest against the action of Dr. George R. Tabor, the state health officer of Texas, and have appealed to the Department of State.

Smallpox in Mexico.—A total of 318 deaths out of 500 cases of smallpox is the summary of the situation at Torreon, Mexico. The population of the city is 25,000, including 2,000 foreigners. Among the latter 20 cases occurred with 10 deaths. A number of physicians from other cities have assisted in the inspecting, the vaccinations and the burning of infected houses. The normal aspect of the city will be resumed, it is thought, in a few weeks.

Gen. Leonard Wood on Swimming.—Gen. Leonard Wood, in command of the military forces in the Philippines, has issued a general order calling attention of the company commanders to frequent cases of drowning among officers and men who have never learned to swim. He says:

> Definite arrangements should be made at every station at the seaside or near lakes or streams suitable for swimming, so that all can be taught to swim. This necessary and healthful practice should be encouraged and, if necessary, made compulsory.

Uncinariasis in Porto Rico.—The commission to investigate the causes of anemia in Porto Rico, consisting of Dr. Bailey K. Ashford, assistant surgeon, U. S. Army; Dr. W. W. King, assistant surgeon U. S. Public Health and Marine-Hospital Service, and Dr. Pedro Gutierrez, a native physician, report that 63 per cent. of the population is engaged in agriculture, that anemia is the apparent cause of 25 per cent. of all deaths, and that uncinariasis is the disease responsible. Measures for prophylaxis and treatment will be recommended.

To Fill Positions in the Philippines.—Examinations will be held at Baltimore, June 1 and 2, by the U. S. Civil Service Commission for the following positions in the Bureau of Government Laboratories at Manila, P. I.: Pathologist, $1,800; pharmacologist, $1,800; chemist, analytical division, soils and waters, $1,600; chemist, economic products division, familiar with organic chemistry, essential oils,, etc., $1,600; chemist and collector, economic products division, $1,500; assistant for physical chemist, $1,500; entomologist, $1,400; bacteriologist of serum division, $1,400. These represent the lowest salaries, but there are to be promotions and larger salaries in prospect.

CANADA.

New By-Law on Vital Statistics for Montreal.—The city council of Montreal has adopted a by-law requiring physicians and other qualified persons to report all births to the board of health within eight days. There has been in vogue in Montreal a system of reporting births, but it was considered most imperfect, and hence the new by-law.

St. John, N. B., Hospital Report.—Dr. T. H. Lunney, superintendent of the St. John, N. B., General Hospital, reports that 982 patients were treated there in 1903. There were 379 medical diseases, 489 surgical cases and 114 eye and ear cases; 498 patients were discharged cured, 307 as improved; 75 died and 49 remained. The out-door department totaled 640 cases.

Western Hospital, Montreal, Needs Addition.—The Western Hospital, Montreal, needs a new wing, and at a meeting of the board of governors last week, it was decided to open subscription lists at once for securing the necessary funds. The medical report for the quarter ending March 31, submitted by Dr. England, shows that 133 patients were admitted, 61 males and 72 females; 7 died and 29 are still inmates. The record of the out-door department brings the total consultations up to 1,783, which shows a decrease from the corresponding quarter of 219.

A Methodist Hospital for Toronto.—The leading Methodist church paper in Toronto advocates a Methodist hospital in Toronto, and judging from the manner in which all of the hospitals were congested during the past winter, there is ample room for such an institution. By the will of the late Hart A. Massey, $100,000 is available for the purpose, on condition that a similar amount should be subscribed. It is understood that the medical faculty of Toronto University would welcome such an institution within easy reach of their new medical building.

Kentville Sanitarium, New Brunswick.—The government of New Brunswick has about completed a sanitarium for consumptives at Kentville. It has been beautifully arranged and well fitted for the reception of patients, and will be opened without further delay. The building is situated on the north side of the Cornwallis River, with a magnificent southern exposure. The ground floor consists of a hallway, running through the whole length of the building, dining room, nurses' rooms, physicians' rooms, operating room, laboratories, etc., while upstairs there are twelve large rooms for patients.

A Protest.—The medical students of the province of Quebec are protesting against the proposed action of the legislature, which would throw open the doors of the profession in that province to those who have not fulfilled the conditions imposed by the present law. The bill now before the legislature proposes to admit all who have begun the study of medicine before September last, thus avoiding their matriculation examinations. The profession in Montreal is aroused against the measure and is sending a deputation to Quebec to protest before the legislature. The passage of the measure would benefit nearly 260 students in Quebec and Montreal.

Personal.—Dr. H. S. Hutchinson has been appointed assistant in the chemical laboratory, and Dr. F. W. Marlowe, assistant demonstrator in anatomy, at Toronto University.——The following appointments have been made at Queen's University, Kingston: To be professor of pediatrics and associate professor of obstetrics and gynecology, Dr. Wood; to be assistant professor of anatomy, Dr. Mylkes; to be professor of medical jurisprudence and toxicology, Dr. Williamson.——Dr. Frederick Etherington, Kingston, Ont., has been appointed to the newly inaugurated tutorship in human and comparative anatomy at Queen's University. Dr. Etherington is now in Edinburgh, Scotland, further pursuing medical studies, but will return in the autumn.——Dr. George Wilkins, professor of medical jurisprudence at McGill University, at the termination of his course of lectures for the 1903-1904 session, was presented by his class students with a handsome illuminated address inscribed in Chinese characters.——Dr. J. H. Wilson, St. Thomas, who for many years sat in the Canadian House of Commons, has been appointed a senator by the dominion government, succeeding Dr. Geo. Landerkin, deceased. The medical profession of the county of Elgin, Ontario, tendered Dr. Wilson a banquet April 11.——Dr. L. Harwood, Montreal, has been appointed professor of gynecology in Laval University and chief of the gynecologic department of Notre Dame Hospital of that city, succeeding the late Dr. Brennan. He has also been chosen president of the section on gynecology of the Medical Congress of French-Speaking Physicians of North America, which is to meet in Montreal this year.

FOREIGN.

Bubonic plague continues on the west coast of South America.

King Edward VII Hospital in Grosvenor Garden, London, has been opened for the treatment of sick officers of the British army. Thirty London practitioners of eminence are on the staff.

Historical Medical Museum.—The formal opening of the department of medical history in the Germanic National Museum at Nuremberg occurred recently. All over Germany and Austria families have been delving among their heirlooms from medical ancestors and have found many articles of surpassing historical interest, which have been presented to the museum. The collection of books and MSS., instruments and medals is being rapidly catalogued. Those in charge regard the work as a memorial to Dr. R. Landau, who gave the first impetus to the project.

The Paris "Societe de l'Internat."—A new society has been organized at Paris to unite the past or present internes of the hospitals in fraternal bonds. The first meeting was held February 7, 1904, and the membership has already reached 140. Meetings will be held at 5 p. m. the fourth Thursday of each month in the rooms of the surgical society. The presidency has been conferred on Professor Jacquet; Berthod is vice-president, and Marcel Baudouin has charge of the archives. The first scientific meeting will be addressed by Widal on the subject of "Dechloridation, Its Indications and Therapeutic Results."

Remote Results of an Advertised Eye Remedy.—Professor Siegrist, the well-known ophthalmologist of Berne, has had occasion to examine later the eyes of persons who have been advertised as cured by ophthalmol, an oil claimed to cure all eye affections. One subject was a man of 65, who exhibited a whole battery of empty bottles of the oil and had been heralded by the manufacturer of the oil as a brilliant example of its success. He was found a year later to have bilateral cataract, which had ripened during the interval. Siegrist publishes in the *Aerztl. Vereinsblatt* a number of other cases in which he has had to perform cataract extraction on patients alleged to have been cured by the oil. It is derived from certain fish, and a stock company has been formed to exploit it, with the intention to open "eye parlors" in sixteen German cities.

Leipsic Number of the Deutsche Medicinische Wochenschrift.—The German Congress for Internal Medicine was held at Leipsic, April 18 to 21. In honor of this event the *Deutsche medicinische Wochenschrift*, whose publishing house is in Leipsic, issued a festival number. It is entirely devoted to articles issuing from the Leipsic clinics—a total of twelve important works, headed by Curschmann's monograph on "Unusual Course and Sudden Death in Typhoid." The photographs of leading physicians in charge of the internal medicine clinics in Germany, Austria and Switzerland are grouped on a separate sheet—thirty-three in all, with Bäumler, Curschmann and von Leyden in the center. The portraits are all strikingly good and well printed, the sheet about 10x12 inches, framing well.

Tuberculosis in German Prisons.—Dr. Bär, an experienced German prison medical officer and medical statistician, has recently made an appeal for the temporary paroling of tuberculous prisoners or their detention in special hospitals. He urges the necessity for some such measure from the statistics of the death rate from tuberculosis in the prisons during the last fourteen years, which was 56 per cent. of the total mortality from natural causes. Even in the most hygienically equipped prisons the mortality could not be reduced below 38.3, while the average in the populace outside is only 18.5 per cent. Convicts who are already tuberculous on their entrance prove a dangerous source of infection for others, and they should be kept apart in separate quarters or temporarily transferred to some hospital. Estimates for a tuberculosis hospital or sanatorium pavilion in each prison are now being prepared, and Bär's suggestion will probably be acted on when the appropriations are made for another year.

Physician Fined for Error of Druggist.—The local court of Havre, France, has recently imposed a fine of $40 and costs on a local physician. The physician and druggist were sued for damages in a case of homicide from imprudence. A child had been injected with a solution of cocain 1/50 instead of 1/500, which the physician had ordered to be put up. The court decided that the physician had been remiss in not verifying the strength of the solution when it was delivered to him; also in having the syringe filled by an ordinary nurse instead of a trained assistant. He was considered the only one responsible. The prescription could not be found and the pharmacist was acquitted. This case, by the way, is cited by a writer in an English exchange to show the danger of error in reading prescriptions dosed according to the metric system: "It is so easy to misplace or misread the decimal point, while the hieroglyphics at present in use afford less occasion for error."

Danger of Self-Medication in Incipient Tuberculosis.—The French Antituberculosis League, which conducts the special tuberculosis dispensaries in France, has found that out of the 70,000 consultations given to tuberculous subjects during the three years of its establishment, only a very few patients were seen at the commencement of their lung affection. The overwhelming majority were in too advanced a stage for medical aid to be effective. The league has also discovered that this majority had wasted months or years after the first symptoms of illness had been noticed, in self-medication, taking this or that advertised remedy until the precious opportunity for cure had passed. Resolutions were, therefore, adopted calling this fact to the attention of the authorities, warning that the sale of these nostrums "warranted to cure coughs, colds and tuberculosis" is the cause of many unnecessary deaths every year, and should be indicted on the grounds of the illegal practice of medicine, deliberate fraud and murderous practices.

The German Medical Exhibit at the World's Fair.—The committee in charge of the exhibit decided to devote the comparatively small space allotted to Germany to a presentation of the German methods of instruction in medicine. Anatomy, surgery, internal medicine and bacteriology are thus presented in systematic order, as taught in Germany. One-fourth of the entire space is given up to bacteriology and experimental therapy, outlining a complete course, with each of the most important human and veterinary diseases treated separately. The etiology is shown by cultures and pictures of the germs, their pathogenic properties by mounted specimens and plates, and differentiation by production of agglutination and the specific chemical changes in the micro-organisms. The various procedures in bacteriologic examination are also presented, and a complete outfit of one of the "flying laboratories" organized to fight typhoid and other epidemics on the spot. The principle is to fight the disease in the individual and destroy all infection breeders on the spot. There will be ample evidence, pamphlets, statistics, etc., to testify to the value of this mode of prophylaxis of epidemics. The exhibit of serums, their standardization and their practical results is the co-operative display of the Imperial Board of Health, the Institutes for Infectious Diseases at Berlin and for Experimental Therapy at Frankfurt, the institutes at Halle and Breslau and Dunbar's institute at Hamburg besides the private firms that manufacture serums. The exhibit for internal medicine portrays a clinical lecture on the subject of tuberculosis, etiology, examination of patient, pathologic findings, prophylaxis and treatment. The surgery exhibit is planned on much the same lines, but comprises two separate displays, one arranged by von Bergmann, the other by Mikulicz, each exhibiting the instruments, etc., preferred. Bergmann presents a portable Röntgen apparatus which allows reduction and fixation of fractures, etc., under constant control of the eye. Nitze's first, original cystoscope is seen in this display. Great efforts have been made to make the exhibit of pathologic anatomy truly representative of German achievements in this line with actual specimens preserved in the Kayserling fluid, casts, photographs, atlases, etc., contributed by many institutions and clinicians.

LONDON LETTER.

Recrudescence of Smallpox in London.

The usual seasonal rise in smallpox has taken place; 17 fresh cases were reported in January, 19 in February and 108 in March. In the fortnight ending April 9 there were 61 more cases. These figures refer only to notifications; some of the cases proved not to be smallpox. The cases have occurred chiefly in the poorest part of the metropolis—the east end. As in the recent epidemic, the spread of the disease is largely due to unrecognized cases. Early removal to hospital, disinfection and supervision and revaccination of "contacts" are being energetically carried out.

The Reorganization of the War Office and of the Army Medical Service.

The war office can be relied on to do two things—to shamefully muddle military affairs and to "sit on" the medical profession whenever the opportunity occurs. The glaring military incapacity disclosed by the South African war led to the appointment of Lord Esher's committee, which has made sweeping changes in the war office. The office of commander-in-chief has been abolished and his authority divided between the members of the new army council, each responsible for a department, such as inspection of troops, fortifications, commissariat, etc., but no place has been found for the army medical service on the council. Hence fierce criticism of this grave defect appears in the medical press. Only weak and inefficient replies are forthcoming. It is said that the adjutant general, a member of the council, occupies a much stronger position than his predecessor, and will be able to represent effectively the medical needs of the army. But no answer is vouchsafed to the obvious reply to this. How can he possibly, with his extensive and multifarious duties, to say nothing of his ignorance of medical matters, represent them as well as the director of the army medical department? The naval and military committee of the British Medical Association has passed a resolution to the effect that the medical service of the army occupies so important a position in safeguarding the health and life of the soldier in peace and war that it is essential in the best interests of the army that the medical service shall be administered by a medical officer, with a seat on the army council.

The Society for the Study of Inebriety.

At the annual meeting of the Society for the Study of Inebriety, Dr. Harry Campbell, the president, said that the past year was the most successsful the society has ever had, its membership having increased by leaps and bounds. The twentieth annual report, which was adopted, showed that during the year 117 doctors have been elected members and 152 lay associates have joined. The number of associates and members now reaches 400. The council has arranged for the publication quarterly of the *British Journal of Inebriety*, of which four numbers have appeared. After the formal business had been transacted Dr. Robert Jones, medical superintendent of the London County Asylum, read an important paper on "The Relation of Inebriety to Mental Disease." He stated that although the improvement which occurred under treatment in alcoholic insanity was often noticed it rarely ended in complete recovery, as a relapse often occurred after discharge from the asylum. When in cases of alcoholic indulgence the moral sense became perverted, no appeal to reason was of avail, and ordinary motives were inadequate to save the victim from the domination of the drink craving. At the London Asylum, Claybury, there were admitted during 1893-1903, inclusive, 9,544 persons, of whom 1,664 (965 males and 699 females) owed their insanity to drink. There are over 400 persons in retreats and reformatories for inebriety, and these represent only a small proportion of the inebriates of the country whose presence among the young is most injurious. Dr. Jones's experience of the treatment of drunkards in asylums is disappointing. When the patients are discharged they almost invariably relapse if they taste alcohol at all, and only a few afterward go through life without it.

Tramps and Smallpox.

Dr. H. E. Armstrong, health officer for Newcastle-on-Tyne, has issued a valuable report showing the great part played by tramps in the propagation of smallpox. As the result of an exhaustive inquiry made ten years ago he found that the disease was first introduced by vagrants into 58 per cent. of the 63 large towns from which returns were received, and was introduced by the same agents into 72 per cent. of these again and again, on an average about 5 times into each. As a result of the publication of these figures the London County Council convened a meeting of sanitary authorities, which passed a number of resolutions. These were communicated to the local government board, but nothing whatever was done. Early in the present year Dr. Armstrong addressed a circular containing ten questions to the health officers of 205 provincial cities, boroughs, and urban districts, with populations of 20,000 and upwards. Replies were received from 125, and they confirm entirely the results of the previous investigation. Of the districts making returns 141 have been visited by smallpox during the recent outbreak, and to 51 per cent. the disease was first conveyed by tramps. Further it was reintroduced at least 305 times by vagrants into 58 places, where it had previously appeared. It was carried 23 times to Sheffield in this manner, 24 times to Manchester, 31 times to Wakefield, and 34 times to Liverpool. An object lesson has recently been furnished from Cardiff. A tramp was admitted to the workhouse who had probably contracted the disease in a lodging house in Matlock. He had stayed subsequently at Chepstow and Newport workhouses. Most of the other occupants of the tramp ward were revaccinated, but a few refused. There are now several cases in the Cardiff isolation hospital. The health officer urges the necessity of parliament passing a bill compelling all tramps who can not produce evidence of recent vaccination to subject themselves to the process. But with the exaggerated ideas of the liberty of the subject for which this country is notorious and the strength of the anti-vaccinationists there is little probability of compulsory vaccination, even on a small scale, being enacted, however great be the necessity.

Chloroform in the South African War.

During the South African war deaths under chloroform occurred from time to time. Though the number was not excessive the suspicion arose that the chloroform might have deteriorated owing to some subtle changes, the result of heat, climate and other conditions incidental to active service, resulting in the production of substances which increased its toxicity. Of the original purity of the chloroform there was no doubt, as it was prepared from ethylic alcohol and sent out in the original bottles of one of the leading manufacturers. A number of samples of chloroform which had been used in South Africa, including portions of the chloroform under which death occurred, were submitted to Dr. Tunnicliffe, professor of pharmacology in King's College, London, as well as a sample returned from the China Field Force. He submitted a tissue especially susceptible to chloroform, viz., the cardiac muscle, to the action of the specimens. An excised rabbit's heart prepared according to Langendorf's method was perfused with an oxygenated sugar saline solution until the graphic record of the cardiac activity was constant. The heart was then perfused with a quantity of chloroform, to which 1 part in 6,000 of the chloroform to be tested had been added, and the record was taken. The heart was then immediately perfused with a known quantity of pure nutrient solution until the beats became normal. Then the heart was perfused with solution to which 1 part in 6,000 of pure chloroform had been added and the record taken. A large number of experiments were made. They showed that none of the samples differed from pure chloroform in toxic action on the heart, and that even the residues left after evaporation did not. In order to ascertain how the toxicity of originally pure chloroform is likely to be affected by conditions arising during military transit, it was subjected to the following manipulations: A sample was constantly shaken by means of a mechanical arrangement for several days. It was then exposed for several days to a temperature varying from 0 to 4 C.; subsequently it was exposed for several days to the direct July sunlight, and finally it was allowed to evaporate to half its bulk; part of the evaporation occurred quickly, the chloroform being subjected to a low pressure; part of the evaporation took place gradually, the chloroform being simply left open in the laboratory. The chloroform so treated was examined in the manner described and showed no effects different from that of pure chloroform. The conditions to which chloroform is likely to be subjected in warfare are not likely to be so violent. Hence the chloroform will probably not be affected. But Dr. Tunnicliffe recommends that it be not exposed during transit to strong light and be kept in as cool a place as possible in closely stoppered bottles.

An Ambulance Service for London.

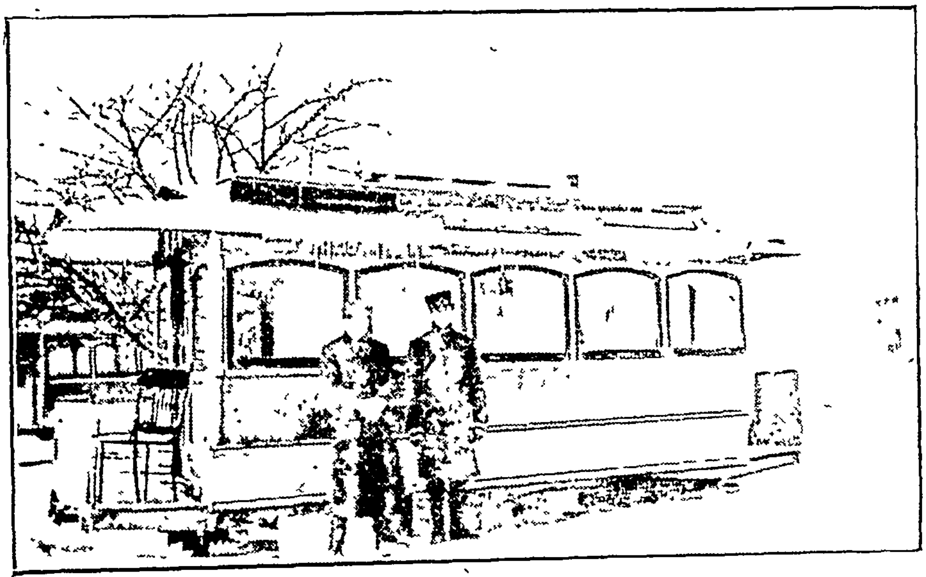
The committee of the Metropolitan Street Ambulance Association has made the following suggestions for supplying London with an efficient street ambulance service—a long-felt want: 1. A controlling authority responsible for a uniform well-organized ambulance service under the government of the London County Council. 2. The division of London into districts, or "accident areas," with a properly organized ambulance service arranged in each, consisting of horse or motor as well as hand ambulances. 3. The conjoint carrying out of the fire brigade and the ambulance services. 4. The stationing of ambulances at or in connection with the principal hospitals. 5. Keeping the police efficient in first-aid training and making them available in rendering aid, summoning an ambulance, and taking charge of the patient until the ambulance and attendant arrive. 6. The 800 fire-alarm telephone posts now existing, and all other telephones to be made available for calling ambulances. 7. The experience gained in New York, Chicago, Paris and other cities is more than sufficient to justify work on a scale large enough to provide for the removal of 13,000 to 15,000 casualties yearly.

Correspondence.

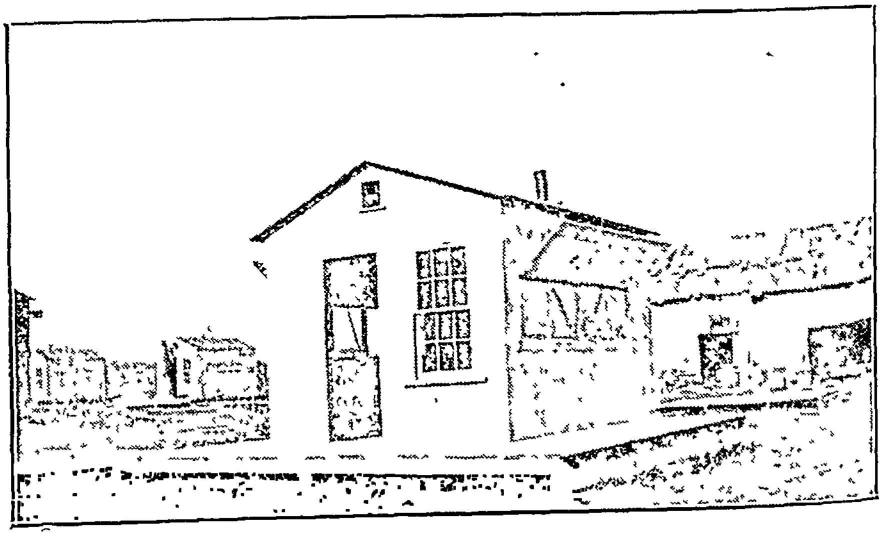
Pine Ridge Camp for Consumptives at Foster, R. I.

PROVIDENCE, R. I., April 1, 1904.

To the Editor:—Rhode Island started its first open-air camp for consumptives in June, 1903. The patients lived in the ordinary four-walled tent, the sides of which were kept rolled up except during violent rain storms. Twenty-two tents were pitched for living quarters, the cost of each being $15. An old barn served as a dining room, and a woodshed was used as a kitchen. From 25 to 35 patients were constantly under treatment, supported chiefly by contributions from the citizens of Providence. The same routine was followed in regard to treatment as practiced at other open-air camps, namely, living out of doors, good nourishing food and rest. The results were most gratifying. How to care for these patients in the winter was a question of importance owing to our limited resources. Unfortunately, there was not sufficient money in the treasury for the building of cottages, so the following plan was carried out: Individuals who had lost some member of their family or one of their friends by phthisis were asked to contribute $150 each for the erection of a cabin or shack as a memoriam. As a result of this plan, ten cabins were soon erected as illustrated in this article. They were built of yellow pine, 10 feet wide by 12 feet long, with sufficient light and ventilation, surrounded on three sides by a piazza 4 feet wide, and an attractive sign with the donor's name was placed on the door. The cabins were heated by a small coal stove in severe weather, and each cabin was occupied by two patients. These cabins were the most inexpensive serviceable quarters that we could put up. While considering this problem the idea occurred to us that unused street cars would make excellent living quarters for the consumptive. Two were donated by the Rhode Island Company. They were removed from their trucks, raised eighteen inches from the ground, refloored and provided with furnishings for one patient. These cars make excellent quarters because they are well built, provided with plenty of window space, and are capable of perfect ventilation. The consensus of opinion among patients is that they are more desirable than the ordinary cabin or shack. As consumption is pre-eminently a disease of the masses, and, therefore, requires a great expenditure of money on the part of cities and states to care for those afflicted, it certainly seems that the economic problem is one of great importance, and I believe that the unused street car, many of which are in the possession of the city traction companies, can be utilized as living quarters for the consumptive at much less expense, and that it is equally as serviceable as the modern cabin or cottage. The manager of the traction company of Providence told me recently that these unused cars sold for from $5 to $15 apiece. Camps could be started in the country in the vicinity of cities, capable of caring for many consumptives at a very small expense for equipment. Tents could be used from spring until fall, the patient using the street or trolley car for winter quarters. The results obtained in regard to treatment at the Pine Ridge Camp for consumptives, Foster, R. I, since its opening to December 1, 1903, is as follows:



Street cars as living quarters for consumptives, Pine Ridge Camp, Foster, R I



Cabin at Pine Ridge Camp, Foster, R. I. Cost complete $150.

There have been 59 patients under treatment for periods varying from two weeks to five months. Of these cases, there were admitted:

Incipient cases....................	8
Moderately advanced...............	15
Far advanced	36

Sixty per cent. of incipient cases were cured; in 30 per cent. of the moderately advanced cases the disease has been arrested; 14 per cent. of the far advanced cases show great improvement.

One hundred and eighty applications for admission have been received, many of which are at present on the waiting list.

W. H. PETERS, M.D.

Johnson's Early Sign of Pregnancy.

WASHINGTON, D. C., April 23, 1904

To the Editor:—Replying to the letter by Drs. L. M. Giffin and O. M. Gilbert, THE JOURNAL, April 23, page 1090, giving their experience with the Johnson early sign of pregnancy, I beg to say I noted the same condition, together with the intermittent softening, in Case 10, reported in my article in THE JOURNAL, Feb. 20, 1904, but made no mention of the softening and change in color of the fundus uteri observed in the laparotomy case because I was dealing solely with those conditions occurring in the intravaginal portion of the cervix uteri I have received a large number of letters making inquiry concerning the rhythm in intermittent hardening and softening and change in color of the cervix, but, I regret to say, I am not able to report on that important feature of the new sign, but hope to present a subsequent paper touching this fact in reporting subsequent observations. I thank Drs. Giffin and Gilbert for their timely observation and description and hope that other physicians will investigate the subject further. I claim that these changes in consistence and color observed in the fundus take place throughout the entire organ, consequently they occur in the cervix uteri and can be recognized on careful investigation. H. L. E. Johnson, M.D.

College Credit for Medical Study.

Chicago, April 27, 1904.

To the Editor:—I note in the letter from Dr. John Rogers, secretary of Cornell University Medical College, in The Journal, April 23, the statement that seven years are required to secure the bachelor's degree and the degree of M.D. May I ask if the Cornell University school now requires all students to take this combined course or if students are still admitted as formerly, with a high-school education, that is, the completion of forty-eight counts in the examinations conducted by the Regents of the State of New York? John M. Dodson.

[The above was submitted to Dr. Rogers, who replies as follows.—Ed.]

New York City, April 30, 1904.

To the Editor:—In reply to the letter of Dr. John M. Dodson, Cornell University Medical College admits students who have had a four years' high-school course, but requires that these students shall include in their preliminary education (and so in the 48 count regents' certificate required by law in New York State), algebra, plane geometry, United States history, two years of English and two years of Latin, including the first four books of Cæsar's Commentaries. A combined course of arts and medicine is optional at present. The number of those who take the combined course is, however, increasing each year in a very gratifying manner.

John Rogers, Jr., Secretary.

Not Professor Forel's Assistant.

Chiguy, Switzerland, April 6, 1904.

To the Editor:—From August, 1879, until March, 1898, I was the director of the Burghölzh Insane Asylum and professor of psychiatry at the University of Zurich, and I desire to make the following statement:

Dr. Carl Bertuhringer, who designates himself a representative of the so-called Koenig Medicine Company of Chicago, and who incidentally represents himself as a former assistant to Professor Forel at the Burghölzh Asylum, was never my assistant and never an assistant at the Burghölzh Asylum. He did, indeed, study medicine in Zurich, and, like other students, studied psychiatry with me, and practiced in the clinic as a so-called *practikant,* as did other students. Under these circumstances I once permitted him to hypnotize one patient. But he was never either my asylum assistant or my private assistant, and hence has no right to publish himself as such.

Another Dr. Bertuhringer (Dr. Hans Bertuhringer) was actually assistant physician in Burghölzh and is now second physician at the Rheinan Asylum, Canton Zurich. But this is quite another person. Dr. August Forel.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE USE OF ERGOT IN LABOR.

———, ——., April 15, 1904.

To the Editor:—In your query column I would like to briefly state the following case: Mrs. ——, a primipara, began having slight labor pains on Sunday, which recurred at intervals until Wednesday morning, when they came with more regularity and continued sufficiently strong and regular to prevent rest throughout the day. She slept from 9 p. m., Wednesday, until 1:30 a. m., Thursday, when pains again came on with considerable severity and continued to come about every 4 to 6 minutes, until 1 p. m., when an internal examination was made and dollar-sized dilatation found, the head occupying an L. O. A. position. At 3 p. m. the bag of waters broke and the pains became more frequent, but their character made it evident that not much progress was being made. The patient complained constantly and bitterly of continuous pain in the intervals, and had no rest and took no nourishment after 1:30 a. m. At 7 p. m. another internal examination was made, which showed absolutely the same conditions found at 1 p. m. It was then agreed that another physician should be asked to see the case, which was done. After satisfying himself of the conditions he ordered that a dram of ergot be given. At once, in the mind of the younger man, rose visions of three of the greatest teachers of obstetrics in America, all of whom he had heard say repeatedly: "Never, under any circumstances, give ergot until the uterus is empty," and it was with great reluctance that he complied with the older man's orders. Subsequent events, however, set his mind at ease, for inside of a half hour pains were coming regularly at three-minute intervals, were of excellent quality and the patient was resting nicely between pains, often sleeping. At 9 p. m. the baby was born, the placenta following 40 minutes later. It seemed that this one little dose of ergot transformed a tedious, exhausting, non-progressive labor into a perfectly normal one with the happiest results. Was it or was it not good obstetrics?

Young Physician.

Answer.—Ergot would be a valuable aid in obstetric practice to stimulate uterine contractions if it were not dangerous and uncertain. Its characteristic properties have been known for hundreds of years and at times it has been employed extensively. Now most authorities in obstetrics discourage its use because of its dangers. While a proper dose may simply stimulate contractions, increasing their strength and frequency only within safe limits, an excessive dose will cause constant or tetanic contractions. Such contractions, as is well known, are very dangerous to the child, because they shut off the blood supply of the uterus and thus disturb placental circulation and lead to intra-uterine asphyxia. Many still-births can be ascribed to this drug. Moreover, tetanic contractions of the uterus may lead to its rupture where there is some obstacle to the birth of the child.

It is not easy to specify the proper or safe dose of ergot because of the complicated composition of the drug. During the last twenty years several efforts have been made to determine its active principles, but so far with no agreement on results. Since we have no active principle and since the fluid extract varies in strength one should always use the most reliable preparation he can secure, and if it is used before expulsion of the placenta rather a small dose should be given. Moreover, if the physician contemplates giving ergot to increase labor pains he should assure himself that there is no obstacle to delivery and that the conditions are such that he can deliver rapidly in case tetanic contractions occur and the child is thereby threatened. After administering the drug he should remain with the patient to care for any emergency that may arise. With these rules of management clearly appreciated ergot may be used by a careful physician without danger and no doubt at times with advantage. At the same time one can understand that the drug should never be used by midwives, and that its careless use by physicians may be productive of great harm.

EQUAL TO LAWSON TAIT OR WILLIAM OSLER.

A correspondent sends us a copy of the *North Brookfield* (Mass.) *Journal* of March 11, 1904, in which appears a letter from a physician concerning the necropsy held on a patient in the presence of another physician, a nurse and a layman. The letter states in preface that "The sickness and death of our much respected citizen, ———, has cast a gloom over our townspeople, and has caused many to ask . . . . Could not there have been more done to save his life?" After expressing his regret that time and space do not permit a full and accurate description of the illness and death, the physician says: "I will simply state that the autopsy proved that the diagnosis I made the first day of Mr. ——'s illness was correct. Two days later my first diagnosis was verified by Dr. — — —— of ———, and later was confirmed by Dr. —— ——— of ———. Dr. —— informed the family on his arrival that no surgical procedure was then justifiable under the existing conditions, which judgment was proved by the autopsy to have been as reliable and correct as if given by the great Lawson Tait of England. The autopsy showed a large amount of ulceration in the right side where the obstruction occurred; two portions of the small intestines, one about four inches, and one about five inches in length were in a very much contracted and diseased condition; the appendix showed the result of previous inflammatory conditions, but at this time was intact and in proper condition. The immediate cause of sudden collapse and death in Mr. ——'s condition was probably due to an ulceration and perforation of the intestine, which was plainly seen at the autopsy. Therefore, at the request of friends I submit this simplified report, trusting it will save her who has been left to mourn this great loss from further annoyance or questioning by kind friends and neighbors, who little realize the pain and sorrow that may be caused by offered suggestions, and wise predictions given by those who are best fitted to judge of their own actual needs. And to those who have taken it on themselves to question any judgment or treatment which has been used in this case, I can but say, in the words of the poet—'Still we gazed, and still the wonder grew, that one small head could carry all they knew.' Furthermore, by our knowledge, which we have proved correct, as the autopsy showed, and by the careful, conservative judgment given by Dr. ——, I feel justified in saying that Mrs. ——, as well as this whole community, may ever feel that had we been able to obtain the services of William Osler, the recognized authority of the Unnited States, or had we held in readiness the operative hand of the great Lawson Tait of England, we could now but bow our heads in submission, while our hearts cry out in their sorrow, 'Thy will be done.' Respectfully, — — ——, M.D.," The sender of the newspaper makes the following comment: "This strikes a lay reader as extraordinarily bad taste. 'Methinks my lady doth protest too much.' "

TREATMENT OF NURSING SORE MOUTH.

North Carolina, April 25, 1904.

To the Editor:—Please give me the best treatment for nursing sore mouth (stomatitis)—a sure cure, a specific, if possible.

J. H. P.

Answer.—We are afraid that our correspondent, who wishes a "specific" or "sure cure," will have to apply to some one who deals in such things—a patent-medicine man or one of the journals that makes a specialty of specifics. Certain manufacturing chemists are also developing quite a line of these goods. A careful study of the causes of disease, of its clinical manifestations and of the influence exerted on it by carefully tried therapeutic agents leads to the safest line of treatment, but does not furnish "sure cure" prescriptions. Nursing sore mouth, like other parasitic diseases, depends on the presence of the disease-producing germ and the resistance of the tissues. The latter factor consists of two things: the local condition of the mucous membrane of the mouth and the general state of health of the child. The prevention of nursing sore mouth, therefore, depends on keeping the child strong and well nourished, avoiding injury to mucous membrane by rubbing off its tender epithelium in unnecessary efforts to clean the mouth, and on preventing contamination of the mouth with specific germs of thrush. The latter gain access to the mouth cavity in various ways, but probably most frequently from dirty nipples of nursing bottles, from sugar teats and from cloths and rags used by the nurse to "clean out" the mouth. The way to prevent such contamination suggests itself. When thrush is once developed measures to improve the general condition of the child should be at once instituted. The intestinal canal, which is generally in a diseased condition, should be cared for by the use of calomel, injections, etc., while errors in diet should be corrected. All sources of further contamination of the mouth, like sugar teats and dirty nipples, should be avoided. In the way of local treatment the mouth should be carefully washed before each nursing or feeding. The feedings should be at regular intervals and not too frequent. For the washing a solution of boric acid, soda bicarbonate or common salt may be used, or, perhaps, quite as well, sterile water. The object is to remove mechanically the necrosed patches and not to destroy the germs by any antiseptics. Much more depends on the method of washing than on the solution used. The child should be held so that a good light shines into his mouth, and the mouth should be held open so that the entire cavity is well seen. A soft, not too large, swab should be made by fastening sterile gauze to a sterile (i. e., boiled) stick. With this all inflamed or coated patches are carefully washed with the chosen solution. Conscientious and persistent management along these lines will result in a "sure cure" unless the child is in a very weakened state, with no tissue resistance, in which case gastrointestinal and other complications may lead to a fatal termination.

A PHYSICIAN'S CARD.

The following display ad occurs on a certain physician's card:

———— ———— ————, M.D.

Physician and Surgeon.

Ex-Coronor.
Ex-Health Officer.
Ex-Lcl. R. R. Surgeon.
Member —— State Med. Soc'y.
Author "———— Pocket Anatomy."
Ex-Vice Pres. —— Medical Society.
Member American Medical Association.
Ex-Secretary Inter-State Medical Society.
Member Southeastern —— Med. Society.
United States Surgeon (Pension Department).
Ex-Supreme Med. Examiner, Mod'n American Life Insurance Co.
County Physician to St. ————'s Hospital, Poor Farm and Jail.
President Local Board of the ———— Children's Home and Aid Society.
Member Med. Society of the College of Physicians and Surgeons, ————.
President Local Board of State Charities, Auxiliary to State Board of Health.
Special Lecturer on Anatomy in College of Physicians and Surgeons, ————, ——.

ETIQUETTE OF CALLS AMONG PHYSICIANS.

Iowa, April 25, 1904.

To the Editor:—Will you please have an answer to the following question printed in The Journal? I have recently located at ————, and wish to know whether it is my place to call on the other physicians in the town, or their place to call on me first. The other physicians hold that it is my place to call on them first, while I am of the opinion that I (being the stranger) should be the one called on. Please let me know which is correct.

W. T. S.

Answer.—It is an accepted custom for young physicians and newcomers to call on the older physicians and those of longer residence in the locality. It is a mark of respect and courtesy due from one locating in a new place. He thus announces his arrival and his desire to be received in professional circles and friendship. This question was considered in The Journal of Oct. 1 and 18, 1902.

THE ATLANTIC CITY SESSION.

Eureka, Kan., April 28, 1904.

To the Editor:—1. What will be the railroad fare from Chicago to Atlantic City and return? 2. Will there be a special car or train from Chicago? If so, when? 3. Can one buy a railroad ticket and get stop-over privileges at Philadelphia to attend the clinics?

E. J. Norman.

Answer.—1. $20.25. 2. Yes, at least one. Sunday, June 5, 2 p. m. 3. Yes. See The Journal, April 30.

Marriages.

Clifford Sater, M.D., to Miss Louella Teal, both of Cincinnati.

Michael Hoke, M.D., to Miss Laurie Harrison, both of Atlanta, Ga., April 20.

Paul E. Bethards, M.D., to Miss Elizabeth Merrill, both of Toledo, Ohio, April 26.

Charles M. Proctor, M.D., to Miss Clara Shute, both of Malden, Mass., April 12.

F. Hoyt Pilcher, M.D., to Clara Belle Page, M.D., both of Winfield, Kan., April 22.

Ferdinand L. Benz, M.D., Wheeling, W. Va., to Miss Broderick, at Baltimore, April 5.

John F. Sinclair, M.D., Philadelphia, to Miss Gertrude May Wilson of New York, April 21.

Richard Henry Stubbs, M.D., to Miss Ethelyn C. Burleigh, both of Augusta, Maine, April 20.

George W. Schwabe, M.D., Columbia, Mo., to Miss Lulu M. Stotts of Smithton, Ind., April 13.

William E. Ground, M.D., West Superior, Wis., to Miss Lila C. Bell of Washburn, Wis., March 22.

Frederick J. Will, M.D., Des Moines, Iowa, to Miss Ethel Aileen Israel of Boone, Iowa, April 14.

Frank M. Shelton, M.D., Independence, Kan., to Miss Vilotta Gilman of Independence, Mo., April 14.

Robert Rees Sinclair, M.D., to Miss Beatrice Merwin Hanan, both of Westfield, N. J., April 12.

Martin M. Lally, M.D., North Adams, Mass., to Miss Elizabeth Gertrude Nolan, at Baltimore, April 12.

Lindley H. Eshleman, M.D., to Mrs. Mable I. Nelson, both of Marion, Ind., at St. Joseph, Mich., April 13.

Harry Arthur McDaniel, M.D., Bonham, Texas, to Miss Lora Lyday Whiting of Bells, Texas, April 19.

James Farnandis Mitchell, M.D., to Miss Eliza Hutchinson Webb, both of Washington, D. C., April 20.

Arthur W. Herr, M.D., Cleveland, Ohio, to Miss Olga Dietrichs of Paris, France, at Cleveland, February 26.

Edgar Garrison Ballenger, M.D., Atlanta, Ga., to Miss Nora Clark Gorman, at Catonsville, Md., April 20.

Henry Sabine Leake, M.D., Williamstown, Mass., to Miss Bertha von H. Mundé of New York City, April 13.

Nathaniel Read Norton, M.D., New York City, to Miss Bertha d'Invilliers Weightman of Philadelphia, April 23.

John de B. Walbach Gardiner, M.D., surgeon U. S. Army (retired), to Miss Emily Carrico, at Washington, D. C., April 4.

Deaths.

Benjamin F. Dodson, M.D. Cincinnati College of Medicine and Surgery, 1853, a member of the American Medical Association, Wisconsin State Medical Society, and Green Lake County Medical Society, a pioneer practitioner of that district and one of the most esteemed and beloved citizens of Berlin, Wis., died at his home in that place, April 12, after an illness of one year, aged 72. The cause of death is not positively determined, but the autopsy demonstrated a hemorrhagic and necrotic left kidney, and a diseased condition of both suprarenals.

Abram Miller Henkel, M.D. New York University, 1868, a member of the American Medical Association, Virginia Medical Society, and National Association of Railway Surgeons, a member of the board of trustees of the Western State Hospital, one of the most prominent residents of Staunton, Va., died suddenly at his home in that place, from Bright's disease, April 19, aged 60.

Charlotte Blake Brown, M.D. Woman's Medical College of Philadelphia, 1874, for thirty years a practitioner of San Francisco, and organizer of many societies for philanthropic and charitable purposes, died at the Adler Sanitarium, San Francisco, April 19, after an abdominal section for intestinal obstruction, aged 57.

Isaac T. Wilson, M.D. New York University, 1851, the oldest physician in Quincy, Ill., and one of the organizers of the Adams County Medical Society, died at his home in Quincy, April 24, from pneumonia, after an illness of one week, aged 79. The Adams County Medical Society attended the funeral in a body.

Edward E. Jenkins, M.D. Medical College of the State of South Carolina, Charleston, 1853, a member of the American Medical Association, an esteemed citizen of Palatka, Fla., died at his home in that city, April 18, from malignant disease of the neck, after a long and painful illness.

John B. Mahoney, M.D. Harvard University Medical School, Boston, 1887, a member of the Massachusetts Medical Society, and formerly city physician of Medford, died at his home in that town, April 20, from Bright's disease, after an illness of three years, aged 42.

Edward L. Trudeau, Jr., M.D., College of Physicians and Surgeons, New York City, 1900, of Saranac Lake, N. Y., died, May 3, at his New York City residence after an operation for pleurisy complicating a two weeks' illness with pneumonia.

Narcissus Heru Matas, M.D. New Orleans School of Medicine, 1859, father of Dr. Rudolph Matas of New Orleans, who had lived for several years at Tucson, Ariz., died at the home of his son, in New Orleans, from apoplexy, April 13, aged 67.

Arch. Vandeventer, M.D., a patient in State Hospital No. 1, Fulton, Mo., and formerly a practitioner in Audrain and Monroe counties, committed suicide at the hospital, April 17, by cutting his throat, aged about 60.

Joshua M. Carey, M.D. Eclectic Medical Institute, Cincinnati, 1862, at one time a member of the Pennsylvania legislature, a veteran of the Civil War, of Elmira, N. Y., died at Mount Vernon, N. Y., April 20, aged 70.

Fred Van Ackeren, M.D. University of Würzburg, Germany, 1888, was found dead in bed at his home in Elgin, Ill., April 26. Death is supposed to have been due to an overdose of morphin or cocain.

Robert McL. Read, M.D. Harvard University Medical School, Boston, 1877, formerly city physician of Boston, died in Los Angeles, Cal., where he had gone in search of health, April 21, aged 55.

Henry M. Cox, M.D. College of Physicians and Surgeons, New York, 1871, medical inspector in the health department for 20 years, died at his home in New York City, April 25, from pneumonia.

Ernest W. Salter, M.D. Bellevue Hospital Medical College, New York, 1892, of Stronghurst, Ill., died in Bayonne, N. J., April 23, from pneumonia, after an illness of six days, aged 34.

John Moore, M.D. Indiana, 1897, a member of the St. Joseph County (Ind.) Medical Society, died from pneumonia at his home in Lakeville, Ind., April 23, after a short illness, aged 67.

E. Hazard S. Hutchison, M.D. Bellevue Hospital Medical College, New York City, 1881, died at his home in New York City, from pneumonia, April 13, after an illness of six weeks, aged 44.

Sumner Paine, M.D. Gross Medical College, Denver, 1897, of Boston, died at the Massachusetts General Hospital, Boston, from locomotor ataxia, April 18, after a long illness, aged 36.

Samuel T. Evans, M.D. University and Bellevue Hospital Medical College, New York, 1904, died from diabetes, April 11, after an illness of one year, at Sherman, Texas, aged 25.

James L. Perryman, M.D. Medical Department of the University of Missouri, St. Louis, 1854, died at his home in Belleville, Ill., April 22, after an illness of several months, aged 73.

John J. Smith, M.D. College of Physicians and Surgeons, New York, 1889, died at his home in Yonkers, N. Y., April 20, from chronic bronchitis, after an illness of one month, aged 38.

Thomas E. Barry, M.D. New York University, 1897, of New York City, died in Utica, N. Y., April 26, from septicemia following an autopsy wound, after an illness of four months.

Edward N. Wilson, M.D. Rush Medical College, Chicago, 1887, of Portland, Ore., died at Chippewa Falls, Wis., April 7, from locomotor ataxia, after an illness of one year, aged 44.

Theodore Bange, M.D. Miami Medical College, Cincinnati, 1881, died at his home in Cincinnati, April 18, of diabetes, aged 45. He served as coroner of Hamilton County in 1890.

Isaac P. Alger, M.D., oldest physician in Branch County, Mich., who retired from active practice in 1899, died at his home in Coldwater, April 19, from apoplexy, aged 83.

William Piper, M.D. Starling Medical College, Columbus, Ohio, 1857, of Bellaire, Ohio, died recently in California, at the home of his daughter, after a long illness, aged 72.

Edward A. Hite, M.D. Eclectic Medical Institute, Cincinnati, 1898, of Kokomo, Ind., died at Hope Hospital, Fort Wayne, Ind., April 15, after an operation for gallstones, aged 32.

Lyman W. Denton, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1878, died suddenly at his home in Rivera, Cal., April 2, from heart disease, aged 56.

William H. Jackson, M.D. University of South Carolina, Columbia, 1873, died at his home in Springville, N. Y., April 6, from pneumonia, after a long period of ill health.

James W. Montgomery, M.D. Hospital College of Medicine, Louisville, 1884, of Paoli, Ind., died suddenly while in the courthouse in that place, April 19, from heart disease.

Charles E. Farnham, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1889, died at his home in Grand Ridge, Ill., April 19, from heart disease, aged 39.

Albert M. Tate, M.D. College of Physicians and Surgeons, Baltimore, 1899, died suddenly at the home of his father, in Elberton, Ga., April 17, from heart disease.

Harry A. Hakes, M.D. Castleton (Vt.) Medical College, 1846, a member of the legislature in 1865, died at his home in Wilkesbarre, Pa., from apoplexy, April 20, aged 78.

David D. Thomson, M.D. University of Louisville, 1849, for half a century a practitioner of Louisville, died at the home of his son in Dallas, Texas, April 21, aged 80.

Guilford W. McCray, M.D. Castleton (Vt.) Medical College, 1857, died from apoplexy at his home in Buffalo, N. Y., April 18, after an illness of one week, aged 73.

John Sprigg Poole, M.D. University of Maryland, Baltimore, 1887, died from influenza, at his home in Poolesville, Md., April 23, after an illness of one month, aged 40.

Lascellis Dysart, M.D. Medical Department of the University of Iowa at Keokuk, 1864, died suddenly at his home in Higbee, Mo., April 11, from heart disease, aged 65.

Andrew P. Cox, M.D. Cincinnati College of Medicine and Surgery, 1877, died at his home in Coraopolis, Pa., April 21, after an illness of six years, aged 59.

Ezra H. Ferris, M.D. Medical College of Ohio, Cincinnati, 1846, who retired from active practice 40 years ago, died at his home in Champaign, Ill., April 10, aged 82.

Darius M. Purman, M.D. Medical College of Indiana, Indianapolis, 1876, of Phoenix, Ariz., died at Los Angeles, Cal., April 8, after an extended illness, aged 50.

S. Wasson Jones, M.D. Long Island College Hospital, Brooklyn, 1872, died from consumption at his home in Newark, N. J., April 18, after a long illness, aged 54.

John M. Fladger, M.D. University of Nashville, 1887, of Manning, S. C., died at an infirmary in Sumter, S. C., April 24, from Bright's disease, after a long illness.

George E. Talbert, M.D. Ohio, surgeon of the Fourteenth Wisconsin Volunteer Infantry in the Civil War, died at his home in Beaver Dam, Wis., April 16, aged 75.

J. R. Edwards, M.D., a graduate of a medical college in Virginia, but never a practitioner, died at his home near Shiro, Texas, April 7, aged more than 80.

John G. Senour, M.D. Bellevue Hospital Medical College, New York, 1878, died at his home in Troy, Ohio, April 21, from angina pectoris, after a brief illness.

Addison D. Elston, M.D. St. Louis Medical College, 1864, surgeon-major during the Civil War, died at his home in Jefferson City, Mo., April 22, aged 72.

Albert M. Younkin, M.D. Columbus (O.) Medical College, 1847, a retired practitioner of Florence, Kan., died at his home in that city, April 25, aged 79.

Kenneth F. Lane, M.D. Atlanta Medical College, 1895, died from pneumonia at his home in Montevallo, Ala., from lobar pneumonia, April 3, aged 32.

John A. Pearsall, M.D. New York Homeopathic Medical College and Hospital, 1876, died from diabetes at his home in Saratoga, N. Y., April 18, aged 53.

Patrick H. Evans, M.D. University of Michigan Homeopathic Medical College, Ann Arbor, 1880, died suddenly at his home in Jesup, Iowa, April 7, aged 71.

Franz Hugo Krebs, M.D. Harvard University Medical School, Boston, 1859, died at his home in Boston, April 22, after an illness of four months, aged 80.

Robert C. Lumsden, M.D. College of Physicians and Surgeons, New York, 1881, died recently from pneumonia, at his home in Rockaway, N. J., aged 44.

Thomas E. Murphy, M.D. Medical College of Alabama, Mobile, 1892, died at his home in Bethany, Ala., April 20, from pneumonia, aged 33.

Charles W. Bishop, M.D. University of Louisville, 1868, of Mattoon, Ill., died at Los Angeles, Cal., from rheumatism of the heart, April 7, aged 57.

T. H. Davis, M.D. Missouri Medical College, St. Louis, 1891, died at his home in East Atchison, Mo., April 20, after a lingering illness, aged 60.

David W. Ingalls, M.D. New York Homeopathic Medical College and Hospital, 1893, died at his home in Bridgeport, Conn., April 10, aged 35.

Joseph D. Sauls, M.D. Tulane University, New Orleans, died suddenly at his home in Saulsbury, Tenn., April 21, from heart disease, aged 71.

Camille A. Fortier, M.D. University of the Victoria College, Cobourg, Ont., 1881, died recently at his home in Florence, Wis., aged 70.

John Gordon, M.D. New York University, 1880, died at his home in West Park, N. Y., April 2, after an illness of more than a year.

J. K. Herman, M.D. Washington University School of Medicine, Baltimore, 1869, died at his home in Kossuth, Miss., April 16, aged 60.

Michael Tryon Livingood, M.D. *Jefferson Medical College*, Philadelphia, 1849, died at his home in Rossville, Ill., April 6, aged 79.

Bernhard Zartzin, M.D. Charkov, Russia, 1871, died at his home in Milwaukee, April 6, after an illness of several weeks, aged 57.

William F. Bessellieu, M.D. Jefferson Medical College, Philadelphia, 1855, died recently at his home in Monticello, Ark., aged 70.

Stephen O. Himoe, M.D. St. Louis Medical College, 1856, died at his home in Kansas City, Mo., April 19, from pneumonia, aged 72.

Andrew Coursen Sawyer, M.D., a surgeon in the Navy during the Civil War, died at his home in Albany, N. Y., April 16, aged 67.

George M. Lyman, M.D. Physio-Medical College, Cincinnati, 1865, died at his home in Croton, Ohio, April 16, from influenza, aged 63.

George H. Goltry, M.D. University of Buffalo, 1860, died at his home near Irelandville, N. Y., April 16, after a long illness, aged 71.

Isadore E. Prevost, M.D. Columbia Medical College, New York, 1839, died at his home in Rochester, N. Y., April 16, aged 96.

Charles F. Bruckner, M.D. University of Würzburg, Germany, 1852, died suddenly at his home in *Cincinnati*, April 25, aged 75.

James Harley Miller, M.D. Kansas City Medical College, 1892, died at his home in Newkirk, Okla., April 11, after a short illness.

David W. Edwards, M.D. Atlanta Medical College, 1866, died recently from pneumonia at his home in Wilsonville, Ala.

Amos Newton Stout, M.D. Kentucky School of Medicine, Louisville, 1889, died recently at his home in Ava, Ill., aged 44.

William B. McCormick, M.D. Medical College of Ohio, Cincinnati, 1837, died recently at his home in Foster, Ky., aged 91.

B. F. Edmundson, M.D. *University of Louisville*, 1871, of Edmunds, Tenn., died at Trenton, Tenn., April 12, aged 60.

James Weed, M.D., one of the earliest settlers of Muscatine, Iowa, died at his home in that city, April 20, aged 90.

Thomas M. Winters, M.D. University of Michigan, Ann Arbor, 1887, died recently at his home in Lansing, Mich.

Samuel Alexander Kell, M.D., of Fort Mill, S. C., died at Ardreys, N. C., April 10, after a long illness, aged 63.

Timothy D. Lougher, M.D. State University of Iowa, Iowa City, 1875, died at his home in Adair, Iowa, April 3.

Bernard Vogel, M.D., Germany, of Baltimore, died suddenly in that city from Bright's disease, April 14, aged 57.

W. R. Harrington, M.D. Meharry Medical College, Nashville, Tenn., 1900, died recently at his home in Paris, Ky.

Lovel B. Allen, M.D. Minnesota, died suddenly at his home in Minneapolis, April 13, from heart disease, aged 75.

Thomas J. Foster, M.D. Atlanta (Ga.) Medical College, 1860, died at his home in Dallas, Ga., April 7, aged 70.

Gosta Anred-Nordin, M.D., was found dead at his home in New York City, April 11, from chloral poisoning.

Goldsmith Goodin, M.D., died at his home in Coxville, Ind., April 12, from intestinal tuberculosis, aged 73.

D. R. Leech, M.D. Atlanta (Ga.) Medical College, 1855, died at his home in Charlotte, Tenn., April 23.

Henry T. Terlinden, M.D. Medical College of Ohio, Cincinnati, 1897, of Cincinnati, died recently.

S. O. Tillar, M.D., founder of Tillar, Ark., died in that place, April 14, after a short illness.

James S. Stevens, M.D., died at his home in Kensington, Philadelphia, April 23, aged 70.

T. R. Rogers, M.D., died at his home in Moundsville, W. Va., April 10, aged 72.

S. C. Ingersoll, M.D., died at his home in Deer Lodge, Mont., April 24, aged 91.

James H. Carty, M.D., died April 18 at Leominster, Mass., aged 92.

Book Notices.

A Manual of Fever Nursing. By Reynold Webb Wilcox, M.A., M.D., LL.D., Professor of Medicine in the New York Post-Graduate Medical School and Hospital. Illustrated. Cloth. Pp. 236. Price, $1.00. Philadelphia: P. Blakiston's Son & Co. 1904.

This is another work written for the professional nurse and appears to contain all the general knowledge which is properly required in addition to general instruction in the functions of the nurse so far as regards this particular class of diseases of which it treats.

The Practitioner's Guide to the Diagnosis and Treatment of Diseases of Women. By Gustavus M. Blech, Professor of Operative Surgery, Jenner Medical College. Cloth. Pp. 112. Price, $1.00. Chicago: M. Robertson & Co. 1903.

This is an exceedingly brief work. It is quite an undertaking in a certain sense of the word to attempt to put the whole subject of gynecology into a little over one hundred, not too closely printed, pages, including also numerous space taking illustrations.

Songs of All the Colleges, Including Many New Songs. Compiled and Arranged by David D. Chamberlain (Harvard) and Karl P. Harrington (Wesleyan) Cloth. Pp. 330. Price, $1.50, postpaid. New York: Hinds & Noble.

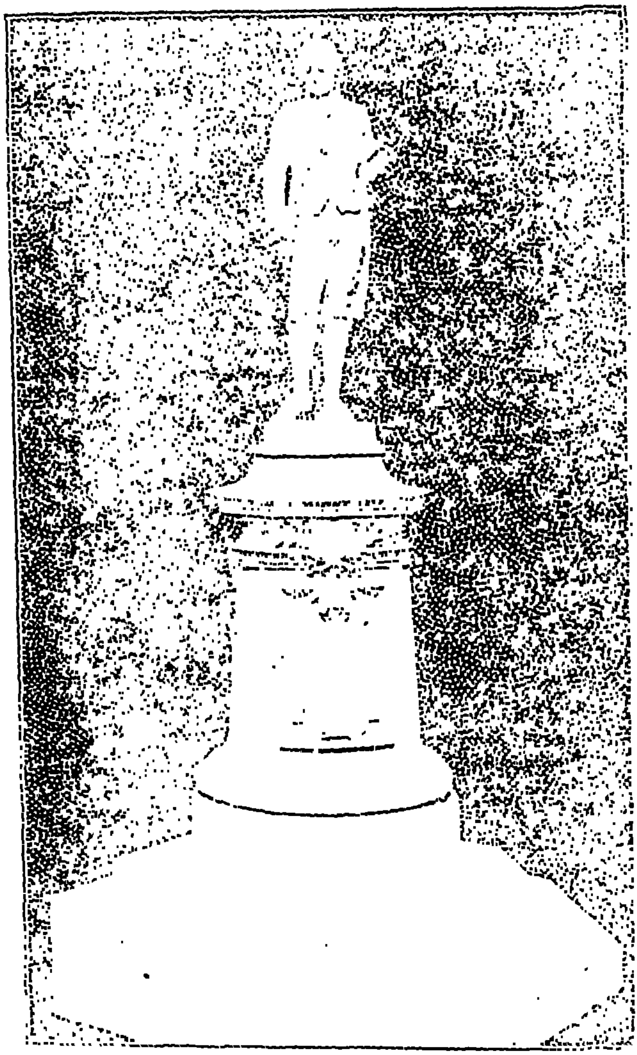
Comment is often made on the fact that there is less college spirit among students in technical and professional schools than among those in colleges of liberal arts. This no doubt helps to cause the lack of *esprit de corps* among the profession. College spirit will be a stimulant to united action by the profession, and one of the great incentives to college spirit is college song. We commend this book to our many student readers and to the members of alumni associations. It is well gotten up and the songs are well selected to represent the whole college world.

Association News.

THE ATLANTIC CITY SESSION.

Fifty-fifth Annual Session of the American Medical Association, To Be Held at Atlantic City, N. J., June 7-10, 1904.

Particulars of the Atlantic City session were given in The Journal April 30, pages 1156 to 1173, including the provisional list of papers to be read before each section, lists of hotels and meeting places, railroad rates, a list of clinics to be held at Philadelphia, and a description of the attractions of Atlantic City. Attention is called to the fact that railroad tickets in the territory of the Western Passenger Association will be on sale only on June 1, 2, 4 and 5, and will be good returning not later than June 13, unless extended.



The Rush Monument, Washington, D. C.
(See The Journal, April 30.)

Miscellany.

Clippings from Lay Exchanges.

A SPECIALIST IN HERPES ZOSTER.

"Henry —— has quit cutting shingles and gone to practicing medicine."—*Washington* (Ind.) *Democrat*, March 5, 1904.

HE REARRANGED THE ARTERIES.

"—— awoke about three months ago to find that he could not see out of one eye. . . . Several oculists . . . agreed that his eye had been paralyzed and that he would never see again. . . . Two weeks ago, however, Dr. —— a prominent eye specialist from the Academy of Medicine in Berlin arrived in Covington . . . and agreed to take charge of the case. . . . Dr. —— declared the blindness due to a dislocated artery behind the eyeball, which could be cured by an operation. The German specialist took out the eye, rearranged the arteries and then reset the eye-ball."—*New York Herald*, March 13, 1904.

THE NEW NOMENCLATURE.

"A paper was read by Dr. —— on 'Germatitis Medica Mentosie.'"—*Danville* (Ill.) *Commercial*, March 15, 1904.

A CASE OF NEURITIS A LITTLE OFF COLOR.

"A Brooklyn milk dealer has secured a verdict of $5,000 against the city. . . . He claimed to have sustained chromatic neuritis of the nerves and muscles of the left side."—*Sioux City Journal*, Feb. 23, 1904.

CASH OR CALCULI?—RESULTS OF HYSTERIA.

"Dr.—— . . ., submitted some specimens of rocks removed from one of his patients and a very interesting discussion on the manifestations of hysteria followed."—*Tulare* (Cal.) *Register*, March 8, 1904.

HARD RUBBER RIBS.

"—— has undergone a remarkable surgical operation. . . . Pneumonia left him with a persistent formation of pus in the pleural cavity. To relieve him, the surgeons removed the sixth and seventh ribs on the right side, and in their place substituted hard-rubber tubes to drain the chest. . . . The patient is convalescing."—*Oregonian*, Portland. "They expect new ribs to be grown to take the place of those removed."—*Cleveland Leader*, March 31, 1904.

TOO OFTEN ABNORMAL.

"Mrs. ——, on whom Dr. —— performed an abnormal surgical operation known as ovariotomy, Dec. 4, is making a rapid recovery."—*Neoga* (Ill.) *News.*

State Boards of Registration.

COMING EXAMINATIONS.

Mississippi State Board of Health, Jackson, May 10-11. Secretary, J. F. Hunter, M.D., Jackson.

State Board of Medical Examiners of South Carolina, State House, Columbia, May 17. Secretary, S. C. Baker, Sumter.

University of the State of New York, State Medical, Homeopathic and Eclectic Boards, New York, Albany, Buffalo and Syracuse, May 17-20.

Board of Medical Examiners of the State of North Carolina, Raleigh, May 18. Secretary, G. W. Pressly, Charlotte.

Nebraska State Board of Health. June 1-2, Creighton Medical College, Omaha. Secretary, Geo. H. Brash, M.D., Beatrice.

New Mexico Board of Health, Santa Fe, June 6. Secretary, D. B. Black, M.D., Las Vegas.

Iowa State Board of Medical Examiners, June 6-7, Des Moines, June 9-10, Iowa City. Secretary, J. F. Kennedy, M.D., Des Moines.

Michigan State Board of Registration in Medicine, Lansing, June 14. Secretary, B. D. Harison, M.D., Sault Ste. Marie.

Ohio State Board of Medical Registration and Examination, Columbus, June 14-16. Secretary, Frank Winders, M.D., State House, Columbus.

New Jersey State Board of Medical Examiners, June 21-22, Trenton. Secretary, E. L. B Godfrey, M.D., Camden.

Medical Society of Delaware, Dover, and the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, June 21. Secretary Medical Council, P. W. Tomlinson, M.D., Wilmington.

Medical Examining Board of Virginia, June 21-24, Richmond. Secretary, R. S. Martin, M.D., Stuart.

State Medical Society of Pennsylvania, June 28-30. Philadelphia and Pittsburg. Secretary, Isaac B. Brown, M.D., Harrisburg.

Iowa Provides for Reciprocity.—The legislature of Iowa has empowered the Iowa State Board of Medical Examiners to allow physicians to register without examination when they come from states whose requirements for certificates are equal to those of Iowa. The system will not be in operation until certain practical details are arranged. The addition to the law is in part as follows:

(*a*) A certificate of registration showing that an examination has been made by the proper board of any state, on which an average grade of not less than 75 per cent. was awarded, the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in this state, may be accepted in lieu of examination, as evidence of qualification, but in case the scope of said examination was less than was prescribed by this state, the applicant may be required to submit to a supplemental examination in such subjects as have not been covered. (*b*) A certificate of registration, or license issued by the proper board of any state, may be accepted as evidence of qualification for registration in this state, provided, that the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in this state, and that the date thereof was prior to the legal requirement of the examination test in this state. The fee for such registration shall be $50.

A further provision makes this apply only to states which reciprocate.

North Dakota April Report.—Dr. H. M. Wheeler, secretary of the North Dakota State Medical Examining Board, reports that at the written examination held at Grand Forks, April, 1904, 10 candidates were examined in 13 subjects and a percentage of 75 was required; 6 passed and 4 failed.

PASSED.

College.	Year Grad.	Per Cent
Rush Medical College, Chicago	(1901)	88
Illinois Medical College, Chicago	(1901)	83
College of Physicians and Surgeons, Chicago	(1902)	82
Starling Medical College, Ohio	(1896)	75
University of Minnesota	(1903)	78, 87

Those who failed were graduates of Barnes Medical College, St. Louis; Marion-Sims Medical College, St. Louis; College of Physicians and Surgeons, Chicago, and Wisconsin College of Physicians and Surgeons.

California April Report.—Dr. Geo. G. Gere, secretary of the Board of Medical Examiners of the State of California, reports that at the written examination held at San Francisco, April 5 to 7, 1904, 90 questions were asked on 9 subjects, and a percentage of 75 was required. Of the 62 who were examined 45 passed, 16 failed and 1 was conditioned.

Maryland Medical College, Baltimore	(1903)	65.71
University of Vermont	(1891)	69.21
Laval University, Montreal	(1902)	†58.80
Tufts Medical College, Boston	(1903)	‡38.50

*Also a graduate of Harvard, 1903. †Third examination. ‡Second examination, took only four subjects.

Montana April Report.—Dr. W. C. Riddell, Helena, secretary of the *Board of Medical Examiners* of Montana, reports that at the written examination held at Helena, April 5 and 6, 1904, 50 questions were asked on 10 subjects, and a percentage of 75 was required. Of the 13 who were examined 6 passed and 7 failed, as follows:

PASSED.

College.	Year Grad.	Per Cent.
University of Turin, Italy	(1900)	91.9
Northwestern University Medical School, Chicago	(1903)	83.7
University of Michigan	(1901)	79.5
American Medical Missionary College, Chicago	(1900)	86.3
College of Physicians and Surgeons, Keokuk, Iowa	(1898)	82.4
College of Physicians and Surgeons, Baltimore	(1898)	85.3

FAILED.

College.	Year Grad.	Per Cent.
Hospital College *of Medicine, Louisville*	(1902)	59.7
Dunham Medical College, Chicago	(1901)	64.0
University of New York	(1884)	*37.8
Dalhousie University, Halifax, N. S.	(1900)	64.7
Imperial Alexander University, Finland	(1894)	65.7
Detroit College of Medicine	(1897)	61.9
College of Physicians and Surgeons, Baltimore	(1893)	60.4

*Second examination.

Vermont Report.—Dr. S. W. Hammond, secretary of the Vermont State Board of Medical Censors, reports that at the *written examination held at Burlington, Jan. 13-14, 1904*, 80 questions were asked on 8 subjects, and a percentage of 75 was required. All 3 *that* were examined passed. Two were graduates of the University of Vermont in the year 1903, and one in 1901; their grades were 75, *81 and 85 respectively*. The questions asked were as follows:

MATERIA MEDICA AND THERAPEUTICS.

1. Name the *drugs that cause eruptions of the skin*. 2. Give *the dose of aconite*, veratrum viride, belladona, nux vomica, chloral hydrate and morphia. 3. Write a prescription for acute bronchitis. 4. Name the mydriatics. What is meant by the term? 5. Give the source and action of ergot. 6. Name the general and local anesthetics. 7. Give the composition of Dover's powder and its uses. 8. Name some of the internal antiseptics. 9. What do you understand by the incompatibility of drugs? Give examples. 10. Define the terms antipyretic, analgesic, hypnotic, anesthetic and antispasmodic and give examples of each.

OBSTETRICS.

1. Give the signs of pregnancy. 2. *Name some of the* principal diseases of pregnancy. 3. Give the fetal circulation. 4. Give the diameters of the fetal head. 5. Give the treatment of abortion. 6. Name six different presentations. 7. Name the varieties of placenta previa. 8. Name the causes of post partum hemorrhage and give treatment. 9. Give the symptoms of puerperal septicemia and its cause. 10. Give the treatment for ruptured perineum following labor.

PRACTICE OF MEDICINE.

1. Give the etiology, pathology and symptoms of pneumonia. 2. What is *arteriosclerosis? Its significance?* 3. Give the etiology, pathology and symptoms of typhoid fever. 4. Name some of the rational signs of disease. 5. Name some of the physical signs of disease. 6. Name some of the causes of dyspnea. 7. Give symptoms and treatment of acute cystitis. 8. What is otitis media and its danger? 9. What is meant by the terms infection, contagion, nidus, crisis and lysis? 10. Write a short article on the prophylaxis of pulmonary tuberculosis.

SURGERY.

1. How would you treat a simple fracture of the lower jaw? 2. How would you treat a fracture of the clavicle? 3. How would you *reduce a dislocation of the ulna backward* on humerus? 4. How would you treat a fracture of both bones of the fore arm? 5. How would you treat an ordinary pleurisy? How an empyema? 6. How would you treat the man mentioned in Question 6, Pathology? 7. Give treatment for perinephritic abscess. 8. In what cases is paracentesis abdominalis advisable? Describe operation. 9. Suppose that in a gunshot wound of the *inside of the thigh* near the middle a profuse hemorrhage suddenly occurred two or three weeks after injury, what would you do? 10. In case of gangrene of the leg in consequence of a thrombus in the popliteal artery, where is "the line" likely to form? What would you do and when?

PATHOLOGY.

1. What displacements are likely to occur in fractures of the lower jaw? 2. What are the displacements and symptoms in fractures of the clavicle? 3. Give symptoms of dislocation of the ulna backwards on the humerus. 4. What deformity and disability is liable to occur *after an improperly treated fracture of both* bones of the forearm? 5. Give differential diagnosis and course of pneumonia, pleurisy, bronchitis and phthisis. 6. Supposing the man mentioned in Question 6, Anatomy, was picked up on a *battle*field, 48 hours after injury, with the feces exuding from his wound, but without shock or fever, what would be your prognosis? 7. What is pyelitis? Its most common causes and symptoms? 8. In melanosis originating in the *small intestines*, where are the secondary depositis most likely to be found? 9. What accidents are liable to follow ligation of the femoral artery? 10. What is liable to occur after occlusion of the popliteal artery by an embolus or thrombus, and what are the early symptoms?

PHYSIOLOGY.

1. Describe the blood supply of bone. 2. Name the varieties of muscle fiber and give examples. 3. Give the composition of the blood. 4. Give the differences between arterial and venous blood. 5. Give the minute anatomy of a vein coat. (*b*) Of an arterial coat. 6. What and where are Brunner's glands? (*b*) Peyer's glands? 7. Explain the functions of the bile. 8. Describe the thoracic duct. 9. Give the structure of the spinal cord. 10. Describe afferent and efferent nerve impulse.

CHEMISTRY.

1. Define electrolysis. 2. Write the full names of the elements represented by the following symbols: K, Ni, Si, Sb, S, Na, Mg, Pb, Au, I, Co, Mn, Hg, Ag, Fl, P. 3. Which is the most abundant of the elements? Give its physical characteristics. 4. What is H_2O_2 and what are its uses in medicine? 5. How does chlorid of lime act as a disinfectant? 6. In what ways is Hg chiefly eliminated from the body? 7. Tell all you know about butyric acid. 8. A urine contains pus and gives an albuminous reaction. How will you determine whether such albumin be due to the pus alone and not to nephritis as well? 9. What pathologic change produces bile in the urine? (*b*) Give a test for bile in urine. 10. What do oxalate of lime crystals in the urine signify? (*b*) Uric acid crystals?

ANATOMY.

1. Briefly describe the histology of the skin. 2. To what organs are the pneumogastric nerves distributed? 3. Make a diagram of an anterioposterior, vertical section of the eye. 4. Describe the gross anatomy of the lungs. 5. Give the course of the circulation through the heart. 6. Make a diagram of the femur, indicating the points of insertion and lines of traction of the muscles likely to cause displacements in fractures near the middle of the bone. 7. Enumerate in order, from before backward, the different tissues divided in amputating the leg midway between the knee and the cipal changes in its course. 9. At what part of the abdominal wall is the tenderness most marked in typhoid fever and what viscera are situated beneath? 10. Make a diagram of and describe the tibia, with its relations to the fibula and the outer bones with which it articulates.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending April 30, 1904:

Schreiner, E. R., asst.-surgeon, granted three months' leave to take effect when a medical officer is sent to Fort McHenry, Md., to relieve him.

Little, William L., asst.-surgeon, granted twenty-one days' leave of absence.

Comegys, Edward T., deputy surgeon general, relieved from duty at U. S. General Hospital, Fort Bayard, N. M., and will proceed to Manila, P. I., for duty on transport to sail from San Francisco about June 1.

Crabtree, Geo. H., asst. surgeon, granted two months' leave, to take effect on May 30, 1904.

Wilcox, Timothy E., asst.-surgeon general, retired as brigadier general, U. S. Army.

Havard, Valery, deputy surgeon general, promoted to asst.-surgeon general, with rank of colonel, U. S. Army.

Corbusier, Wm. H., surgeon, promoted to deputy surgeon general, U. S. Army, with rank of lieutenant colonel, U. S. Army.

Kieffer, Charles F., asst.-surgeon, promoted to surgeon, with rank of major, U. S. Army.

Crabtree, Geo. H., asst.-surgeon, detailed for duty in connection with the Military Athletic Tournament, Madison Square Garden, New York City, N. Y., May 2.

Hughes, Leonard S., contract surgeon, at San Francisco, has been assigned to temporary duty at Fort Baker, Cal., when services are not needed in California he will return to duty in the Philippine Division, from which he has recently been on leave in the United States.

Adair, George F., contract surgeon, ordered from Fort Wadsworth, N. Y., to temporary duty at Fort Hamilton, N. Y.

Goff, Almon P., contract surgeon, granted an extension of one month to his leave of absence from the Philippine Division.

Tignor, Edwin P., contract dental surgeon, granted leave of absence for fifteen days, about April 30.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending April 29, 1904:

Hull, H. F., Wickes, G. L., Zalesky, W. J., asst.-surgeons, appointed assistant surgeons with the ranks of lieutenant junior grade, from April 12, 1904.

Strite, G. E., A. A. surgeon, ordered to the Naval Recruiting Station, Baltimore.

Balch, A. W., asst.-surgeon, detached from the *Machias* and ordered home and to await orders.

Seaman, W., asst.-surgeon, detached from the *Don Juan de Austria*, and ordered home and to await orders.

Grunwell, A. G., surgeon, sick leave further extended two months from May 2.

Payne, J. H., P. A. surgeon, detached from the Naval Hospital, San Juan, P. R., and ordered to the *Marietta*.

Ohnesorg, K., P. A. surgeon, detached from the Naval Hospital, Boston, and ordered to the *Topeka*.

Iden, J. H., asst.-surgeon, detached from the *Topeka* and ordered home and to await orders.

Stuart, A., asst.-surgeon, detached from the *Marietta* and ordered to the Naval Hospital, San Juan, P. R.

Strine, H. F., asst.-surgeon, detached from the *Annapolis* and ordered to the *Helena*.

Backus, J. W., asst.-surgeon, detached from the *Helena* and ordered to the *Annapolis*.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended April 28, 1904:

Pettus, W. J., asst.-surgeon general, granted leave of absence for seven days from April 26.

Cobb, J. O., surgeon, granted leave of absence for four months from May 1, 1904.

Wertenbaker, C. P., surgeon, to proceed to Toomey, Waterall, Logansport and Greenwood, La., for special temporary duty.

Rosenau, M. J., P. A. surgeon, one day's leave of absence, April 28, 1904, under Paragraph 189 of the Regulations.

Anderson, J. F., P. A. surgeon, granted leave of absence on account of sickness, for seventeen days from April 5.

Berry, T. D., asst.-surgeon, granted leave of absence for three days from April 22, 1904, under Paragraph 191 of the Regulations.

Hunt, Reid, pharmacologist, to proceed to New York for special temporary duty.

Alexander, E., A. A. surgeon, granted leave of absence for ten days from May 1.

Bailey, C. W., A. A. surgeon, department letter granting leave of absence for eleven days from April 22, 1904, amended to read eleven days from April 24.

Ballard, J. C., A. A. surgeon, granted leave of absence for ten days from May 5.

Goldsborough, B. W., A. A. surgeon, granted leave of absence for three days from April 27.

Rodman, J. C., A. A. surgeon, bureau letter granting leave of absence for six days from April 12, amended to read one day from April 13.

Rodman, J. C., A. A. surgeon, granted leave of absence for five days from April 26.

Watters, M. M., pharmacist, granted leave of absence for five days from May 3.

PROMOTIONS.

Richards, T. F., asst.-surgeon, is commissioned as P. A. surgeon, to rank as such from March 11.

King, W. W., asst.-surgeon, commissioned as P. A. surgeon, to rank as such from March 13.

BOARDS CONVENED.

Board convened to meet at Stapleton, N. Y., April 23, 1904, for the examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon Preston H. Bailhache, chairman; P. A. Surgeon A. C. Smith, recorder.

Board convened to meet at Washington, D. C., April 25, 1904, for the physical examination of an applicant for admission into the Revenue Cutter Service. Detail for the board: Asst.-Surgeon-General L. L. Williams, chairman; Asst.-Surgeon-General W. J. Pettus, recorder.

Board convened to meet at San Francisco, May 9, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; Asst.-Surgeon Carl Ramus, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from April 15 to April 29, 1904:

SMALLPOX—UNITED STATES.

California: Los Angeles, April 2-9, 2 cases; San Francisco, April 3-10, 2 cases.

Florida: Jacksonville, April 9-23, 6 cases.

Illinois: April 9-23, Chicago, 11 cases; Danville, 8 cases.

Indiana: South Bend, April 9-23, 7 cases, 1 death.

Kentucky: Covington, April 9-23, 3 cases; Louisville, April 1-14, 5 cases.

Louisiana: New Orleans, April 9-16, 3 cases.

Maryland: Baltimore, April 9-23, 11 cases.

Michigan: Detroit, April 9-23, 7 cases; Grand Rapids, April 16-23, 1 case; 87 localities, April 9-16, present.

Missouri: St. Louis, April 9-23, 22 cases, 2 deaths.

Nebraska: Omaha, April 8-23, 2 cases.

New Hampshire: Manchester, April 9-16, 1 case.

New Jersey: April 9-23, Camden, 5 cases; Trenton, 2 cases.

New York: Buffalo, April 16-23, 7 cases; New York, April 9-23, 3 cases.

Ohio: Cincinnati, April 8-15, 5 cases, 1 death; Cleveland, April 8-22, 3 cases, 1 death; Dayton, April 9-23, 14 cases, 2 deaths.

Pennsylvania: April 16-23, Allentown, 3 cases; Philadelphia, 32 cases, 9 deaths; Williamsport, 1 case; April 9-23, Johnstown, 3 cases, 1 [illegible], 9 cases, 1 death, 1 imported.

South [illegible] April 9-16, 2 cases.

Tennes[illegible] phis, 40 cases; Nashville, 11 cases.

Wiscon[illegible] il 9-23, 31 cases.

SMALLPOX—INSULAR.

Porto Rico: San Juan, March 1-31, 11 cases.

SMALLPOX—FOREIGN.

Austria: Prague, March 26-April 9, 8 cases.

Belgium: Antwerp, March 26-April 2, 24 cases, 3 deaths; Brussels, April 2-9, 2 deaths.

Brazil: Pernambuco, March 1-15, 20 deaths; Rio de Janeiro, March 13-27, 121 cases, 75 deaths.

Canada: Sydney, April 16-23, 54 cases, 1 death; Winnipeg, April 8-16, 1 case.

China: Shanghai, March 5-19, 22 deaths.

France: Marseilles, March 1-31, 14 deaths; Paris, April 2-9, 17 cases, 1 death.

Great Britain: April 2-9, Cardiff, 1 case; [illegible] Leeds, 3 cases; Newcastle-on-Tyne, 4 cases, 1 [illegible] 1 case; South Shields, 1 case, 1 death; March [illegible] London, 67 cases; Manchester, 6 cases; March 26-April 9, Hull, 17 cases, 2 deaths; Nottingham, 1 case; Glasgow, April 8-15, 33 cases, 3 deaths; Liverpool, April 9-16, 2 cases.

India: Bombay, March 21-27, 23 deaths; Karachi, March 20-27, 2 cases, 1 death.

Italy: Catania, March 31-April 7, 3 deaths; Palermo, March 26-April 9, 2 cases.

Java: Batavia, March 5-12, 20 cases, 1 death.

Mexico: City of Mexico, March 21-April 10, 13 cases, 4 deaths; Torreon, April 10-16, 19 cases, 35 deaths.

Netherlands: Amsterdam, April 2-9, 2 cases.

Russia: St. Petersburg, March 26-April 2, 7 cases, 2 deaths.

Spain: Barcelona, April 1-10, 8 deaths.

Turkey: Constantinople, March 27-April 10, 6 deaths; Smyrna, March 20-27, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, March 13-27, 6 cases, 3 deaths.

Colombia: Barranquilla, March 23 April 3, 1 death.

Ecuador: Guayaquil, March 19-26, 10 deaths.

Mexico: Merida, April 3, 3 cases, 2 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Feb. 27-March 5, 1 case, 1 death; Provinces, Feb. 13-March 5, 32 cases, 20 deaths.

CHOLERA—FOREIGN.

India: Calcutta, March 12-19, 58 deaths; Karachi, March 20-27, 1 case, 1 imported; Madras, March 12-25, 23 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Feb. 27-March 5, 2 cases, 2 deaths.

PLAGUE—FOREIGN.

Africa: Cape Colony, March 12-19, 1 case, 1 death; Johannesburg, March 18-20, 22 cases, 6 deaths; Pretoria, March 29, 2 cases.

Brazil: Rio de Janeiro, March 13 27, 2 deaths.

Egypt: March 12-26, 126 cases, 102 deaths; Alexandria, 1 case, 1 death; Port Said, 1 case.

India: Bombay, March 8-29, 2,705 deaths; Calcutta, March 12-19, 295 deaths; Karachi, March 20-27, 426 cases, 355 deaths; Madras, March 19-25, 1 death.

Formosa: Feb. 1-29, 114 cases, 80 deaths.

Peru: Lima, April 17, 148 deaths.

Straits Settlements: Singapore, Feb. 28, March 5, 2 deaths.

Medical Organization.

Florida.

Florida Medical Association.—This association held its thirty-first annual meeting at Live Oak, April 20, 21 and 22. This was the first meeting under the new plan, and it was very successful. The following was the representation by counties: Alachua, 16 members; Bradford, 11; Brevard, 7; Citrus, 5; Dade, 13; De Soto, 8; Duval, 30; Escambia, 21; Gadsden, 8; Hillsborough, 28; Jefferson, 10; Jackson, 12; Leon, 6; Madison, 5; Manatee, 5; Monroe, 6; St. Johns, 3; Suwanee, 13; Volusia, 15, and Washington, 6. This is a great increase over the previous membership and shows good work of the councilors during the past year. The following officers were elected: Dr. Edward N. Liell, Jacksonville, president; Drs. James M. Jackson, Jr., Miami, James F. McKinstry, Jr., Gainesville, and John S. Helms, Tampa, vice-presidents; Dr. James D. Love, Jacksonville, librarian; Dr. J. D. Fernandez, Jacksonville, secretary and treasurer; Drs. J. Harris Pierpont, Pensacola, councilor First District; Henry E. Palmer, Tallahassee, Second District; C. S. Brown, Live Oak, Third District; Jay H. Durkee, Jacksonville, Fourth District; H. M. Taylor, Crystal River, Fifth District; Joseph N. Fogarty, Key West, Sixth District; Williams L. Hughlett, Cocoa, Seventh District, and J. Harrison Hodges, Gainesville, Eighth District. Jacksonville was selected as the next place of meeting. Many interesting papers were read and discussed and the wisdom of separating the legislative body from the scientific was very thoroughly demonstrated, as quite a number of cases came up which were referred to the House of Delegates, and in that way did not take the time of the association. Dr. Joseph Y. Porter, Key West. was elected delegate to the American Medical Association, and Dr. J. Harrison Hodges, Gainesville, alternate.

Illinois.

Washington County Medical Society.—At the annual session of this society, held in Nashville, the standard constitution and by-laws was adopted and the following officers elected: Dr. James J. Troutt, Nashville, president; Dr. Richard E. Vernor, Nashville, vice-president; Dr. David S. Neer, Beaucoup, secretary, and Dr. Simon P. Schroeder, Nashville, treasurer.

Indiana.

Jasper and Newton Counties Medical Society.—Dr. George F. Keiper, Lafayette, councilor for the Tenth District, assisted at the organization of this bi-county society, on the standard plan, at Rensselaer, April 25. The society has an initial membership of 18 and the following officers were elected: Dr. Benjamin W. Pratt, Goodland, president; Dr. Peter J. Pothuisje, Remington, vice-president; Dr. Auburt L. Berkley, Rensselaer, secretary-treasurer; Drs. J. Walter Shafer, Morocco; Theodore E. Collier, Brook, and Arthur R. Kresler, Rensselaer, censors, and Dr. S. Curtis Johnson, Rensselaer, delegate to the state medical association.

Maryland.

Montgomery County Medical Association.—At the annual spring meeting of this society, the organization of which was noted in The Journal of January 16, held at Rockville, April 12, the standard constitution and by-laws was adopted.

The Medical and Chirurgical Faculty of Maryland.—The meeting at Baltimore, April 26 to 28, was in every way a success. About 350 members were in attendance, and the members from the counties were particularly in evidence. The expected opposition vanished when the matter was explained and the standard constitution was adopted with slight change. The banquet was attended by about 75. Dr. Robert W. Johnson, Baltimore, was toastmaster, and addresses were made in answer to toasts by the president, the president-elect, Dr. William H. Welch, Baltimore, and Dr. Clotworthy Birnie, Taneytown. Two very remarkable cases were exhibited during the meeting. Dr. Joseph H. Branham, Baltimore, showed a patient on whom he had performed pylorectomy for cancer of the stomach several years ago, and Drs. John W. Chambers and Julius Friedenwald presented a patient on whom the former had operated for chronic pancreatitis. Both were well several years after the operation. The following officers and committees were elected: President, Dr. Edward N. Brush, Baltimore; vice-presidents, Drs. Samuel T. Earle, Jr., Baltimore; DeWitt C. R. Miller and Julius A. Johnson, Easton; secretary, Dr. John Ruhräh, Baltimore; treasurer, Dr. Thomas A. Ashby, Baltimore; trustees, Drs. Henry M. Hurd, L. McLane Tiffany, Wilmer Brinton, and G. Lane Taneyhill, all of Baltimore, Charles M. Ellis, Elkton; Isaac E. Atkinson, Edward N. Brush, and Samuel C. Chew, all of Baltimore; James W. Humrichouse, Hagerstown, and John W. Chambers, Baltimore; councilors, Drs. William Osler, Robert W. Johnson, Thomas S. Latimer, Randolph Winslow, Henry O. Reik, all of Baltimore, Charles M. Ellis, Elkton, Charles W. Wainright, Princess Anne, J. McPherson Scott, Hagerstown, Clotworthy Birnie, Taneytown, Thomas H. Brayshaw, Glenburnie, D. C., R. Miller, the president, secretary and treasurer, and chairman of board of trutees and library committee ex-officio; memorial committee, Drs. Eugene F. Cordell, Joseph T. Smith, Frank D. Sanger, and Hugh H. Young, all of Baltimore, Philip Briscoe, Island Creek, and Edward L. Whitney, Baltimore; committee on scientific work and arrangements, Drs. Jeffreys Buck, Henry O. Reik and John Ruhräh, all of Baltimore; committee on public policy and legislation, Drs. William H. Welch and Thomas S. Latimer of Baltimore; Edward J. Dirickson, Berlin, Edward N. Brush, and John Ruhräh, both of Baltimore; delegates to the American Medical Association, Drs. Clotworthy Birnie, Taneytown, and William Osler, Baltimore; alternates, Drs. Samuel T. Earle, Jr., Baltimore, and Charles M. Ellis, Elkton; delegate to committee of the American Medical Association on National Legislation, Dr. Samuel T. Earle, Jr., Baltimore; committee to confer with the Maryland Pharmaceutical Association, Drs. Charles H. Riley, William F. Lockwood, and J. Frank Crouch, all of Baltimore; delegates to state medical societies, Pennsylvania, Drs. James M. Spear, Cumberland, D. C., R. Miller and W. Christian Sandrock, Baltimore; Delaware, Drs. George S. Dave, Rising Sun, William F. Hines, Chestertown, and Benjamin Whiteley, Catonsville, West Virginia; Drs. James G. Wiltshire, Baltimore, Richard W. Trapnell, Point of Rocks, and Lewis M. Allen, Baltimore; Virginia, Drs. Thomas Opie, Hugh H. Young and Isaac R. Trimble, all of Baltimore; North Carolina, Drs. St. Clair Spruill, Randolph Winslow, and Alexander D. McConachie, all of Baltimore; committee on fund for widows and orphans, Drs. Eugene F. Cordell. William Osler, Robert W. Johnson, and D. Webster Cathell, all of Baltimore, and library committee, Drs. George J. Preston, William Osler, Stewart Paton, Charles O'Donovan and J. Whitridge Williams, all of Baltimore.

Mississippi.

Natchez Medical Association.—Physicians of Natchez met, April 12, and organized a medical association with the following officers: Dr. Lewis H. Lamkin, president; Dr. Benjamin D. Watkins, vice-president, and Dr. R. Dunckley Sessions, secretary.

Pontotoc County Medical Association.—Fourteen physicians of the county met at Pontotoc, April 7, and organized this association on the standard plan, with the following officers: Dr. L. A. Ellison, Ecru, president; Dr. L. Leo Newman, Cherry Creek, vice-president; Dr. Thomas A. Williams, Redland, secretary and treasurer, and Dr. James A. Donaldson, Troy, delegate to the state association.

Missouri.

Scotland County Medical Society.—The physicians of the county met at Memphis, April 17, and organized a medical society on the standard plan, with the following officers: Dr. William E. Alexander, Memphis, president; Dr. Arthur L. Davis, Arbela, vice-president; Dr. Oscar F. Pile, Memphis, secretary-treasurer; Dr. Edward E. Parrish, Memphis, delegate to the state association, and Drs. Albert E. Platter, Memphis, Frederick M. Johnson, Gorin, and Dr. George K. Maynard, Arbela, censors.

Ohio.

Morrow County Medical Society.—Dr. Theodore W. Rankin, Columbus, councilor for the Tenth District, and Dr. Charles S. Hamilton, Columbus, met with the physicians of the county at Mount Gilead, April 20, and reorganized the county society on the standard plan. Dr. G. W. Morehouse, Sparta, was elected president; Dr. William L. Case, Mount Gilead, vice-president; Dr. Roland C. Spear, Mount Gilead, secretary; Dr. John H. Jackson, Edison, treasurer, and Dr. Walter C. Bennett, Mount Gilead, delegate to the state medical association.

Tennessee.

Lawrence County Medical Society.—With the aid of Dr. Otey J. Porter, Columbia, *a county medical society on the* standard plan has been organized at Lawrenceburg with the following officers: Dr. Robert H. Harvey, Lawrenceburg, president; Dr. Jasper N. Pickard, Summertown, vice-president, and Dr. C. M. Womack, secretary and treasurer.

Texas.

Eighth District Medical Society.—The physicians of this district, which comprises De Witt, Goliad, Victoria, Jackson, Lavaca, Matagorda, Colorado and Wharton counties, met at Wharton, April 12, and organized a district society on the standard plan. The following officers were elected: Dr. Walter Shropshire, Yoakum, president; Drs. Green L. Davidson, Wharton, James E. Pridgen, Thomaston, and Madison M. Pool, El Campo, vice-presidents; Dr. W. B. Cline, Lane City, secretary, and Dr. Oliver K. Radkey, Edna, treasurer.

Society Proceedings.

COMING MEETINGS.

American Medical Association, Atlantic City, N. J., June 7-10.

Utah State Medical Society, Ogden, May 10-11.
Assn. of American Physicians, Washington, D. C., May 10-11.
West Virginia State Medical Association, Fairmont, May 10-11.
Oklahoma Territory Medical Society, Oklahoma City, May 11.
New Mexico Medical Society, Albuquerque, May 11.
Illinois State Medical Society, Bloomington, May 17-19.
State Medical Association of Missouri, St. Louis, May 17-19.
Montana State Medical Association, Butte, May 18.
Kentucky State Medical Association, Lexington, May 18-20.
Iowa State Medical Society, Des Moines, May 18-20.
Ohio State Medical Society, Cleveland, May 18-20.
Indiana State Medical Association, Indianapolis, May 19-20.
New Hampshire Medical Society, Concord, May 19 20.

GERMAN CONGRESS OF SURGERY.

Held at Berlin, April 6-9, 1904.

(*Continued from page 1175.*)

The principal points in a number of the communications presented have been given in these columns recently, as published by the authors, such as Bakes' method of drawing up the omentum to envelope the kidney as a desirable modification of Edebohls' technic. (See page 1190.) Israel's experience with decapsulation was reported. In 6 cases of nephritis in which decapsulation was done, 1 patient died, 1 grew worse; in 2 other cases there was no improvement, but in the remaining 2 a certain amount of benefit was evident. He doubts whether this intervention has ever cured a case of true nephritis. Zondek thinks that his experiments on rabbits show that the Edebohls operation must be more or less harmful, as it temporarily deprives the organism of the circulation connecting the fibrous capsule with the renal parenchyma. Stern, Riedel and Kümmell also reported cases treated by decapsulation, the results being at best merely subjective improvement.

Renal Tuberculosis.

Kümmell of Hamburg has performed 48 operations on the kidneys on account of tuberculosis out of his total of 260, all but 15 of the 48 being women. In 5 the affection was bilateral. The others were treated by nephrectomy and 32 are still alive, after an interval of up to fifteen years. Some have been lost to sight. Krönlein has observed 51 cases of renal tuberculosis, about 30 per cent. of all the kidney affections received in his clinic at Zurich. All but 13 were women. He thinks this preponderance of the female sex is due to the effects of pregnancy and menstruation, causing conditions which lower the resistance of the kidney tissue. The age ranged from 20 to 40 in the majority. He removed the kidney in 34 cases. Eight of the patients died during the first nine months and 2 after six and ten years from tuberculosis of the lungs or of the other kidney. The 24 survivors are in perfect health to date, the interval being as long as fourteen years in some instances. He and Kümmell both deny the possibility of an ascending tuberculosis of the kidney, regarding it as inevitably of hematogenic origin. He distinguishes several forms of tuberculosis of the kidneys, the soft, abscess variety, the firm, caseous, the diffuse firm and the tuberous, his experience with a single case confirming that of Israel's in regard to the grave prognosis of this latter form. In one instance he had occasion to observe a tuberculous embolism. A tuberculous young man, lifting a weight, experienced a sudden pain in the back and his condition grew steadily worse. Extirpation disclosed a solitary tuberculous focus in the kidney, a hematogenic embolus. He is collecting colored plates of the findings in all the cases of kidney tuberculosis on which he operates, with a view to publishing an atlas of renal tuberculosis. Only 12 of the 34 were free from tuberculous lesions elsewhere. Nine of the 10 subjects who have died since have been examined postmortem, and in 6 there was no evidence of tuberculosis in the remaining kidney.

Substitution of Shaft of Long Bones.

Friedrich of Greifswald reported smooth healing and fine functional results attained in cases in which the entire diaphysis of the femur or tibia had been removed and substituted by a corresponding shaft from some other person after removal of the marrow and sterilization by boiling. His experimental and clinical research has demonstrated that the lengthwise growth of the bone proceeds normally from the epiphysis notwithstanding the interposition of a foreign body, if the epiphysis is intact. A silver plate inserted between the epiphysis and the diaphysis in young animals is pushed upward or downward toward the center of the shaft by the growth from the epiphysis. After six months it is nearly at the center of the shaft, sometimes the plate is found horizontal and sometimes tilted. If the interposed foreign body *is porous and* gives up salts needed for the production of the new bone, the growth of the new bone is facilitated, consequently a prothesis of human bone is the best of all. Among the patients he has thus treated is a girl of 8 requiring removal of the entire shaft of the femur on account of a myelogenic sarcoma. It was substituted by the tibia from a consumptive boy of 11. Healing was rapid and without any reaction, the dressings changed after six weeks. The child runs around with a splint and cane, entirely free from pain. The operation was performed last October. Another child had 14 cm. of the left femur substituted by a femur from a woman who had succumbed to gastric cancer. The marrow is removed from the bone and it is sterilized by boiling.

Injury of Hypophysis.

Madelung reported the case of a girl of 9 who, in consequence of a bullet wound in the head, presented unilateral amaurosis, remains of a hemiplegia and almost incredible progressive obesity. He is inclined to attribute the latter to some injury of the hypophysis or its vicinity by the bullet.

Artificial Increase of Resisting Power of Peritoneum.

Mikulicz commented on the importance of summoning the leucocytes to the spot in a septic process and stated that he goes still farther and summons them as an advance guard in readiness for a projected operation liable to induce septic soiling of the part. Flügge has demonstrated that subcutaneous injection of nucleinic acid enables rabbits to bear inoculation with doses of colon bacilli inevitably fatal for the controls. Mikulicz has applied the same procedure to man. Twelve hours before surgical intervention on the digestive tract he makes a subcutaneous injection of 50 c.c. of a 2 per cent. solution of nucleinic acid. The injection induces a slight, transsient local reaction with ocasionally a rise of temperature of not more than a degree, but never any disquieting general symptoms and no change in the urine. By the end of an hour or so the number of leucocytes drops below normal, then rises and attains in some cases 24,000, the maximum about twelve hours after the injection. The 34 cases in which he has thus artificially augmented the resistance of the peritoneum to infection from the stomach or intestines includes 7 cases of resection of the stomach and 15 of gastroenterostomy or enteroanastomosis. There was no postoperative peritonitis in any instance. He expressed his impression that the postoperative course was more favorable than usual. Kader of Cracow is engaged on similar research to enhance the resistance of the peritoneum. His plan is to induce phagocytosis by immunization from injections of bouillon cultures of streptococci or colon bacilli. This is followed by two waves of hyperleucocytosis. Mikulicz has abandoned his dry toilet and now flushes the abdominal cavity with saline, believing that the local hyperleucocytosis thus induced is of great value. Küster has his patients lie on their abdomen in after-treatment of septic peritonitis, placing them with a bolster under the chest, the head supported, the arms free, and sometimes a bolster under the pelvis.

KANSAS CITY ACADEMY OF MEDICINE.

Regular Meeting, held March 26, 1904.

The President, Dr. C. A. Ritter, in the Chair.

Some of the Cardinal Points in the Diagnosis of Abdominal Tumors.

Dr. H. C. Crowell, Kansas City, said that diagnoses which have, until the intervention of surgery, remained doubtful, are now made possible and positive without danger of increased mortality, by the exploratory operation. I wish to consider three kinds of tumors only, viz., cystomas, fibroids and pregnancy. Error sometimes arises from failing to exhaust the aids to correct diagnosis. In the case of a large abdomen let us bear in mind that it may not be what it appears to be. It may be fat, flatus or muscular action. It is important to know that the bladder is empty and percussion should then establish the presence or absence of free fluid in the peritoneal cavity. If a wave can be elicited which crosses the entire abdominal cavity we are probably dealing with ascites, although a large cyst might give the same wave. In ascites the abdomen will be flatter than if it be a cystoma. Search for a cause of ascites may be of use. Thus if disease of the heart, liver or kidneys be found, the presence of ascites is to be expected. Ascites associated with tubercular peritonitis is a very difficult condition for differential diagnosis. An exploratory operation may be necessary. I abhor the aspirator as a means of diagnosis.

Cystoma is to be differentiated from fibroid, pregnancy and dilatation of the stomach. Cystoma will be found to originate in the pelvis and not to be connected with the uterus. On light percussion it yields fluctuation which is limited to the tumor. It may be surrounded by an area of tympanitic resonance. In the recumbent position the abdomen is not so flat as in ascites.

Fibroid originates in the pelvis and is connected with the uterus so that moving the tumor moves the cervix and vice versa. If the fibroid be edematous deep percussion may give a sense of limited fluctuation. The uterine canal is elongated. Interstitial fibroma may be regular in outline and no harder than the pregnant uterus, in which case the signs of pregnancy must be depended on in order to differentiate.

The one sure sign of pregnancy is the auscultation of the fetal heart. In its absence we may diagnose pregnancy "if there be a swelling of the belly which alternately hardens and softens," which yields the uterine souffle rising in loudness while becoming hard and while becoming soft. With this there must be blue vaginal mucous membrane and softened cervix. If fibroid and pregnancy coexist the uterus will be irregular in outline and the bosses may be hard.

To diagnose a dilated stomach, wash out, inflate with air and percuss. The stomach tube and Davidson's syringe are to be used. Further, if the tumor be hepatic, splenic or renal, palpation will show that it does not originate in the pelvis. If it be hepatic it will rise and fall with respiration. If it be renal the colon will lie over it as a soft band. If it be splenic the sharp edge of the spleen can be grasped and the notch defined. The renal tumor may be further differentiated by the knowledge that hydronephrosis is phantom-like, appearing and disappearing, while movable kidney is subject to crises of severe pain (Dietel's sign), probably caused by twisting of the renal vessels.

DISCUSSION.

Dr. Binnie—I remember that Gaertner of Glasgow used to work on a diagnosis for days and then take great pleasure in making an autopsy in order to supplement his diagnosis. Hughlings Jackson of London added greatly to our stock of diagnostic knowledge by minutely studying his cases and then revising his diagnosis by postmortem study. I remember a case in which a diagnosis of obstruction of the bowels had been made. On operation a chronic appendicitis was discovered. The appendix was removed. Later a recurrence of the old trouble proved that the real cause had not been found. It has been suggested by Hemmeter of Johns Hopkins and also by Maylord that in certain cases of chronic dyspepsia or of nervous dyspepsia, after all treatment has been resisted the abdomen should be opened surgically and explored. Often a pathologic condition will be discovered, as, for example, carcinoma, which can be cured in the early stages. I remember an instance where Dr. Matas of New Orleans operated for carcinoma of the rectum and found uterine fibroid. I do not think I have ever palpated the appendix although I have sometimes thought so. Errors in the differential diagnosis between disease of the gall bladder and of the appendix can not always be avoided, as it is very difficult.

FIRST INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

Held at Nuremberg April 4 to 9.

The President, Professor Griesbach, in the Chair.

Great interest has been taken in this gathering to discuss subjects bearing on the physical and moral well-being of school children and teachers, and the hygiene of the school in general. The inscribed membership was 1,247, with invited guests bringing the total to over 1500. Twenty countries were officially represented. Eleven members from North America were inscribed, 60 from Russia, 48 from Great Britain, 51 from Holland, one each from Cuba, Turkey and Uruguay, 3 from Chili, 9 each from Denmark, France and Belgium, 5 from Japan, 4 from Italy, 15 from Spain, 341 from Austria and Hungary, and 621 from Germany. The English delegation comprised representatives of medical societies, school and public health boards, child study and teachers' associations, etc. It was presided over by Sir Lauder Brunton and he was formally elected to the presidency of the next congress, which will be held at London in 1907. There were three general sessions on consecutive mornings, and seven sections, one for hygiene of school buildings, day and boarding schools, with methods of hygienic examination and the physiology and psychology of educational methods and work; one for instruction of teachers and scholars in hygiene; one for physical training; one for disease and medical inspection; one for special schools for deaf mutes, the blind, etc., and one for the hygiene of the school children outside of school, with special reference to school and vacation camps and the relations of the home and the school, and the hygiene of the corps of instructors. The scientific program was opened by an address by Prof. Herman Cohn of Breslau to which reference was made editorially on page 1146 in our last issue. Professor van Johannessen described the conditions in Norway, saying that each school has its medical inspector, and that facilities for warm baths were provided in most of the Christiania public schools. The poorer children were given their lunch at many of the schools, the expense to the state amounting to about $43,200.

The Venereal Peril.

Professor Schusny of Budapest stated that in the Hungarian schools the teachers of physiology alluded to sexual questions in addressing the older boys advising them on sexual hygiene and in regard to the dangers of venereal disease. He advocated that parents should inform their children as they approached puberty, and said that for the last ten years he had delivered addresses along this line to the older boys just before they left school. Shower baths in schools were recommended.

Dr. Benda of Berlin advocated the abolition of the final examinations as too much of a strain. He would have the afternoons left free from study for exercises and games, and would restrict home study as far as possible. He believes in introducing the elective system into the preparatory schools, and suggests that provision for backward pupils should be made in the high schools as well as in the lower grades.

Classification by Mental Capacity.

Dr. P. Sickinger of Mannheim described the system in vogue there by which all school children are classed in three groups, the bright scholars, the moderately dull and the morbidly dull. This classification in the public schools has proved a great improvement from a pedagogic point of view, and its enforcement has not been difficult, while it is satisfactory to all the parties interested.

Ventilation.

The discussion of this subject brought out chiefly the failures and drawbacks of the systems in vogue. Dr. J. Kerr from London advocated for large schools direct mechanical movement of the air by large fans running at low speeds. All air ducts should be as large as could be afforded, and the outlets of low resistance to avoid "short-circuiting" when doors are opened. The minimum supply should be 2,000 cubic feet per capita per hour. The air should be well moistened, and for heating he prefers low pressure steam or water systems. He described his ideal as a large supply of moderately heated air moved by combined propulsion and extraction by fans with accessory heating of rooms, and doors and windows to be opened freely.

Stuttering and Stammering.

Gutzmann of Berlin reported the statistics collected in Berlin by the school medical inspectors. It was found in examining 3,000 school children that the proportion of stutterers under 7 years old was only 6 per cent., while it increased to 10 per cent. at 7, and 15 per cent. at the age of 11 to 12. He thinks that the strain of school life is responsible for this increase in the nervously predisposed. On the other hand, it was found that stammering decreased as education progressed, the proportion being 29 per cent. under the age of 7 and only 6 per cent. at 13 to 14.

School Games.

Dr. C. Dukes of Rugby proclaimed that time should be arranged for school games and that games should be made compulsory on all boys.

Duties of the School Medical Inspectors.

The German system allots four schools to one inspector. Twice a year he examines all the scholars entering the school, and makes a quarterly inspection of the sanitary conditions of the buildings, health of the children, and presence of contagious diseases. If requested by the school board these examinations are made oftener as occasion demands. The principal of the school sends to the medical inspector any child whose state of health during the intervals arouses suspicion. Quarterly meetings of the school inspectors for discussions are considered necessary. Liebermann of Budapest described the task of the school medical inspector as less that of a physician than as the expert adviser in matters of hygiene. The school is not a sanatorium, but an institution for the acquirement of knowledge, and this must not be obtained at the expense of health. As the state compels children to attend school it must guard them against injury therefrom, as it compels manufacturers to introduce safety devices to guard their employes from injury. The school medical inspector requires a special course of training in scientific hygiene and in pedagogics. The inspector should examine the children as they enter school, but the systematic weighing and measuring of the children—while valuable for statistics—is not the province of the school.

Infectious Diseases.

Dr. Hueppe of Prague, in his address, arraigned the medical profession for the unsystematic methods in which needed reforms are asked for from the administrative authorities. The things asked for are usually vaguely put and the grounds for the demand are not set forth in a convincing manner. Physicians must learn to help themselves; they must not go too far, and what they want must be stated clearly. He classes infectious diseases in three groups. The first comprises measles and whooping-cough, the typical school infections, in which susceptibility and predisposition do not count in comparison to the opportunity for infection. Mumps and chickenpox comprise the second group and are easily checked by isolation. The third group includes scarlet fever and diphtheria, which, although dangerous diseases, yet from the point of view of the school are of less importance than those of the two other groups. He thinks that disinfection might be dispensed with if the school rooms were carefully cleaned every day. The smaller the number of children in a room, the less danger from school epidemics. Tuberculosis in the teachers is a grave danger. Vacation camps and other opportunities for a stay in the country should be promoted in every possible way for weakly children. Le Gendre of Paris, in his address, remarked that the danger of infection is no greater from a tuberculous teacher than from similarly intimate contact with any tuberculous subject. The vitiated air, overexertion of the organs of speech and respiration, the fatigue from the long confinement and frequently insufficient nourishment combine to render teachers exceptionally susceptible to tuberculous infection. The danger of this infection is peculiarly enhanced in school rooms by the dust constantly stirred up in the air and brought in from the street, and the large number of persons in the room. This danger is enhanced still further by the common use of many articles, pencils, erasers, pens, etc., and moistening the finger with saliva to turn leaves and for other purposes. Prophylaxis should include reduction of the number of scholars in a room, better ventilation, prohibition of dry sweeping and rejection of all candidates for positions who are already tuberculous. Children predisposed to tuberculosis should be sent to schools organized for the purpose in the country or at the seashore, and tuberculous teachers should be given the benefit of sanatorium treatment.

Beside the 8 principal addresses delivered at the general meetings there were 153 communications presented in the seven sections and a fine exhibition of things pertaining to school architecture and equipment. The members of the congress were further interested in visits to a model school in the city, a two-story building in the shape of an E. The first floor is given up to the boys and the second to the girls. The middle pavilion is devoted to the gymnasium for both boys and girls, with assembly hall above. The shower-bath facilities are ample, the custom being to give a bath to seven or eight children at a time, once a week. Each child is supplied with a cap, bathing drawers and towel.

CHICAGO MEDICAL SOCIETY.

Clinical Meeting, held April 6, 1904.

Exhibition of Cases of Aneurism of the Aorta.

Dr. **Frank Billings** showed a man, 45 years of age, whose family history as regards tuberculosis, malignant disease and heart disease, was negative. The patient had an attack of typhopneumonia, which confined him to bed for a period of three months, when he was nine years of age, from which he recovered. At eighteen years of age he had specific urethritis, which lasted for three weeks. He denied any other venereal infection. Six years ago patient first felt a sharp pain in the region of the right shoulder, which came on suddenly. He described the pain as severe, beginning in the anterior portion of the chest, about an inch to the right of the right nipple, passing directly backward through the shoulder, and from the shoulderblade extending downward along the side of the chest, and sometimes across to the opposite shoulder. About a month ago the patient became incapacitated for work and noticed that his voice was failing. At about the same time dyspnea came on, which was aggravated by exertion. There was paralysis of the left recurrent laryngeal nerve. With these prominent symptoms and other minor signs, a diagnosis was made of aneurism of the aorta.

Dr. **Robert H. Babcock** showed a man, 53 years of age, laborer by occupation, who had been an inmate of the Cook County Hospital for the past seventeen months. The family history was negative. Personal history revealed gonorrhea at the age of nineteen. Patient denied syphilis, and did not give a history of any other important disease. His present trouble began a little over two years ago, with weakness and inability to work, associated with difficulty in breathing and pain. Dyspnea and pain were present only during exertion. Pain was felt in the lateral aspect of both sides of the chest. Present symptoms were chiefly those of dyspnea and change in voice, which was husky. His cough had taken on a peculiar character. He presented all the symptoms of a case of aneurism of the arch of the aorta, as determined by inspection, palpation and auscultation. The treatment had been the ordinary routine treatment of symptoms—rest in bed, light diet, iodid of potassium, etc.

Dr. **C. A. Elliott** presented a man, 54 years of age, in whose case a diagnosis of aneurism was first made two years ago. Patient had the symptoms of this disease, associated with others. A pulsating tumor could be seen about ten centimeters in diameter, which extended from the second rib to the fourth. The apex beat could be seen in the sixth interspace, about an inch to the left of the mammary line. A generalized arteriosclerosis was present with pulsations of all the superficial arteries. A capillary pulse could be demonstrated. The pulse showed the characteristic water-hammer pulsation. Tracheal tug was present, but not marked. On auscultation there was a harsh, roaring, systolic bruit at the apex, and a systolic murmur to be heard. Over the aortic interspace there was a double to and fro murmur, both systolic and diastolic. Over the tumor a double sound could be heard, both a systolic and diastolic bruit. Over the posterior aspect of the chest, at about the level of the eighth rib on the left side, one could hear distinct murmurs, both diastolic and systolic. On auscultation over the lower parts of the chest many râles were to be heard, and over the left side of the heart occasionally a squeaking rub was heard. The patient having been an athlete, Dr. Elliott thought it was reasonable to suppose that the strain to which he had subjected himself was an etiologic factor in his case. The size of the tumor was smaller than it had been.

Dr. **Charles L. Mix** exhibited a man, 49 years of age, with aneurism of the aorta. Three months before he presented himself to the post-graduate clinic, the patient was suddenly seized with an attack of severe pain in the left side, which persisted for a while, disappeared, and then recurred. He had had three paroxysms altogether. In addition there was dyspnea. Patient had had specific disease. The aneurism was near the heart. There was dilatation of the venules which one sees in cases of adhesive pleurisy, in some cases of mediastinal tumor, pericarditis, and sometimes in emphysema. In this instance they were scattered well around the chest. The other findings, as elicited by inspection, palpation and auscultation, were pointed out.

Dr. **George Galloway** reported a case of aneurism of the aorta.

Dr. **R. B. Preble** reported a case of aneurism because it presented so few symptoms. The patient appeared at his clinic complaining of dyspnea on exertion and on reclining, and was suffering from edema of the eyelids, which was manifest in the morning, and edema of the feet, which was manifest at night. During the night the edema of the lower extremities disappeared, while the edema of the face appeared, and vice versa, during the day. Inspection disclosed extreme tortuosity of the brachial vessels, with a high degree of arteriosclerosis, although the patient, a colored man, was only forty-three years of age. The patient denied a syphilitic history. The heart was considerably enlarged; the apex beat was situated an inch and a half to the left of the nipple line, and in about the seventh interspace. It was strong, but quite irregular in its action, and not particularly accelerated. Percussion disclosed an area of distinct dullness behind the sternum. Other features of the case were pointed out at length. Dr. Preble said the case was in no way remarkable from an aneurismal point of view, but it drew attention to the fact that in many cases aneurism was merely an incident. In his case it was an incident of a serious generalized disease, in that there were changes in the heart itself, and in the kidney, which were far more important and serious to the patient than the changes in the aorta.

The purpose in having these patients presented to the society was to draw renewed attention to the fact that aneurisms of the aorta were not uncommon; that they were extremely common, no two cases being alike, and anyone who thought, in order to make a diagnosis of aneurism, he must have auscultatory phenomena, coming on early, was mistaken, because many of the most serious cases of aneurism of the aorta had very little phenomena.

Dr. **Frank Billings** said that in the last few years he had had several cases in which he had made a diagnosis of dilated aorta, and of all of those that had come to autopsy, in more than one-half that diagnosis had been verified. Of the cases he had observed, all but one had occurred in elderly people, much older than any of the patients that had been shown, in people in whom one would expect to find atheroma, sclerosis of the vessels, etc. He mentioned the main points that were noted in taking the history of these cases.

Dr. **Arthur Dean Bevan** said he had noted three types of tumors within the chest, as shown by the *x*-ray, and there were one or two points of great value in making the differential diagnosis. In aneurism the outline was almost always a regular curve; while malignant growths or mediastinal tumors invariably had an infiltrating outline, if primary, as shown by the *x*-ray. Other pathologic processes presented an irregular, curved outline. He mentioned a case in which he assisted at an operation in which a positive diagnosis of mediastinal tumor was made by six good clinicians, the possibility of aneurism of the aorta having been eliminated. The mediastinal space was opened with the intention of removing a tumor; the patient died on the table. Postmortem examination revealed an aneurism of the aorta about the size of a fist.

Pneumococcus Endocarditis.

Dr. Frank Billings reported two cases of pneumococcus endocarditis, and exhibited specimens. This was the fifth case of acute endocarditis of pneumococcic origin he had seen in the last three years. He believed that Dr. Preble had collected three or four. A statement was made to him by a Philadelphia physician not long ago to the effect that he believed cases of acute endocarditis were more frequently due to the pneumococcus than to any other one germ; that the gonococcus came next, and then pus germs, etc. He said he would not care to sustain such a statement that the pneumococcus was the most frequent cause of endocarditis, or that the gonococcus was the second cause.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Chronic Rheumatism.

The medical treatment of chronic rheumatism, according to Huchard, in *Med. Press*, consists chiefly in the administration of the iodid of potassium and arsenic. If the patient complains of weakness the latter preparation may be given in the form of Fowler's solution five drops (.30) twice daily, or administered as follows:

℞. Sodii arsenatis ....gr. i |06
Aquæ ....℥x 300|
M. Sig.: One tablespoonful before lunch and dinner.

If the patient is vigorous potassium iodid is preferable, giving six grains (.35) daily. If the rheumatism be of arthritic character the iodid will be of little benefit. It should be replaced by the tincture of iodin, five drops (.30), three times a day, in a glass of water, gradually increased by one drop daily to ten or fifteen drops (.65-1.00), each time and continued for one month, when it should be suspended for ten days and recommenced. If an excess of uric acid is eliminated piperazin may be given:

℞. Piperazin ....ʒi 4|
Aquæ ....℥x 300|
M. Sig.: One tablespoonful twice a day for five days and suspended for five days.

Colchicum, in the opinion of the author, is of service only in rheumatism of a gouty nature. In acute attacks of chronic rheumatism the salicylate of sodium is frequently of good service, being superior to antipyrin, aspirin or salophen. Externally he recommends the application of the tincture of iodin to the affected area or ignipuncture. The following combination, also applied externally, is of value:

℞. Acidi salicylici |
Essentiæ terebinthinæ |
Lanolini, āā..........................ʒx 40|
M. Ft. unguentum. Sig.: Apply locally to the affected joints, with thorough friction, until absorption is complete.

When a great deal of pain is present Dieulafoy recommends a poultice of bread crumbs moistened with camphor and coated with the following mixture:

℞. Spts. camphoræ ....ʒii 8|
Ext. opii ....ʒi 4|
Alcoholis q. s.........................℥ii 60|
M. Sig.: Spread on the poultice and apply locally. Cover with gutta percha and keep in place with a flannel bandage.

Massage, electricity, warm baths, hot-air baths and turpentine vapor baths are also recommended.

Massage is especially indicated in the treatment of arthritis deformans by suppressing pain and avoiding ankylosis.

The ointment applied with massage is composed as follows:

℞. Tinct. nucis vom. |
Spts. lavendulæ, āā......................ʒi 4|
Lanolini |
Olei petrolati, āā.......................ʒvi 24|
M. Sig.: Apply locally with massage.

Warm baths should be given every two days for ten or twenty minutes, raising the temperature of the water as high as can be borne while the patient is in the bath. A hot sand bath is recommended by Bergeret when effusion is present in the joint, enveloping the joint in cotton wool and applying hot sand. The author also recommends various hydropathic establishments, including the sulphur mud baths.

The chronic form of rheumatism is much more amenable to treatment than the arthritic form, as the real cause of the latter is not yet fully understood, its nature being very complex, showing nervous, nutritional and inflammatory disturbances.

Yeo, in his "Ther. of Mineral Springs and Climate," states that patients suffering from gout, rheumatism and rheumatoid arthritis require similar climatic treatment. They are all influenced by cold, windy and damp localities, and all are benefited by residence in warm and dry situations. Sea coast resorts are of no benefit in these cases. Gouty subjects are prone to attacks of dyspepsia and biliousness in what is known as "strong" sea air. Dry inland resorts with southern aspect and protected from cold winds, are most suitable for rheumatic and gouty individuals. High altitudes are also unsuitable for such patients.

The most suitable winter resorts are either the warm, dry Riviera stations of France or the desert resorts in Egypt or Algiers. In summer and autumn moderate elevations should be sought as at Gastein, Ragatz and Wildbad. Prohibition of sea climates does not apply to young subjects of rheumatoid arthritis—for some of these cases have scrofulous affinities and may do well at the seaside or even on the sea.

Acute Tonsillitis.

The systematic treatment of acute tonsillitis is about the same in all the forms of infectious inflammation of the tonsils, so states George B. Wood in *Ther. Review*. He recommends that the patient be put to bed when fever is present and given soft foods. An active cathartic should be the initial treatment, giving calomel every half-hour in ¼-grain doses (.015) until two or three grains (.12-.20) are given, following this in about twelve hours by a mild saline purge. No drugs can be compared in effectiveness to the preparations of salicylic acid in the treatment of acute tonsillitis. Salol is not so desirable because of the dangers of carbolic acid poison. The author also states that sodium salicylate is not so desirable because of its depressant effect on the heart. He, therefore, prefers the ammonium and strontium salicylate combined, and to counteract any depressant action he combines them with strychnia as follows:

℞. Strych. sulph. ....gr. ss |03
Ammon. salicylatis |
Strontii salicylatis, āā...............ʒiss 6|
Aquæ destil. q. s. ad..................℥iii 90|
M. Sig.: Shake well and take one dessertspoonful in milk after meals.

In patients with irritable stomachs the salicylates are much more easily borne if given dissolved in half a glass of milk after meals. The nauseating effect of these preparations is due to their action on the gastric mucosa, so that when given with milk they penetrate the coagula, and as the coagula is slowly and gradually digested, only a small part of the salicylates is brought in contact with the gastric mucous membrane at one time. If after two days of active treatment with the salicylates an attack of acute tonsillitis does not show improvement, it is very doubtful if only a simple infection of the tonsil is present. After stopping the salicylates much benefit is derived from the use of some tonic, preferably strychnia, given to an adult in large doses—gr. 1/30 to 1/20 (.002-.003) three times a day. In children the use of the salicylates is very questionable and the dose should be carefully regulated to suit the age of the patient.

In children under 7 years of age the author seldom gives any drug except calomel. The local treatment consists in sterilizing, as far as possible, the crypts of the tonsils, the pharynx and the nasal fossæ. The latter should be cleansed with a warm saturated solution of boric acid, followed by an insufflation of a mild non-irritating antiseptic powder such as aristol. In those forms of tonsillitis characterized by congestion and swelling the essential feature in the treatment is to free the crypts from the pathologic germs. This may be accomplished by the introduction of strong hydrogen peroxid into the individual crypts by means of a fine applicator wrapped with a small pledget of cotton and saturated with the solution. After the acute stage is passed the crypts can be irrigated by a small stream of boric acid solution from a suitable syringe. In sensitive throats the peroxid alone can be applied, and if too irritating may be diluted to suit the case.

No remedy surpasses in efficiency the peroxid of hydrogen unless it is guaiacol used in 50 per cent. strength, combined with olive oil. This burns for a minute or so, followed by some anesthesic effects. The foregoing treatment should be carried out by the physician once a day. For home treatment a mild antiseptic throat wash should be used by the patient similar to the following:

℞.	Acidi borici	ʒiss	6
	Pot. chloratis	ʒiii	12
	Glycerini	℥i	30
	Aquæ destil. q. s. ad	℥vi	180

M. Sig.: Dilute with warm water and use as throat wash.

In ordinary gargling the fluid does not extend beyond the anterior pillar of the fauces. The fluid, however, can be made to reach the posterior wall by directing the patient to take a mouthful of the warm antiseptic solution and lie down on his back so that the head will be even with the shoulders, then holding the breath, allow the fluid to run back as far as possible and not swallow it. After letting it rest there for a moment the head should be thrown quickly forward and the fluid brought back into the mouth. Children can not carry out the above procedure successfully.

After the acute stages have passed the throat will be brought to its normal state more rapidly by the use of some astringent application or gargle. The author recommends for this purpose the glycerol of tannin, applied with a swab, twice a day. And as an astringent wash the following is recommended:

℞.	Ext. rhois globræ flu.	℥iii	90
	Pulv. potassii chloratis	ʒiss	6
	Glycerini	℥ss	15

M. Sig.: Shake well and mix one to three teaspoonfuls with a wineglass of water, and gargle three or four times daily until the soreness has disappeared.

Medicolegal.

Cost of Medical Services Evidence of Their Value.—The St. Louis Court of Appeals says that, in Abbitt vs. St. Louis Transit Co., which was brought by a husband to recover damages for personal injuries to his wife, the point was raised that there was no testimony that the bill for medical services was reasonable. The woman was attended by a regular physician, a graduate of a reputable medical school. He testified that his bill for attending her was $250, and that the husband gave him a well-indorsed note, but had not, at the time of the trial, paid him in cash. There was no testimony that the charge was reasonable, but the presentation of the bill and its payment or settlement by note or otherwise was some evidence that it was reasonable. In the absence of other evidence, cost is competent as tending to show value. The court can see no reason why that principle of law is not applicable to the cost of medical services as well as of property. It adds that it has examined the Missouri cases in which there were reversals because of a lack of proof as to the value of medical attention, and in all of them there was no proof at all as to what was charged or paid. The opinions, while they do not pass on the question, appear to assume that the presentation and payment of a physician's bill would be evidence of its reasonableness.

Venereal Disease and Marriage—Waiving Privilege.—The Court of Appeals of New York says, in the case of Svenson vs. Svenson, that it shares in the unwillingness of the Appellate Division of the Supreme Court (page 603 of The Journal of February 28, 1903) to assert the doctrine that an innocent and unsuspecting girl who marries a man afflicted with a chronic, contagious, and hereditary venereal disease, and who, therefore, refuses to consummate the marriage, may not procure a decree annulling the same because of the fraud involved in the existence of such a condition and its concealment from her. But, the court continues, the relief sought was denied on the ground that the defendant, two years after the marriage, had practically recovered. What a practical recovery from such a disease may import, where it has existed for more than two years, with the danger of its return and ultimate transmission, it is difficult, if not impossible, to determiine. But it was certain, at least, that at the time of the marriage the defendant was incapable of meeting the obligations and performing the functions of the marital relation, and was morally and physically unfit to become or continue to be the husband of a pure and innocent girl. When he concealed that condition from her, and still induced her to marry him in ignorance thereof, he was guilty of a base and unmitigated fraud as to a matter essential to the relation into which they contracted to enter. Obviously, the principle that refuses relief in cases of ordinary ill health, after the marriage contract has been actually consummated, has no application to a case like this, where there has been no consummation, and the disease is one involving disgrace in its contraction and presence, contagion in marital association, and includes danger of transmission and heredity that even science can not fathom or certainly define. The suppression of a disease including such dire and disastrous possibilities, directly affecting the marital relation, constitutes a fraud which clearly entitles the innocent party to a decree annulling the marriage contract, particularly when it has not been consummated. Again, the court says that it was evident that, the marriage not having been consummated, the usual considerations of public policy which apply to a case where the relation has by consummation of the marriage ripened into a public status did not exist here. There was between these parties little more than a contract to marry, and the court is aware of no principle of public policy which would be subverted by annulling this marriage, or which required it to compel the plaintiff to consummate the marriage and give herself up as a sacrifice to the possibilities involved in such a course. Nor does the court seem to think that relief could be refused the plaintiff on the ground of some supposed collusion between the parties, belief in which was presumably reached principally from the fact that the defendant appeared by an attorney, who, on the trial, waived the provisions of section 834 of the Code of Civil Procedure in the manner required by Section 836 of that act (relative to privileged communications), thus enabling the plaintiff to prove by a physician the physical condition of the defendant when the marriage contract was entered into, which she could not have done in that manner except by such waiver. If there remained in the defendant a single spark of manhood, the court asks, how could he have done otherwise? Moreover, it says, the record tended to disclose that this course was pursued by the defendant to avoid being called as a witness and compelled to testify to his own ignominy and disgrace.

Liability of Healers for Malpractice—Evidence.—The Supreme Court of Missouri, Division No. 2, has affirmed, in the case of Longan vs. Weltmer and others, a judgment for $7,500 damages for injuries alleged to have been sustained by the plaintiff by reason of the negligent, careless, and unskillful treatment by one of the employes of the defendants, "magnetic healers," under whose treatment she was at the time for some derangement of the stomach. The court says that, while treating her at the defendants' institution, this employe placed her on her back on a padded table, and put one hand on her stomach and the other hand under her knees, and bent her so that her knees almost touched her breast. He then placed her on her stomach on the padded table, and put his left hand on the small of her back over her spine, and his right hand under her knees, and bent her legs up until she screamed with pain. These manipulations resulted in the ligaments connecting the backbone and hip bone being ruptured and torn, and the back and spine and pelvic organs being permanently injured. The defendants contended that as the plaintiff's action was based solely on the negligent treatment of her, in order to constitute unskillfulness it devolved on her to show that the kind and manner of treatment adopted was not proper or usual in magnetic healing, and that, as she failed to do so, she was not entitled to recover. The court says that if this action was being prosecuted on the theory that the defendants were physicians, or that magnetic healing was one of the recognized professions, there would be more force in this position, but it was not, but on the ground that they held themselves out as magnetic healers, claiming and pretending to heal and cure all mental and physical ailments and diseases of the human mind and body through some power which they possessed peculiar to themselves. Nor was it necessary, in order to their liability for injuries sustained by the plaintiff, that they should have been or claimed to be practicing physicians, but if they undertook to cure the plaintiff of her maladies, and by the negligent or unskillful treatment of her, either by themselves or their employes, and by reason of such treatment, she sustained the injuries sued for, she was entitled to recover, just the same as she would be entitled to recover damages for the negligent or unskillful performance of any other kind of contract. It is a legal truism that any person who is legally responsible for his conduct is liable for all damages suffered by another which are the proximate result of negligence, carelessness, or want of ordinary care, and the reasons which prevail in such cases are much more cogent in the case of a person who deals with health and life, instead of property. Further, the court holds that while it was true that the physicians who testified on the part of the plaintiff did not claim or pretend to know anything about the practice of magnetic healing, they were nevertheless competent, from education and experience to testify whether the treatment which the plaintiff underwent was proper in any case, and especially in her condition. Simply because a person claims or pretends to possess certain powers of healing peculiar to himself is no reason why other persons, who do not claim such powers, but who know, from education and practice, are not competent to judge whether the treatment administered was negligently or carelessly done. Otherwise any nonprofessional person might undertake to treat a certain disorder, and—if defendants' position be correct in law, it matters not how carelessly or negligently performed—because, forsooth, no one could be found of the same pretensions to testify with respect to such treatment, the injured person would be without remedy. The contention, the court holds, is untenable.

7 *Importance [illegible] ment of Vasomotor Instability [illegible] icance of Irregularity of Cardiac [illegible] Bishop.

1. **Malignant Tumors.**—Wakefield's paper is supplementary to his former article in *Amer. Med.*, Nov. 22 and 29, 1902, and abstracted in THE JOURNAL, December 13.

2. **Tuberculosis.**—Sohon recommends northern Greenland as a summer resort for tuberculous patients. Sunshine is nearly continuous night and day; the atmosphere is germless, the scenery is striking, not cheerless, and the temperature, though low is not unendurable. Good wholesome food is easily carried and the appetite is improved by the environment. One is never beyond the reach of a sheltering harbor during the whole trip to the region, which can be made in ten days. Three months, he thinks, under such conditions may be time enough for the cure in patients not greatly run down, and is ample to give a person a fair start. He sums up the advantages as constant sunlight, germless, dustless air, an unvarying and bracing temperature inviting outdoor life and exercise, creating an appetite and the ability to digest and assimilate. Good recreation, novelties, etc., are also advantages.

3. **Reflexes in Relation to Eye Ground.**—Diller's conclusions are summed up in the following:

Of young men in health it may be said:
1. The knee-jerks vary greatly in their range and rapidity, being often difficult to elicit.
2. The achilles jerk is constantly present, varies much less than does the knee-jerk, and is seldom difficult to elicit.
3. The conjunctival reflex is extremely variable, being absent or faintly present in half of the cases.
4. The same may be said of the pharyngeal reflex.
5. The pupils are equal.
6. The pupils vary greatly in size, ranging from 2 mm. to 4.5 mm. and averaging 2.76 mm. in the light. The pupillary light reflex varies greatly, the range of the excursion being from scant 0.5 mm. to 3 mm. and the average 1.39 mm.
7. In the accommodation reflex the range of the pupillary excursion also varies greatly and is occasionally absent, the average range being 0.967 mm.
8. Convergence is more or less defective in fully half the cases.
9. The eye-grounds exhibit more or less deep or extensive cupping of the optic nerve with gray stippling in about an eighth of the cases, and in a few of these the appearance is suggestive of beginning gray atrophy.
10. The stereognostic appreciation is uniformly keen.
11. The same may be said of the muscular and spacing senses.

The number of persons on which these were based was 103 and the results of the experiments are briefly tabulated.

4.—This article has appeared elsewhere. See THE JOURNAL, xli, title 103, p. 1561.

6. **Digitalis in Shock.**—In Crile's experiments the fluid extract, the tincture and digitalin were used. In normal animals therapeutic doses intravenously administered caused a rise of blood pressure, which was sustained at the maximum for a considerable time. When given in larger or smaller doses repeated beyond therapeutic limits the blood pressure rose higher and more abruptly. If the over-stimulation fell short of a fatal breakdown, the intervals of alternation between the slow, powerful contractions and the rapid, weaker ones increased, only intermissions appearing later, finally the normal rhythm was re-established. Where the overstimulation reached a fatal breakdown, the alternations became more marked, and the heart suddenly stopped. If due to a large single dose or repeated smaller ones, the overstimulated heart became extremely irregular and the animal died suddenly from cardiac failure. Sometimes convulsions occurred. The respiration, when at all affected, was either impaired or arrested. It seemed on the average that in cases of shock the animal treated by digitalis did not live so long as the controls, certainly did not live longer. There was considerable idiosyncrasy in reaction of the different animals.

7. **Vasomotor Instability.**—Bishop calls attention to the element of vasomotor instability in estimating the significance of cardiac rhythm. He has often noticed that the regular pulse is attended with irregular auscultatory signs or vice versa. He thinks that cardiac irregularities may be only an attempt to compensate the misbehavior on the part of the vessels. One may fall into the errror of predicating trouble of the heart muscle when it is really a functional derangement of the blood vessels.

14 M[illegible]h Phototherapy, a Preliminary Report.
15 *T[illegible] Method of Burying the Stumps of the Appendix and Mesoappendix in Appendicectomy. Thomas E. Soules.

8. **Sclerosis and Ossification of the Veins.**—Beck calls attention to the occurrence of osseous degeneration or calcification in the veins, and to the fact that real osseous degeneration of the venous walls does not seem to have received previous attention. He uses skiagraphic illustrations of such a case, and notes the danger of using the ordinary methods of laced stockings, elastic bandages, injections into the circumvascular tissues, or ignipuncture, as well as their futility in such cases. They require extirpation as the only means which guarantees recovery.

9. **Congenital Hip Dislocation.**—Ashley and Mueller describe the after-treatment of bloodless reposition in detail, with illustrations. The most important part of it is connected with the removal of the first plaster. It is not a matter of time that regulates this, but the condition of the contraction of the capsular ligaments and fibers and of the iliotrochanteric muscles which have been stretched. The time will vary with the individual from six to eight months, and be determined by the stability. Examination then may reveal a normal position, with satisfactory and secure station of the head, or the head resting in the acetabulum, but easily dislocated. The latter condition requires a second cast in primary or modified primary position. The parts may be found in normal position, but with considerable rigidity. The usual after-treatment is then to be employed, exercise, massage, etc., but if the progress is unsatisfactory, correction is made in the cast. It may also be found that the head is in abnormal position, resting on the horizontal branch of the pubic bone. Depression is here indicated. The head may rest above the acetabulum, underneath the anterior superior spine, or it may be located behind the acetabulum—a relaxation. The meeting of these conditions should be individual and secondary operations with anesthesia may be necessary. The writers promise an amplification of this subject in the coming article.

10. **Infant Feeding.**—Chapin's object in writing this paper is to show that food chemistry has limitations in practical feeding, and that the chemical teachings of a few years ago are not the same as those of to-day. The advances in infant feeding have come not so much from the analyses that have been made as from clinical and physiologic experiments with cow's milk, altered or modified in other ways than by simple quantitative adjustment of the component parts. The advances that have been made are along the line of physiologic adaptation of various milks than from exclusive chemical studies. As Jordan says: "The ration may be chemically right, though practically wrong, but it is worth a good deal to the feeder to be assured that the nutrients which he supplies to his animals will meet their physiologic needs." This probably applies to human infants as well as to the lower animals.

11. **Typhoid Fever.**—In considering the efficacy of any plan of treatment the fundamental fact must be borne in mind that the disease varies widely from year to year, and also the certainty that a number of patients will die, no matter what is done. To treat the disease on any specified plan is to court failure. Still Manges claims that in spite of all that may be said to the contrary, few diseases are more amenable to rational methods. Few yield more brilliant results, provided we exclude cases of typhoid sepsis, uncontrollable hemorrhage, etc. The most vital detail is the regulation of the diet, and the most important in this is to give proper direction to the nurse that the mouth shall be kept moist and the tongue and fauces clean. Possible obstruction of the nasal passages should be suspected and remedied if found. The care of the mouth and nose is of foremost importance in preventing possible pulmonary complications. Too little stress has been laid on the systematic taking of large quantities of water. Milk should be the most important part of the diet, provided it agrees. The rule that Manges follows with delirious or somnolent patients is to give liquids alone. If the patient is only apathetic or perfectly rational, he asks if he is hungry and desires something more, and if so, he does not hesitate to add carefully prepared semi-solids. He has seen a rise of temperature follow these, but the general results of the more liberal feeding have warranted its use. Obstinate vomiting in this disease is always a most disquieting symptom. The best plan is to suspend all nourishment and medication for six or eight hours, and if this fails, use rectal alimentation until the stomach becomes tolerant. In some cases washing out the stomach may be advisable. He thinks the stomach tube is too little used. Another use of the tube may be mentioned, that is, with delirious patients, whose very delirium may be the result of starvation. The condition of the patient rather than the reading of the thermometer should be our guide. Unduly high temperatures or badly borne "normal temperatures" demand treatment. The use of the tub is a valuable aid, but the old barbaric procedures are no longer needed. A bath of 90 F. reduced to 80 or 78, accompanied with proper friction, will be found ample. The drop in the temperature is, he thinks, the least important. The effects on the nervous system, the resultant leucocytosis, etc., should be considered. The pendulum, he thinks, has swung a little too far as regards the use of antipyretics, since the coal-tar products judiciously used give good results. The old-fashioned method of using quinin, according to Liebermeister, is admirable in many cases. It consists in giving 10 grains at 6 p. m. and 5 grains at 7 p. m. followed by some acid. No immediate effect is observed but the general course on the following day is decidedly better. There is a form of fever which, at times, is more trying than hyperpyrexia, the moderate or low febrile rises in the fourth or fifth week. It is sometimes hard to account for this, but in other cases constipation and inanition may be to blame. The use of high oil enemas may change matters at once, and another method is the use of large doses of quinin. He does not object to the rational use of intestinal antiseptics (which he styles the "golden calf so devoutly worshiped by the manufacturing chemists"), but prefers the early use of calomel, systematic use of hydrochloric acid, and the prevention of undue intestinal distension. The routine washing out of the lower bowel with a quart of saline solution is excellent. The absorption of typhoid toxins from the intestinal tract and the contents plays a less important rôle than does the general production of typhoid toxins in the blood, spleen, etc. He remarks that there is too much routine in stimulation. In the early period no stimulants are needed. As the pulse rate raises and the patient becomes more apathetic and somnolent, the rational use of hydriatic measures is of value, and when the bath is preceded by whiskey and followed by hot food they leave little to be desired. If still more be needed, caffein in proper doses should be employed. A sinking of the blood pressure and failing circulation demand in addition the use of strophanthus or spartein in full doses, at short intervals, hypodermically. Do not give stimulants of this kind until they are actually needed, and when you do, give them in such a way that they are actually absorbed—not into the atonic stomach; "they might as well be given by absent treatment." As a routine drug he considers strychnia a danger. He has seen a case of strychnia poisoning with moderate dose, and thinks it must intensify some of the effects of the toxins produced by the disease. For analogous reasons he rarely uses digitalis.

12.—This article has appeared elsewhere. See The Journal, xli, ¶82, p. 1049.

15. **Method of Treating the Stump of the Appendix.**—This article needs the illustrations to fully explain it. After the appendix has been brought up, the mesoappendix is tied off at or about its center in sections varying from one to four, usually

two or three, according to length; each succeeding ligature being made to include some fibers of the preceding. The mesoappendix is then cut down to its base, the adherent mesentery dissected from the appendix and removed, and a circular incision made through the peritoneal envelope down to the musculoconnective tissue, at or near its tip, and carefully peeled off throughout its entire length to, or very near, its colonic junction, where a fine silk ligature is thrown around the denuded base of the appendix. Another ligature is applied about a quarter of an inch externally to this, and the cut made between the two. The appendix is then removed. The glove finger of peritoneum is then turned back and slit along the line of former mesenteric attachment and spread out, making a flat membrane equal in extent to the circumference and length of the excised appendix. This is then made to cover the appendicular stump, together with the bare ends of the mesocecal stumps, and with edges turned in, it is carefully stitched to either side, where the peritoneum shades away over the mesoileum. While this method may not be applicable in all cases Soules has found it entirely satisfactory in operations performed during the interval or in cases in which, for protection only, the appendix is removed incidental to laparotomies for other causes.

16. Acute Infectious Osteomyelitis of the Spine and Acute Suppurative Perimeningitis.—The direct relation of the spine to the important organs makes osteomyelitic processes in this region of special interest. Hunt reports a case in rather elaborate detail and collates the literature on the subject. The symptomatology is reviewed at length and the difficulties of diagnosis pointed out; the abrupt onset in young adults, the intense local vertebral pain with progressive symptoms of infection should always suggest osteomyelitis. With persistent local tenderness, increasing sepsis, and superficial signs of deep-seated suppuration the diagnosis becomes reasonably sure. With the formation of abscesses, however, amelioration may take place which is deceiving. Tuberculous caries should never be confounded with it. Acute articular rheumatism as a cause of confusion is rare, though it may be misleading, and the possibility of pyogenic infection of pre-existing spondylitis must be borne in mind. The prognosis is generally bad, though the later results of operation are much more favorable than former ones. One of the commoner complications of this condition is primary perimeningeal suppuration, and this phase of the subject is discussed. A number of cases have been reported by French authors, in which no primary focus of trouble could be ascertained, but Hunt thinks that none of these were correctly estimated, and that all cases have as their origin some slight focus of osteomyelitis. He says the vertebral column is rarely the seat of acute infectious osteomyelitis. Sixty two cases have been collected and are analyzed in the present communication. Great diagnostic difficulties are sometimes encountered owing to the immediate relation of the spine to the vital organs of the thorax and abdomen, and the spinal cord and its membranes. Retropharyngeal, mediastinal, retroperitoneal and paranephritic abscesses, pelvic abscesses, peridural suppurations, and general pyemia may be included among the complications. Peridural abscess or suppuration occurred in 24 of the 62 cases, 15 presenting grave symptoms of compression of the cord. The essentials of the clinical picture consist in symptoms of severe general infection associated with local signs of an inflammatory process in the spine. viz.. excruciating pain and tenderness, edema and fluctuation. The mortality is 50 per cent. Immediate and thorough surgical interference is the only treatment. The paper concludes with an analysis of cases of so-called primary suppurative perimeningitis, which term, he thinks, might be abolished from our nomenclature, and the cases considered as identical with acute osteomyelitis of the spine.

18. Pneumonia in Children.—Fisher points out the contagiousness of pneumonia and the necessity for isolation and the difficulties of diagnosis in young children. The temperature is a poor guide. The symptom which he thinks is most important is the variation from normal of the pulse and the respiratory ratio. Normally the respirations are about one to four of the pulse, but with pulmonary disorder the proportion is increased. It may be 1 to 3. There are several varieties of obscure pneumonia such as central pneumonia, where the physical signs fail. Infants or very young children rarely cough or expectorate the characteristic sputa. For the treatment he advises free ventilation and all the sunlight possible, and a temperature between 68 and 72, never warmer, rather cooler. For stimulating the emunctories, he would use a drop dose of tincture of aconite added to half a teaspoonful of spiritus Mindereri given three or four times at hour intervals until perspiration is produced. A hot mustard foot bath will aid in reducing the temperature. If the fever persists, sponging with alcohol and tepid water every half hour will be grateful. If we have a high temperature of 105 or more the infant should be closely watched for twitching or spasm, and he advises a cold pack around the chest repeated every half hour until the temperature goes below 103. The bowels should be relieved with castor oil, or better still, citrate of magnesia. The nutrition is important. The interval of feeding should be prolonged and the food given well diluted. Infants receiving 8 ounces of milk before illness should receive during the pneumonia, four of milk and four of water. If this is not well borne substitute whey for the milk. The patient should not be disturbed to give medicines or food at too regular intervals. It is poor judgment, he thinks, to awaken a sick child for this purpose. He makes it a rule not to disturb the infant oftener than every two hours during the day and rarely oftener than every four at night, in the ordinary cases of pneumonia.

20. Transillumination of the Stomach with Fluorescein.—Lincoln uses a lamp for transillumination of the stomach with fluorescein as the translucent medium. A description of the lamp has already been published in the *N. Y. Med. Jour.* The heat thrown out by the light is minimum, the lamp being immersed in the solution. His method is to give the patient 10 or more grains of quinin during the day of the examination or the previous one, and then introduce the lamp. The patient then drinks a glass of water, in which have been dissolved 30 to 40 grains of sodium bicarbonate, to render the gastric contents alkaline. Then another glass of water into which has been placed 1/8 gr. of fluorescein, 1 dram of glycerin, and 20 or more grains of sodium bicarbonate. The abdomen being bared, he then conducts the patient into the dark room or, if at night, simply turns out the lights. He has successfully examined persons of all weights up to 175 pounds, with all thicknesses of abdominal wall. He says this can be done by no other method.

29 *Reflections on the Surgery of Prostatic Hypertrophy. John G. Sheldon.

23. The Pulse as a Guide to the Life Insurance Examiner.—Babcock notes the over-estimation of the importance of frequency of the pulse, which depends more or less on the psychic and nervous conditions at work or some other factor that puts vagus control temporarily in abeyance. Other signs of nervousness must be noted by the examiner. It is a good plan to make nervous individuals lie down; the heart will then quiet down materially, and then after a time they may be told to jump up quickly or hop on one foot to show the rate of the heart. The important point in determining the significance in frequency is the tension. Ordinary nervous tachycardia rarely increased the blood pressure, though Babcock's experiences lead him to agree with Rosenbach that increase of the tension and genuine pathologic acceleration generally coexist. Of course, this does not apply to increased frequency due to valvular disease, but to that form of hypertrophy seen in certain cases of myocarditis; in such cases the physician should carefully study the degree of the arterial tension. It is well also to take the temperature to see if the increased pulse is due to fever and to ascertain whether the patient is over-strained by athletics or sexual indulgences. A pulse of over 85 or even 100 is not to be regarded as in itself indicating cardiac disease. It is possibly of more serious import in elderly persons than in the young, but if no signs of beginning inadequacy exist it is not of pathologic significance. A low pulse below 60 may be normal to the individual, not always indicating a cardiopathy, but it can not be the result of nervous or psychic influence, and its cause should be sought out before attributing it to myocardial degeneration. Two points are noted; first, that retardation due to prolongation of diastole from increased vagus inhibition is very different from apparent bradycardia caused by failure of some of the heart beats to send a wave to the radial artery. Secondly, that bradycardia in a man of middle age is far more likely to be of serious import than in the young, since it may portend cardiac exhaustion. If the peripheral vessels show slight thickening or minute points of calcareous deposit and the aortic second sound is unnaturally ringing, suspect myocarditis. Intermittent pulse by no means always indicates a serious pathologic disorder. It may be due to increased inhibitory influence sent down from the pneumogastric. Some nervous factor is probably at work, when intermittence is observed in young and apparently healthy subjects. When it occurs in the middle-aged it may have the same origin or be due to gouty poison. Irregularity is another thing. It may be due to the fact that the blood is altered in quantity or quality or it may be due to myocardial disease. Whenever the pulse occurs irregularly under exercise it probably means myocardial disease, but objective signs of cardiac disease usually develop in such cases. The pulse tension is alluded to as a subject of importance. It may be the earliest sign of a state of things which will some day mean serious inadequacy of heart or kidneys or both. He, therefore, recommends as a part of the paraphernalia of every insurance examiner some one of the appliances for clinical recognition of too high blood pressure, such as Gaertner's tonometer, which he thinks would save many a dollar to the company and spare the examiner much mortification.

24. **Rheumatic Eye Disease.**—Kalish calls attention to marginal blepharitis in early adult life, recurrent styes or chalazion, circumscribed bulbar conjunctivitis, limited or not to the eyeball, and striated keratitis. There is a form of conjunctivitis limited to the eyeball, never encroaching on the membrane of the lid, and usually affecting only the nasal side. He points out the differences between this condition and scleritis, from which the diagnosis may sometimes be troublesome. There is a variety of this disease restricted to the conjunctiva directly over the insertion of one of the recti muscles which frequently causes mistakes. Lastly he mentions striated keratitis, a rare disease of which he has seen several cases. Intentionally no mention is made in this paper of chronic conjunctivitis of the rheumatic and gouty, corneal ulcerations of later life, scleritis and other ocular diseases due to rheumatism, because they are fully described in text-books, whereas those here mentioned are seldom alluded to but yield likewise to antirheumatic treatment.

27. **Uncinariasis.**—Wainwright and Nichols have carefully examined 400 miners in the anthracite region from fifteen mines, including all nationalities, ten cover slips being examined in every case. In only one instance was the hookworm found, and from Stiles' findings it seems probably to be of the European type. Another interesting finding was that of the *Strongyloides intestinalis* occurring in a native of Russian Poland. It would show, therefore, as far as the inquiry has gone, that the hookworm has not obtained much of a foothold in the anthracite mines, though its danger is a serious one.

28. **Prostatic Hypertrophy.**—The points Thorndike specially emphasizes are summarized as follows:

1. That the catheter has as wide a range of usefulness as it ever had in the palliation of obstructing prostatic hypertrophy.
2. That the various operative procedures at present at our command are to be resorted to, with the exception of certain small classes of cases referred to in these remarks, after the catheter has ceased to palliate.
3. That the time for this operative interference is at the moment when the catheter has ceased to palliate and not after months or years of further and unavailing struggle to make it do so.
4. That the more radical operation of enucleation, on the one hand, and the Bottini operation with its various modifications on the other, are not procedures of the same kind, do not have the same object in view, and are in no sense to be weighed in the balance, the one class against the other. They should rather be contrasted, the one class as radical operations aiming at a cure, and the other as efficient palliating procedures, each having its own distinct indications for its appropriate use.

29. **Prostatic Hypertrophy.**—Sheldon concludes that:

1. Infection is the all important consideration in prostatics; 2, perineal drainage of the bladder relieves the patient; 3, many of these patients will not stand extensive operative procedures or long-continued anesthesia; 4, partial removal of the prostate, by the method herewith advised, will be tolerated by many infected patients, and a good result obtained; 5, perineal drainage of the bladder only should be done in desperate cases and in debilitated patients in whom morcellation is necessary. In these cases the prostate should be removed at the second operation.

Boston Medical and Surgical Journal.

April 21.

30 Introductory Lecture at University Bellevue-Hospital Medical College. Beverley Robinson.
31 *Resection of the Nasal Septum, with Report of Fifteen Cases. Leon E. White.
32 *Some Clinical Observations on the Care of Septic Wounds. Arthur L. Chute.

31. **Resection of the Nasal Septum.**—White claims that this operation has certain decided advantages. It has already been described by Dr. Otto T. Freer in THE JOURNAL, March 8, 1902, and Feb. 7, 1903. White claims for it accuracy, everything being under the eye of the operator, the avoidance of splints, rapidity of recovery, lack of pain, largely due to absence of trauma, the short after-treatment, freedom from sepsis, free respiration within forty-eight hours, availability for both bony and cartilaginous deflections, the utmost possible space in the nasal cavities being restored, not only straightening the septum, but reducing its thickness to that of two layers of the mucosa, and lastly, the lumen of the concave side is never lessened. He refutes the objections which have been made to it. The greater part of his paper is taken up with a description of the operation, with illustrations of the instruments he has devised for its easier performance. The result in all of his cases was most gratifying. The nose is not sore or painful; the only discomfort was the packing, which obstructed the breathing for the first two days. As a rule there is so little reaction after the operation that the patients are not confined to their beds, and under special circumstances are permitted to return to their work the second day, though a week's rest is desirable. Their general condition should be carefully watched, and hours of rest and recreation inquired into and tonics prescribed if indicated.

32. **Septic Wounds.**—The conclusions reached by Chute from clinical observation of a large number of cases are in substance as follows: Dry sterile gauze dressings are far preferable for the dressing of septic wounds since by their greater power of absorption, they most efficiently drain the wound, and by their slight mechanical irritation and comparative dryness make granulations more active and aid Nature's reparative power. While moist dressings, antiseptic baths and irrigating fluids have a depressing effect, they are, however, indicated when one can not obtain sterile dressings or can not depend on the aseptic skill of those who are to apply them. "Antiseptic poultices" are not to be preferred to sterile dressings, and are dangerous. When irrigating fluids are necessary or when for some unusual reason we are unable to make a wound

of such shape that it can be properly dressed, sterile salt solution should be the fluid employed. Peroxid of hydrogen should be avoided since in partially closed cavities or loose tissues the gas produced may aid in the spread of infection. For the routine method the dry gauze treatment is best.

Cincinnati Lancet-Clinic.

April 23.

33 *Malignant Neoplasms of the Kidney. With Report of a Case. E. O. Smith.
34 Important Cases of Appendicitis, with Deductions. J. G. Carpenter.

St. Louis Medical Review.

April 23.

33. **Malignant Growths of the Kidney.**—Smith reports a case and describes the usual symptoms, diagnosis and prognosis. In the case reported there were no symptoms except the presence of the tumor, which was enormously developed and resembled a cystic condition. In conclusion he emphasizes the fact that the only hope in malignant neoplasm of the kidney is complete extirpation, the earlier the better. The early recognition of the condition is important. The ability to recognize small renal growths comes from frequent practice in palpating the region. He suggests that the renal region be frequently and repeatedly palpated in every case with obscure urinary symptoms.

44 Medical Folklore of Childhood. Harriet C. B. Alexander.

36. **Insanity.**—Burr's address calls attention to the limitations of our knowledge as yet existing in regard to insanity, the large amount of crude data that we have on hand, which needs new methods of research to enable it to be utilized for fruitful pathologic and therapeutic results. He doubts the autointoxication theory that is becoming popular, at least as regards its universal application. In some types an inherited congenital defect must be recognized. The popular mind is too pessimistic regarding the curability of insanity, though undoubtedly certain forms are incurable, of which he mentions paresis and paranoia. There is one incurable, incorrigible form to which he devotes considerable space, that is, the high-class imbecile, including the criminal defective and moral insane. He points out the expense to the state from such cases, and says that the jail and house of correction contain imbeciles committed for short terms who should be under control or legal restraint throughout their natural lives. It would be cheaper to segregate these high-grade imbeciles for life under conditions in which they would be obliged to work for their own sustenance. The imbecile criminal is not reformable. The address closes with a few remarks on treatment, including the need of quiet and diet, and keeping the bowels well opened, followed later by judicious exercises and individual management. He says a word for blood letting in acute mania of the plethoric cases. He mentions alcohol as a stimulant in exhaustion conditions, though he would advise against encouraging the habit.

37. **Bright's Disease.**—Elliott reviews the dietetic management of Bright's disease, the exclusion of foods producing alloxuric bases such as meat extracts, broths, animal foods, certain green vegetables, fruit containing kernels, cranberries, yolk of eggs, liver, kidney, sweetbreads, all malt liquors and alcohol, and the restriction of the class of proteid foods to control within certain bounds the formation of urea. The regulation of the amount of proteid food is the main consideration of the dietary of Bright's disease. The degree in which we should reduce the albumin depends on the character of the renal lesion, the more nearly the disease approaches the acute form the more exclusively should milk be used as the chief source of proteids. Of course, it will require modification to make it perfectly satisfactory. In chronic nephritis the question of diet is more involved. We can not restrict the albuminous foods so much and the milk diet is not favored at the present time. The free ingestion of fluids may clear out the kidneys in certain chronic cases when the permeability of the kidney is regained. Special care should be given to the heart and circulation, as high tension and cardiac failure are threatening elements. The rules of cardiac hygiene must be scrupulously observed. Restriction in the amount of ingested fluids is one of the most important of these rules. What promises to be an important advance in the therapeutics of Bright's disease is, he says, the treatment by dechlorination suggested by Widal and Javal, whose observations have been confirmed by Mercklen and Courmont. (See THE JOURNAL, xli, p. 1171.) He has had opportunity to demonstrate the advantage of this method in two cases. As regards medicinal treatment we should not expect too much. The policy should be non-interference except where developing complications give positive indications. All drugs belonging to the class of diuretics are to be avoided in acute inflammatory conditions; even the simple alkaline diuretics form no exception. A careful regulation of the bowels to secure free daily passage is essential, and the greatest advantage will follow colonic lavage. The beneficial action of this procedure on the kidneys is obvious. In chronic parenchymatous nephritis he speaks well of the use of the prolonged administration of iron as being required more than in ordinary systemic anemia. Diuretics have a limited field of usefulness. The most that can be accomplished is secured by the administration of simple saline diuretics, which, by producing alkaline reaction of the urine, may improve the renal drainage by dissolving out the albuminous plugs which obstruct the tubes. In chronic interstitial nephritis the main thing is the care of the heart and circulation. As regards the use of digitalis, it should never be employed during the stage of cardiac hypertrophy and before signs of compensatory failure supervene. When nitroglycerin is used in association with digitalis the time of administering the former should be about an hour after the digitalis has been given. Conservatism in dosage should be observed. He speaks unfavorably of the surgical treatment of Bright's disease in general, though he says there is no doubt but that the operation has its place. In movable kidney complicated by alkalinity and casts, its value is acknowledged, and in cases of non-obstructive suppression of the urine and acute nephritis which shows a tendency to chronicity, incision of the capsule by relieving tension and establishing drainage may prevent an acute nephritis from becoming chronic. Some cases of genuine Bright's disease have had temporary improvement from decapsulation, and these were almost without exception cases of parenchymatous nephritis complicated by anuria of renal origin, but with competent hearts. Most of these, he thinks, relapse within a few months. He predicts that the Edebohls operation will be relegated to oblivion to a great extent in the near future.

38. **The Nose and Genitalia.**—Talbot's article calls attention to the nasal symptoms associated with excitement of the genitalia, giving a number of interesting facts from literature and reporting cases of his own observation.

40. **Acetozone in Otology and Rhinology.**—Barnhill notices the value of acetozone in chronic otorrhea, also in sinus abscess, syringing the solution into the sinus after it has been thoroughly opened and curetted. He has also used it in cases of furunculosis of the external auditory meatus and in cases of infection of the follicles of the nasal vibrissæ. He has also used acetozone as an inhalant, by means of a Boeckel nebulizer. This was in cases of laryngeal and tracheal irritation with cough, and from a face shield under pressure of twenty pounds, each treatment covering a period of from five to ten minutes. He is not satisfied yet as to the value of the treatment in the latter group.

41. **Insomnia.**—The treatment of insomnia does not resolve itself into a choice of drugs. Not one has been discovered which, when frequently used, does not demand an increase of

dose. One class of insomnia is that from irritative causes due to cold feet or acroparesthesia; another class is due to toxic causes, alcoholism, nicotinism, gout, Bright's disease, gastrointestinal disorders, etc. He speaks highly of hydrotherapy in most forms of the acute affection when it is not contraindicated, and remarks that the insomnia of alcoholism is one of the worst of all forms to treat. He believes more in hydrotherapy in this condition than in chloral. He has been in the habit of using bromids in large doses in combination with other remedies. He thinks the use of hypnotics in pneumonia very reprehensible except in complicating delirium tremens. The insomnia of the gouty is mentioned, and he has found the administration of commercial nitrate of potash, in 20-30 grain doses dissolved in a glass of water, twice a day, to be one of the best eliminants and reducers of arterial tension in gouty cases, but he does not recommend it where the kidney is affected to the extent of producing albuminuria. Among the psychic causes he includes grief, shock, worry and sexual erethism. Habit insomnia may result from unnatural hours of sleep. Morning insomnia he considers a variety of habit insomnia. Among the degenerative types is the insomnia of senility due more or less to interference with the nutrition of the brain cells. Easily digestible and agreeable food at bedtime is perhaps one of the best methods of treatment of some of the cases. Cases resulting from change of life are mentioned, and the fear of insomnia as a cause of trouble in cases of nervous irritation. He thinks that the seriousness of insomnia is generally over-rated, and that it is consequently overtreated. For the insomnia of the climacteric he has been in the habit of prescribing a glass of hot water at bedtime, to which two ounces of camphor water with 10 or 20 grains of bromid of potash and some tincture of sumbul and hops have been added. Insomnia from pain demands relief from the pain. For this opium is the most effective remedy, excepting in neuralgia, where 10 or 15 grains of phenacetin or a lesser amount of acetanilid are often very effectual. Opium should never be given for the pains of hysteria or neurasthenia. Codein in small doses along with methylene blue is often most effective. Before prescribing the latter remedy he prepares the suggestible mind of the patient by the positive assurance that when the urine appears blue the pains will cease and sleep will come. This is not all purely suggestion, for methylene blue is a decided sedative in some cases. In general pruritus calcium chlorid is mentioned as a valuable remedy which he has used empirically for a number of years, but can not explain its action. In the insomnia of gout he lately has been pleased with erythrol tetranitrate which lowers the high blood pressure.

51 Traumatic Pyeloparanephric Cyst. Bern B. Gallaudet.

45. **Traumatic Asphyxia.**—Beach and Cobb report and illustrate a striking case of this condition resulting from severe pressure on the chest, treated with good results, and they review the literature to some extent, especially the theories as to the cause of the change in color. Microscopic examinations were made of the blue-black skin in this case, and they find from results that the theory of discoloration as being due to hemorrhage is wrong. They are inclined to believe that there were no hemorrhages of any extent whatever into the skin, and that the discoloration was due to a stasis from mechanical over-distension of the veins and capillaries, with or without paralysis, from engorgement of or pressure on the sympathetic nerves. They comment on the great value of artificial respiration after release of the individual from compression, and say it is rational to suppose that the immediate use of artificial respiration and oxygen might resuscitate some cases when it could be applied at once. The cases that live without such aid will always be very rare. The secondary treatment aside from combating shock must be symptomatic.

46. **Spinal Cord Injuries.**—Mixter and Chase report two cases in which degenerative conditions were traced down from the motor tract of the cord. They ask what is the value of operation and answer by saying that it removes the depressed fragments and blood clots; it allows the escape of exudate and makes room for inflammatory thickening; if extensive hemorrhage is present, either intradural or extradural, it relieves pressure and gives space for traumatic spinal edema. There is no other method by which one can diagnosticate slight or great pressure from fragments of bone or large or small hematoma, or determine whether the pressure is constant or temporary. The fact that the cord looked normal in the cases reported does not preclude the possibility that pressure had existed and that drainage and relief were not distinctly beneficial. Patients do not suffer from the ill effects of the operation *per se*, and its dangers are very slight compared with its possible benefits and the knowledge that the surgeon gains that continued pressure does not exist.

47. **Gastroenterostomy.**—The operation of gastroenterostomy and its difficulties are noticed by Rogers, who finds that the operation has been too often one of last resort and that this accounts for the number of failures. Absolute asepsis is unattainable at present in any operation on the interior of the alimentary canal, but infection should be escaped as much as possible. The vicious circle, vomiting, is one of the most common causes of death, and the attempts to avoid it by giving the loop some particular position in relation to its mesentery, its legs, or the stomach or colon, or by making an enteroanastomosis, lead to too prolonged operations, with their numerous dangers and many infections. Experience, however, has demonstrated the necessity of making a fistula as near the greater curvature of the stomach as possible, and also the value of an enteroanastomosis as the base of the legs of the loop. Another result of his experience has been the survival of the Murphy button against all mechanical competitors. Accidents have sometimes happened, but dangerous or fatal vomiting is at least rare, apparently because the button, by nearly filling the lumen of the gut, is a hindrance to sharp kinking or spur formation. Of the other methods not involving any loop, the first is gastroduodenostomy, but gastrojejunostomy is undoubtedly a necessity in the greater number of cases. Roux' Y method has many unpleasant possibilities, the chief of which is the time required and the increased risk of infection. Another operation which does not involve the use of any loop is specially mentioned, that is, the one described by Petersen as used in Czerny's clinic. It is based on the simple anatomic principle that the first few inches of the jejunum lie directly in contact with the posterior surface of the stomach, separated from it only by the non-vascular portion of the mesocolon, and that this part of the jejunum descends vertically and without any turns. The details of the operation are given by the author. Several cases are reported to illustrate the Czerny-Petersen method. From the result of his own experience and from what he collects from others, gastroenterostomy as above described is the most satisfactory operation, and sooner or later it is likely to come into more general use than formerly for chronic, benign gastric disease. The permanency of the artificial opening and its desirability in the presence of a patent pylorus is a problem. It seems necessary to close the pylorus as only under such conditions has experience shown that the new opening will remain patent. The article closes with an extensive bibliography.

49. **Spontaneous Gangrene of the Hollow Viscera.**—Park reports two instructive cases, the most pronounced of any that he has encountered in the literature. The patients in both cases were taken acutely sick. Pain in the abdomen was soon followed by collapse, rigidity and vomiting of coffee-ground matter. An exploratory operation showed very extensive gangrene of the intestines; both cases were fatal. The mesenteric occlusion which is credited with the cause of these conditions

is discussed at length. The more extensive the area the more constant and overwhelming will be the symptoms. Park goes over the differential diagnosis from perforating ulcer of the stomach and duodenum, obstruction, pancreatitis, appendicitis, etc., and remarks in conclusion that in the presence of constant and acute symptoms, including intense abdominal pain, collapse and rigidity of the abdominal wall, very little time should be wasted in speculation as to the character of the lesion. Such cases indicate the immediate necessity for abdominal section. No case that would be lost without operation will be lost in consequence of it, while without it the condition must of necessity prove fatal. Where the patients die under such circumstances they die in spite of operation instead of because of it.

Journal of Cutaneous Diseases, New York.

April

52 Symmetrical Cutaneous Atrophy with the Coincident Development of Syphilis of the Skin and Nervous System. J. A. Fordyce.
53 Case of Chronic Symmetrical Diffuse Hyperemia of the Extremities (Erythromelie). Hermann G. Klotz.
54 *Pityriasis Rosea. Harvey P. Towle.

54. Pityriasis Rosea.—Towle has been able to collect from the records of the dermatologic department of the Massachusetts General Hospital, 158 cases of pityriasis rosea and to add to them from the private records of Dr. J. P. Bowen 44 more, making a total of 202, inspecting the character of the lesions, their distribution, the presence of primitive plaque, the month of the occurrence, the sex, age, the presence of prodromata and accompanying general disturbance, itching, recurrences, race and occupation. In 5 he made blood examination and in 2 histologic examination. From the results of the analyses of these cases he deduces the following: Pityriasis occurs in the two forms, the macular and the circinate, with about equal frequency. It affects most often the trunk and upper parts of the extremities, but is occasionally confined to one part. The *plaque primitive* is not always found. The disease is most frequent in the autumn months and far more common in women than in men. While it may occur at any age, it is more common between twenty and thirty. As a rule, there are no prodromata or accompanying health disturbances, and itching may be present or absent. Recurrences, though rare, do occur. Race and occupation have no influence. The blood shows certain changes which, however, are not characteristic. Histologically the chief changes are in the cutis.

Annals of Gynecology and Pediatry, Boston.

April.

55 *Atypical Appendicitis. Ernest W. Cushing.

55. Atypical Appendicitis.—In some cases of appendicitis the symptoms are so indefinite, especially in women, that it is impossible to make a diagnosis. It frequently happens that mild or masked appendicitis is the cause of suffering supposed to be sufficient trouble in the appendages to explain the symp- advisability of examining the appendix in all operations for obscure pelvic disorder, especially when there does not seem to be sufficient trouble in the appendages to explain the symptoms. If the condition permits, it is wise to remove the appendix: that is, one that is longer, thicker and harder than normal. The hardness is more important than an increase in size. If such appendices were always searched for, there will be fewer cases where the patient is not cured after removal of the uterine appendages. He reports cases and thinks the following conclusions warranted:

> Many cases of obscure abdominal affections are due to appendicitis, although the symptoms are not sufficiently clear to make a diagnosis. The appendix should be examined in most operations for pelvic disease. Operation is indicated in all cases of appendicitis where there is at any time a decided elevation of temperature. The median incision is preferable in old and complicated or doubtful cases, particularly in women.

62 *Cholecystectomy vs. Cholecystostomy—A Plea for the Plaintiff. Maurice Kahn.
63 *Specifics and Specific Methods in the Treatment of Pulmonary Tuberculosis. S. Simon.

62. Cholecystectomy.—Kahn advises this operation in preference to cholecystostomy, claiming that it is no more hazardous and that it guards against further trouble better. He reports a case.

63. Tuberculosis.—Simon reviews the various drugs and the methods of treatment that have been devised for tuberculosis, such as antiseptics like creosote, arsenic, iodin, gaseous enemata, antiseptic oils, intralaryngeal injections and nuclein, the various serum treatments that have been and are being employed, as well as the *x*-rays and the Finsen light. He does not find in any of these a specific remedy for tuberculosis, and does not believe there will be any one specific found. A great deal can be done, however, for the early cases by individual treatment, environment, diet and general hygiene, pulmonary gymnastics and symptomatic treatment with drugs.

Interstate Medical Journal, St. Louis, Mo.

April.

64 *Case of Thrombosis of the Superior Mesenteric Artery. H. G. Mudd.
65 The Clinical Significance of Prolonged Uterine Hemorrhage. J. Wesley Bovée.
66 *Radiotherapy in the Treatment of Acne Vulgaris. (Continued.) Martin F. Engman.

64. Thrombosis of the Mesenteric Artery.—A case is reported by Mudd in some detail, with a partial examination confirming the diagnosis and a general discussion of the literature. The symptoms seem to be pain, vomiting, diarrhea, often bloody, subnormal temperature, abdominal distension, etc. The diagnosis is largely based on the occurrence of intestinal hemorrhage not explicable by other causes. It is frequently impossible and generally only tentative or uncertain. The only treatment is operative, and the question is how much of the bowel can be safely removed. Only exploratory section will tell whether the case is absolutely hopeless or not. In any case, Mudd says, where occlusion of the mesenteric vessels is suspected, or in which for any reason operation is not made, the heart's action should be stimulated in every possible way, bearing in mind that the only hope in such cases is the establishment of the collateral circulation which may enable the affected parts to regain their vitality. He considers the estimate given by Watson of one-sixth of the cases as amenable to surgical intervention as rather larger than the facts warrant.

66. Radiotherapy in Acne.—Engman's paper is concluded in this issue. He remarks that the rays are almost specific in these cases, nothing else meeting the indications so satisfactorily. Relapse is not frequent as under older methods. Acne is not a harmless disease; though not threatening life, it may destroy the enjoyment of it. The dangers of the *x*-ray are not sufficient to overthrow their advantages in special conditions. Of the thousands of cases of acne treated by the rays he has not been able to find a report of a burn of any degree, though undoubtedly such may occur. Any erythema occurring on the face of a patient during *x*-ray treatment should be looked on with suspicion. He inquires as to the reaction of the patient's skin to sunlight, as an indication of their possible susceptibility to the *x*-rays. The first exposure is five minutes with the soft tube. The hair, eyes and eyebrows are protected, and the tube kept nine inches from the skin. Four days later a similar exposure is given; then again in three days, and afterwards in two days. After the initial exposures the rays are used three times a week, the length of time varying from five to ten minutes, with a tube never nearer the skin than six inches, usually eight. In no case does the current exceed two amperes, with the light always at the initial degree. In his 48 cases bronzing occurred once and erythema once during the treatment. He gives a resorcin and zinc oxid lotion for the patient to use on the face several times a day, and he should be cautioned against infection. Atrophy of the skin has been reported, but he does not see how it can occur without some inflammatory symptoms. If undue haste to cure is avoided and mild treatment continued patiently, the danger, he thinks, would be slight.

71 Puerperal Infection. J. F. Jenkins.
72 *Gunshot Wound of the Abdomen—Eighteen Perforations—Intestinal Resection (5 ft. 7 in.)—Recovery. John D. S. Davis.

68. **Influenza in Children.**—This protean disorder may occur in children and be recognized with difficulty. The most common mistake is to take it for an ordinary "cold," but if bacteriologic examinations are made more generally a larger number of diagnoses of this condition will be the result. The treatment Snyder here advises is to put the child to bed in a well-ventilated room, protected from draughts. Calomel is given until the bowels move freely. There should be plenty of fresh air. He then follows Southworth's method for the abortive treatment of inflammation of the cervical glands, which has for its purpose the prevention of further absorption of infectious matter from the nasopharynx. For the fever he gives tablets containing ¼ grain each of tincture of aconite and belladonna with 1/10 grain of camphor; one-half to one tablet every two hours. For the pharyngeal complications he uses chlorate of potash 1 to 2 grains every two hours for twenty-four hours, and then less frequently, and very cautiously watching effect on kidneys. A Seiler antiseptic tablet dissolved in half a glass of water, pouring a little into each nostril every three hours. If the child is old enough he would give an antiseptic gargle. If there is earache he would use 4 grains morphin and 1 grain atropin sulphate, with 15 grains boric acid in one ounce distilled water, dropping from three to six drops into the ear and allowing it to remain for twenty minutes. The diet has considerable to do with the treatment. If the child refuses diluted milk nothing but water is given. In the beginning cases usually do well without nourishment.

72. ***Abdominal Anastomosis.***—Davis reports a case of gunshot wound with 18 perforations of the intestine and resection of five feet seven inches, followed by recovery. He describes the button which he uses and which he thinks has an advantage over the Murphy button, being without a spring. He also has a horseshoe button which he would use for partial opening of the intestine where necessary and for other purposes. Both of these are illustrated.

73. **Colitis.**—Three cases are reported by Henning in which operation was performed, in one of which the appendix was used according to Weir's recommendations, though the author does not mention Weir's publication on the subject. Two cases were entirely successful.

74. **Bronchial Breathing in Pleurisy with Effusion.**—From his observation McCown thinks that where bronchial breathing is associated with extensive flatness on percussion, obliteration or bulging of the intercostal spaces, and fixation of the affected side, he would be *inclined to attribute it to pleural effusion* and not to pulmonary consolidation. If the left side is affected, displacement of the heart's apex would be a strong point in favor of this view.

79. **Pneumonia.**—Brown makes the suggestion of constricting the extremities to cut off return circulation and prevent excessive flow to the inflamed lungs.

1. **Retroversion of the Gravid Uterus.**—The reason why this condition requires treatment, according to Herman, is simply because it leads to retention of urine and its effects. This may cause death by the transmission of the infection from the bladder to the kidneys and ureter. The bladder may give way and extravasation take place. This is not bursting of the bladder, but a perforation by destructive inflammation. Death may take place from peritonitis, and it is commonly stated that when the retroverted gravid uterus is not replaced sloughing of the uterus and a slow discharge of its contents through the rectum and vagina may occur. This Herman doubts and analyzes the reported cases, showing how they were probably ectopic pregnancies and in no case absolutely convincing. The statement as to the danger of abortion in retroversion of the gravid uterus he thinks is without foundation. The treatment is simply the use of the catheter, withdrawing the urine. There is no evidence that retroversion itself has any ill-effect on the organ. Its only importance arises from its ill-effect on the bladder. Keep the bladder empty and the patient recumbent and in over 90 per cent. of the cases the uterus will right itself. If it does not, pregnancy will still go on. The uterus will enlarge, its anterior wall rising in the abdomen to accommodate the growing fetus and the bladder, ureter and cervix accommodate themselves to the altered position and retention ceases. Unfortunately, it has already done harm in many cases. Still, while it is not absolutely necessary, reposition is often advisable. Herman has never seen a case that could not be pushed up. If there is difficulty in doing this by way of the vagina then use two fingers in the rectum under anesthesia. He sees no reason for performing abdominal section in these cases.

4. **The Glycogen Reaction in Blood.**—This reaction has been mainly studied on the continent and in America, and has received too little attention in Great Britain, according to Gulland. The solution which serves for fixing the stain and mounting is composed of iodin 1 gram, iodid of potash 3 grams, distilled water 100 c.cm., with enough gum acacia or gum arabic to make the fluid syrupy. The bottle should be kept tightly corked to prevent the evaporation of the iodin. A rather large drop of this solution is placed on a clean slide and the ordinary air-dried blood films on a cover glass, lowered on to it and allowed to remain undisturbed for half a minute for complete staining and then displaced toward one end of the slide in order that the thick layer of fluid may not cut off too much light in the examination; or the surplus fluid may be removed with a filter paper. The gum soon sets and the preparation will keep for weeks, though it gradually fades. The specimen is at once ready for examination and this must be done with an oil-immersion lens and a good light. In a film of normal blood treated in this way the red corpuscles will stain yellow or white on a faintly yellow background and the white corpuscles of a much finer lemon-yellow tint. The lymphocytes, indeed, can hardly be distinguished except by the slight difference in the refractive index of their nuclei. The eosinophiles can at once be recognized by the high refractive index of their granules and the polymorphonuclear neutrophiles always look darker than the others. In none of these should there be the least trace of red or brown. The above appearances constitute the negative reaction. In the positive reaction the changes occur in the polymorphs alone and the cells affected give a brown or reddish-brown color of glycogen in three ways: as a diffuse color, as a fine granulation and as coarser scattered granules or masses. The nuclei are never affected. The number of cells affected in the positive reaction varies greatly, from only 2 or 3 per cent. to almost all, but, if after five minutes' searching or the passing of 100 polymorphs in review no positive cell is seen, the reaction may be considered negative. The chief diseases in which the positive reaction is constant are croupous pneumonia, bronchial pneumonia, empyema, abscess or gangrene of the lung, septicemia, pyemia of all kinds, all advancing suppurating processes, all septic gangrenes, appendicitis and peritonitis and other conditions of less importance. The conditions in which it is absent are equally important, such as rheumatic fever, chronic rheumatoid arthritis, chorea, rickets, infantile atrophy, congenital heart disease, catarrhal jaundice, tubercle, pleurisy, bronchitis, whooping-cough, asthma, etc. Gulland thinks the method which enables us to approach the greatest certainty in the diagnosis of deep-seated pneumonia and to distinguish gonorrheal arthritis from ordinary rheumatism, septic or cerebrospinal meningitis from the tuberculous variety, cerebral abscess from cerebral tumors, obstructed from strangulated hernia and also which has a wide range of usefulness in septic conditions, deserves a more frequent application than has yet been accorded to it.

6. **Tuberculosis.**—Symes and Fisher have investigated a large number of cases of tuberculosis, separating those under twelve years of age from the older cases. They say:

> If we take local foci of disease as evidence of primary disease in the neighborhood of the foci, our statistics tend to show that during the first twelve years of life tuberculous infection by the air passages is four times as common as by the alimentary canal. Our statistics also seem to show that the comparative frequency of infection through the alimentary canal during the second twelve years is equally common. Deaths in hospitals above the age of 12 years can hardly, however, be taken to represent the average causation of death from varieties of tuberculosis for the whole population above that age, because cases of tuberculosis of the lungs are more chronic than at an earlier period of life, and are not usually admitted to ordinary hospitals.

21 *So-called Intra-uterine Cretinism and Its Supposed Identity with Endemic and Sporadic Cretinism. H. Bayon.

13. **Neurology of Vision.**—The first of Parson's Arris and Gale lectures is devoted to a description and discussion of the anatomy of the afferent visual tract. The author considers that the layer of rods and cones of the retina and its ganglion cells, together with the optic nerve, are a portion of the central nervous system and traces the fibers back by the usual degenerative experiments and clinico-pathologic facts through the optic tracts to the external lateral geniculate body and from this to the region around the calcarine fissure in the occipital lobe of the brain.

14. **Fractures of the Skull.**—Rawling's second lecture treats of hemorrhages; first, the external ones in the ear, nose and orbital region. Aural hemorrhage occurs with a great majority of fractures involving the middle fossæ of the skull, including the region of the external auditory meatus. He thinks too much stress is laid on the fact that hemorrhage from the ear may result from other causes than fracture and regards this symptom when secondary to a blow on the head as diagnostic of this particular fracture of the middle fossa. In some few cases hemorrhage occurs from both ears, the fracture running from one side to the other. The prognosis of these cases is necessarily grave, but the vitality of young adults enables them to recover often even under very unfavorable circumstances. Hemorrhage of the nasal cavities is one of the most constant symptoms in fractures of the base occurring in nearly all fractures involving the anterior or middle fossa. The postmortem lesions are comminuted fracture of the cribriform plate of the ethmoid and of the sphenoidal body. Hemorrhage into the orbital region is described in detail, noticing the subconjunctival and palpebral hemorrhages which, when they occur, usually accompany complications in the orbital region. Proptosis, when immediate and severe, usually indicates a severe fracture in the region of the sphenoidal fissure and cavernous sinus, and when moderate and appearing after a few hours, implies fracture involving the orbital walls with blood derived from lacerated ophthalmic vessels. Third, when appearing days or weeks after the injury and usually steadily progressive, it occurs from fracture involving the cavernous sinus with injury to the internal carotid artery and the formation of fistulous communication between the sinus and the artery. Hemorrhage into the mastoid and occipital region is also mentioned and orbital aneurism, which is usually due to injury to the internal carotid from fracture, traveling along the anterior border of the petrous bone to the cavernous sinus. Internal hemorrhages such as both the extradural and intradural, cortical and intraventricular, are noticed at some little length. Uncomplicated middle meningeal hemorrhage is rare. From his own experience Rawling would put the suggestive symptoms in the following order as to the frequency of occurrence: 1. The appearance of temporal hematoma. 2. Copious and continued hemorrhage from the ear. 3. Twitchings of the facial muscles on the opposite side and twitching or spasm of the muscles of the opposite arm and leg. 4. A brief lucid interval between the states of concussion and collapse. 5. Some alteration in the pupil of the affected side, more commonly the "constricted" pupil. Early trephining is important and the mortality in cases operated on is very much less than in cases left alone. It is better to operate and to find no hemorrhage than to neglect it until too late. He thinks it advisable to tie the external carotid in preference to the common carotid, as the more extensive interference with the blood supply may cause serious cerebral changes. Two cases of severe laceration of the internal carotid are mentioned where death was almost instantaneous. The subarachnoid and subpial regions are also noted, as well as intraventricular hemorrhage, with symptoms similar to those of apoplexy. The escape of cerebrospinal fluid from the ear is so much spoken of in the text-books that it is supposed to be of common occurrence, but that is not Rawling's experience. It does not materially affect the prognosis. Large quantities may be lost without any striking effect, and the danger of infection does not appear to be increased proportionately, as the outflow tends to wash away the micro-organisms present in the external meatus. It is inadvisable in these cases to syringe out the ear, and the meatus should be merely swabbed out with some strong antiseptic. Frequent changing of dressings may be necessary when the discharge is profuse. When the fluid escapes into the nose little can be done to prevent infection. Meningitis is a common result of fracture of the anterior fossa with this symptom.

15. **A New Chronic Neurosis.**—The title of Monro and McGregor's paper explains the principal symptoms of the case. The authors think the disease is a neurosis allied on the one hand to angioneurotic edema, though on the other presenting points of resemblance to the purpuric type of erythema. They are inclined to consider the hemorrhage as due to a neurosis rather than to an infection. In their case the only treatment that seemed to do much good was counter-irritation in the form of a seton in the back of the neck.

19. **Cancer.**—Plimmer analyzes 17 cases treated with radium bromid and concludes that emanations from this substance can only act on young and rapidly-growing cells and that the older cells, especially if surrounded by fibrous tissue, are less and less easily affected, and, if there is an excess of fibrous tissue, hardly affected at all.

21. **Congenital Cretinism.**—Bayon argues against the occurrence of so-called congenital cretinism. The condition of chondrodystrophia fetalis considered by Virchow as an intrauterine cretinism is, he thinks, quite different. The defect or destruction of thyroid glands produces the true cretinism, causing general arrest of development and myxedema, both of which symptoms are absent in chondrodystrophia fetalis where we find simply short arms and legs, probably following inflammation of the cartilages during intrauterine life.

30 A Further Series of Cases of Perineal Prostatectomy. H. L. Maitland.

25. **Ectopic Gestation.**—Worrall reports four cases of ectopic gestation observed during 1903, in all of which the position of the corpus luteum and the condition of the ovaries were noted. In two there was every evidence that the ovum came from the ovary of the side opposite to that of the gravid tube, the ovaries being cystic or atrophied on that side, while on the other a large fresh corpus luteum was found. In the other two cases the ovum on the gravid side contained no corpus luteum while that in the opposite side contained a large fresh corpus. In one of the cases also the fimbriated end of the tube on the gravid side was occluded.

35. **Tardy Liver Abscess After Tropical Dysentery.**—Pel relates the particulars of a case which establishes that it is possible for a liver abscess to develop consecutive to tropical dysentery although the subject may have long left the tropics and an interval of twenty years may have elapsed.

36. **Influence of Drugs in Inducing Immunity.**—In this concluding portion of their communication (see page 1190 in last issue of THE JOURNAL) Ehrlich and Shiga state that the benefit derived from trypan red was not so marked with rats and other animals as with mice, and that hundreds of other stains and drugs were tested without success. Further tests to explain its action apparently demonstrate that the trypan red has no direct influence on the parasites, but it induces a reaction in the animal body which entails the destruction of the parasites. The reaction is transient and ceases in a few days as the stain becomes incorporated with the organs. Further experiments showed that the active immunity conferred by the destruction of the parasites by the trypan red lasted for twenty to thirty days and then gradually subsided. The dead trypanoso-

mata killed by the stain evidently induced in turn the formation of immune substances This reaction ceases as the dead trypanosomata are eliminated and the animals become susceptible anew to fresh infection Residual parasites lurking in the body are held in check as long as this reaction or active immunity lasts, but as soon as the period of active immunity is past they resume their pathogenicity. Observation of these facts suggests an explanation for the recurrences in malaria and syphilis Relapses are due in all these affections to the subsidence of the reaction and the consequent release of lurking residual germs from their latent state The exact duration of the period of active immunity could easily be determined by the length of time during which repeated inoculation proved inoperative and the moment when it began to cause infection The above experiments are interesting, further, because they throw light on the therapeutic action of drugs The trypan red in itself does not kill the trypanosomata, but it induces conditions in the organism which destroy them and lead to active immunity It is possible, Ehrlich concludes, that a cure by chemical agents may afford conditions more favorable for the realization of immunity than those that follow the use of specific serums The serums monopolize a certain part of the receptor apparatus of the parasites and this part is thus excluded from active participation in the production of antibodies

63. **New Route to Rear Surface of Right Lobe of Liver.**—Israel's patient presented a clinical picture suggesting tuberculosis of the right kidney, but the pain on pressure of the lumbar region could be explained only by assuming that the kidney pressed on some diseased organ below. Israel, therefore, made an incision from the rear and pushed the kidney aside, after resection of the twelfth rib. The kidney was mobilized by slitting the capsule and mobilizing the pedicle, pushing the organ aside as if it were a naturally wandering kidney. This exposed the rear aspect of the right lobe of the liver, where a tumor was found and removed, followed by iodoform-glycerin injections through a tube left for the purpose, and iodids internally. Recovery was rapid. The tumor proved to be a gumma, but the question as to the advisability of surgical intervention in such a case does not alter the advantages of this mode of reaching this part of the liver. It is indispensable that the pedicle of the kidney should be long and elastic enough to permit of pushing the organ aside out of the way.

64. **Treatment of Myoma of Uterus.**—Pfannenstiel emphasizes the necessity of strict individualization in treatment of myoma. The primary prognosis of myotomy would then reach that to which we are accustomed for ovariotomy. Including the unfavorable cases the mortality for both is about 4 to 5 per cent. We are justified in extending the indications for operative treatment of myomata beyond what has been hitherto accepted, and operate on them earlier than has hitherto been deemed advisable. Unless certain that the fundus and cervix are aseptic the vaginal route is preferable. He does not advise abdominal total extirpation except for malignant complications or extremely large size or large infected growths. He thinks it is of the utmost importance to retain the ovarian function before the menopause. The best time for operative intervention is the postmenstrual period. He recommends ablation of all rapidly growing tumors for fear of sarcomatous transformation, of all complicated cases, of deep-seated, eccentrically developing myomata on account of the danger of compression of the urethra or veins, of submucous myomata, and, in short, of all causing disturbances of any kind.

65. **Biology of Tumors.**—In this communication from Olshausen's clinic Saul illustrates the findings in researches undertaken to study the formations found in tumors which some regard as elements of the growth and others as parasites. Five illustrations of the various elements suggesting parasites are given and their history traced. He agrees with Ribbert in denying their parasitic nature.

69. **Treatment of Otitis Media.**—Heine reviews the various methods of treating affections of the middle ear at present in vogue, and in particular those employed at Lucae's clinic in Berlin. Simplicity is the rule there, the aim being to rest the injured, inflamed organ and provide ample outlet for the secretions, as he describes in detail.

73. **Obstetrics in the Homes of the Poor.**—Frank argues to prove that the family and home are the bulwarks of the state, and that if the husband wishes to keep his wife at home during her confinement and she wishes it also, it is the duty of society to render it possible and safe. By the co-operation of physicians with the undergraduates of the training schools for midwives and the charitable organizations, it has been possible to conduct 4,354 childbirths in the homes of wage-earners in his city, Cologne, with temperature in only 7.14 per cent. of the cases. The total includes 45 twin and 2 triplet births. Forceps had to be applied in 2.2 per cent. of all cases, and placenta previa occurred in 11 instances. The placenta had to be manually removed in 67 cases, and there was prolapse of the cord in 24 and laceration of the perineum in 137 instances. There were only 6 deaths and 3 were due to progressive eclampsia or peritonitis after laceration in case of deformed pelvis or to hemorrhage from rupture of an old cicatrix in the cervix. The three other deaths might have been prevented if a physician or midwife could have been found in time—the husband was unable to find either until too late by several hours. Frank thinks that this remarkably fine showing confirms the feasibility of home confinements even for the very poor, and hopes to see the present arrangements at Cologne perfected by the establishment of some central office where the undergraduate midwives or physician can always be procured, day or night, under the supervision of some experienced obstetrician. The services of the midwife must be remunerated—at a minimum rate of $4. Charitable organizations must assume the task of supplying suitable food and bedding and keeping the household going, while medicines, dressings and disinfectants should be supplied free by the municipal hospital administration.

78. **Experimental Decapsulation of Kidney.**—Thelemann reports extensive research on dogs which has established that the new capsule forms from the relics of the old and the septa penetrating the parenchyma. The decapsulation has no unfavorable action on the renal parenchyma, but neither is it more than transiently beneficial. He was unable to discover any increased formation of blood vessels. Merely the former anatomic conditions were reproduced, and consequently he doubts whether the procedure can be of permanent benefit to man. He thinks that the clinical results published to date are not free from objections. The severe cases operated on by Edebohls have died; the milder cases have improved and some of them have completely recovered. It is still an open question whether they would not have recovered equally well without the operation. The chloroform narcosis is also a disadvantage that must be taken into account.

79. **Statistics of Mammary Cancer.**—Schmidt states that at the Göttingen clinic 211 patients with cancer of the breast have been operated on. Of this number news has been received of 109 after an interval of at least three years. In 77 cases there has been recurrence, and 32 of the patients have been permanently cured, with intervals as long as ten and fifteen years in some instances. This gives a proportion of 28.32 per cent. of cures.

80. **Extraperitoneal Transplantation of Uterus After Enucleation of Myomata and as Treatment for Prolapse.**—The motives for this new mode of surgical intervention are enumerated by Kocher as follows: 1, possibility of immediate, direct visual inspection, rendering control of any after-bleeding much easier and more effectual; 2, the greater certainty of an aseptic healing, and the lesser danger of complications on return of menstruation; 3, the operation is rendered much easier, and 4, the procedure is certain and entails the minimum of mutilation in old inveterate prolapse with the simplest of interventions. A further advantage is the relief of pressure and dragging on the intestines, and the favorable influence on the frequent obstinate constipation. The operation has been performed in 5 cases after enucleation of myomata through the abdomen and also in 3 cases of prolapse of the uterus. The menses recur regularly, less profuse but without disturbances of any kind. The remote results of the operation have been in every instance highly satisfactory. The technic of this exohysteropexy, as Kocher has named it, is for prolapse a median incision in the Trendelenburg position. After the fascia and peritoneum have been slit the uterus is pushed up from below and is seized and pulled out through the wound. The peritoneum behind it is then sutured above and a short distance below the uterus, thus leaving the latter almost entirely outside the peritoneum while the ovaries remain inside the abdominal cavity. The suture in the peritoneum must be divided above and below the uterus in such a way as not to interfere with the expansion of the bladder. Towards the sides the parietal peritoneum is fastened to the body of the uterus with a few button stitches. After which the fascia is drawn together over the uterus its entire length and closed with a continuous suture. If there is no oozing of blood drainage may be dispensed with, but otherwise a drain tube may be introduced above and below the uterus down to the peritoneum (thin narrow glass drains are preferable). The operation concludes with a continuous suture of the skin and xeroform gauze and collodium dressing. The intervention varies somewhat from this technic in case of fibromyoma operations. After enucleation or excision of the tumor and suture of its bed in tiers, covering it over with serosa, the body of the uterus (or the stump left), is drawn vigorously for-

ward into the abdominal wound and the parietal peritoneum is sutured above and below behind it with a continuous suture. The button sutures are also applied on each side as by the preceding technic, including the parietal peritoneum and the serosa of the uterus. The fascia may be included also in this suture to insure hemostasis, thus bringing the body of the uterus directly under the skin. This was done in some cases while in others the fasciæ were allowed to close over the fundus uteri with the exception of a small spot (the size of a five-franc piece) through which a tampon was inserted down to the peritoneum. The incision in the skin was then closed with a continuous or button suture with dressing as above. Even in these cases it is possible to suture the fascia over the body of the uterus, thus obviating any secondary hernia. The simplicity, ease and solidity afforded are strong arguments in favor of this new operation. The uterus in time is liable to gradually subside back into normal position. In the first 2 cases sufficient play was not left for the bladder and consequently there was slight, transient disturbance consisting in increased desire to urinate. This was avoided by fastening the uterus a little higher up. No subjective disturbances of any kind nor abnormal sensations were noted in any instance. Menstruation recurred regularly, although less profuse than before and there was no discharge after the operation. The results of the intervention were in every instance highly satisfactory, as confirmed by later examination. The operation was first performed in February, 1902, and all but 2 of the patients were operated on in that year, the others in February and April, 1903. This article has been ready for publication for nearly a year, but Kocher has waited for the remote results. The only possible objection to this operation is pregnancy later. If it should occur—which is seldom observed after a myomectomy—it would be very easy to enlarge the opening enough to release the uterus. No damage has been done to its nerves or blood vessels by the exohysteropexy, and there has been no occasion for the formation of adhesions. It thus avoids all the drawbacks of ventrofixation.

81. **Filling Bone Cavities.**—Brüning describes the history of bone plugging or filling—to use the dentists' phrase—and states that Merrem in Giessen was the first to reimplant fragments of bone. Of all the various technics he prefers that of Mosetig, described in these columns, xl, pp. 881 and 1544. It shortens materially the time of treatment, patients leaving the clinic, able to use the leg, two to three weeks after removal of a sequester from the tibia. Unfortunately the method can not be applied unless the cavity can be completely smoothed and cleaned, which is not always the case.

83. **Alcohol Compresses for Relief of Pain.**—Amrein describes the remarkable relief afforded by local application of alcohol in appendicitis and spondylitis tuberculosa, as also the rapid retrogression of inflammatory processes under alcohol compresses.

84. **Sanoform as Dressing for Wounds.**—Burchard lauds sanoform as at least fully equal to iodoform in every respect while free from all the disagreeable properties of the latter.

86. **Holoptic Method of Studying Anatomy.**—Ponfick thinks that the study of pathologic anatomy should proceed on broader lines than those hitherto adopted, and should aim to discover more than the one organ involved in the disease process. Its manifold relations to the neighboring parts should be systematically studied before the organ is taken out for closer examination. He calls this the holoptic method as opposed to the current metoptic, that is, inspection of the whole instead of a part. After the cadaver is frozen it is possible to make a "frontal" section which will expose the conditions induced by a left pneumothorax, for instance, the section leaving the lung intact, and the accumulations of gases and fluids still *in situ*. He gives an example of this kind in a colored plate, and points out a number of new points that can be learned from this general oversight of the conditions, both the direct and indirect results of the lesion.

87. **Operative Grafts of Echinococcus Cysts.**—Madelung describes a case in which there was recurrence of the cysts two years after extirpation. The circumstances showed that the recurrences were due to scraps grafted into the abdominal cicatrix. As a preventive measure he endorses Dévé's proposal to inject an equal amount of some fluid to kill the parasites after evacuation of the cyst contents by puncture. It should be given plenty of time to exert its destructive action, and then it should be siphoned out and the sac extirpated as usual.

88. **Injury of Heart from Violent Bending Forward of Trunk.**—In the 2 cases described the trunk was bent stooping forward by a traumatism. In one the woman fell over backward, turning a somersault. There were no signs of direct injury of the heart region, but symptoms of acute dilatation of the heart followed. In one case there was soon complete restitution, but in the other and in a third case myocarditis ensued. The findings parallel those of acute dilatation from overexertion, but differ as the dilatation is due not to increased arterial pressure, but to compression of the air in the thorax by the obstruction to the outflow of the venous blood. The details of a case of acute dilatation in consequence of muscular over-exertion are given for comparison of the two conditions.

89. **Head Tetanus.**—Grober's experience of tetanus includes 13 cases, and indicates that the longer the incubation the milder the course. In the case of head tetanus the patient was a man of 46 who had at one time been subject to epileptic seizures. The tetanus followed an injury of the brow, and was complicated by paralysis of the facial nerve, which persisted after recovery from the tetanus. The benefit of antitetanus serum was marked in this and the other cases. Grober believes in giving as much of it and as often as possible.

90. **Scoliosis Consecutive to Sciatica.**—Ehret presents further arguments and illustrative cases to sustain his theory that the scoliosis observed after sciatica is due to the position of the leg maintained by the patient in order to relieve the pain, with compensation on the part of the spine to render it more comfortable. In all cases of sciatica, therefore, attention should be paid to the spine and a fixation cast applied in rebellious cases in the endeavor to prevent spinal deformity later. The water-glass cast should extend from the toes to the hip, and keep the limb in the primary, not compensated, "self-relief" position. He has been able by this means to ward off impending scoliosis in 14 cases. When the self-relief position is only slight it can be maintained with cushions and compensation on the part of the spine thus be avoided. He keeps the cast on for ten to twenty-one days. When the scoliosis is once established from sciatica—even long past—much benefit can be derived from permanently raising the height of the sole on the affected side. With an inner sole 3 cm. thick, he succeeded in eighteen months in completely curing a pronounced scoliosis left from a sciatica nearly five years before. The particulars of 5 cases are given in detail, the patients 28 to 46 years old, with diagrams to show the mechanism of the developing scoliosis.

91. **Liver Abscess.**—Koch analyzes his experience with 16 cases, pointing out the differentiating points and urging prompter surgical intervention.

94. **The Larynx and Pulmonary Tuberculosis.**—Frese reports from von Mering's clinic at Halle the results of inoculation of the larynx in dogs with human tuberculous sputum rubbed directly on the larynx wall. The dogs proved unusually refractory to infection with human tuberculosis, but it was ossible to induce in this way a tuberculous affection of the rynx. The findings have convinced Frese that laryngeal uberculosis must be generally of sputogenic origin. The sites where it located in the dog corresponded exactly with what is observed in man, and show that the movements of the vocal cord press the sputum material into the mucosa of the larynx. The parts protected by ciliated epithelium and by the secretion of its glands usually escape unless some injury favors infection.

95. **Senile Osteomalacia.**—At the necropsy of the case described by Schiffmacher the skull cut like cork or rubber, and the ribs could be bent in any direction. The subject was a woman of 67 who had manifested signs of senile osteomalacia during the last ten years of life. The diagnosis was confirmed by the softness and misshapen aspect of the bones and the development of much osteoid tissue free from lime. Such cases coincide in every respect with other cases of non-puerperal osteomalacia, and a sharp distinction should be drawn between them and ordinary osteoporosis.

96. **Means of Testing Therapeutic Measures in Cord Affections.**—Büdingen gives an illustration of an apparatus which he calls a reflexometer. The subject sits in a very high chair and the knee-jerk is elicited by a mechanism which graphically registers the response. In this way the benefit derived from treatment may be ascertained from time to time, and functional be distinguished from organic affections. The apparatus has established that the reflexes are unaffected by galvanism, showing that the galvanic current passing through the spinal cord has no stimulating effect on it.

98. **Injection Treatment of Gonorrhea.**—Lucke's experience has shown that persons who develop posterior urethritis during the first fourteen days after gonorrheal infection are almost exclusively cases of repeated infection, while those infected for the first time do not begin to show traces of posterior involvement until after the third week. It is necessary, therefore, in treatment to distinguish between the first and multiple infection. The sphincter urethræ externus in cases of repeated infection is liable to become more or less impaired and incompetent. For this reason he thinks that these cases should not be treated with injections under pressure and long retention of the fluid. The same applies also to cases of first infection after the third week.

99. **To Ward Off or Destroy Mosquitoes.**—Forel writes feelingly on the subject of the necessity of protection against mosquitoes since a trip to tropical regions a few years ago. He suggests the feasibility of sending some physician to a region infested with anopheles—avoiding malarial regions—and have him test on his own person various kinds of drugs and substances until he discovers one that will kill or drive away mosquitoes while harmless to the bearer. He suggests that the investigator might expose one arm smeared with the substance to be tested, while the rest of his body was protected by a mosquito net. It might be possible in this way to discover some substance which would drive away mosquitoes entirely from persons carrying it. He refers to the fact which he has himself corroborated that certain ants can eat large quantities of arsenic with impunity while flies rapidly die after eating a small amount. He also refers to the fact that the myrmicinæ, a kind of ant, lose their powers of smell after their haunts have been strewed with sublimate, and they then turn and rend each other, the members of a single colony thus exterminating each other, the same as when the tips of their antennæ are cut off. He thinks that it may be possible by some similar action on the mosquito's sense of smell to make him keep his distance from man.

102. **Gaertner's Tonometer.**—A description of this instrument was given in The Journal, xxxiv, page 415. Gaertner here passes in review all the articles that have been published in regard to experiences with it in the hands of others as well as his own—a total of nearly forty-three articles. His final verdict is to the same effect as his earlier announcements, namely, that the tonometer shows up well the variations in the arterial tension, and is a convenient instrument, thus establishing its value for clinical medicine. Thanks to these properties it is entering into general use with uncommon rapidity.

104. **Anesthesia of the Spinal Cord.**—Bier, the rediscoverer of spinal anesthesia, protests against this name and reiterates that it is strictly an anesthesia of the spinal cord. He always protested against its general adoption, claiming that the procedure was still in the experimental stage and liable to prove dangerous. He now announces that the introduction of the suprarenal preparations has placed it on a safe basis. Their use renders it possible to insure strict localization of the cocain at the point where its action is desired. Dönitz first established that adrenalin injected into the lumbar sac is tolerated by small animals even in amazingly large amounts. It was then applied in the clinic in cases in which general anesthesia was contraindicated, if the patients expressed a willingness for its use. A total of 121 patients have thus been submitted to suprarenin or adrenalin-cocainization of the spinal cord. The patients' ages ranged from 16 to 80; all but 22 were men. Adrenalin was used in 56 cases and in 5 instances no anesthesia was induced, while suprarenin failed 6 times in the 65 cases in which it was used. The patients were all extremely debilitated or suffering from serious affections which contraindicated general anesthesia. Not a single mishap occurred in any instance. The anesthesia did not extend so high as when cocain is used alone, which further demonstrates its localization. It was necessary to make the injection higher up when the operation was above the buttocks region, between the second and third lumbar vertebræ. The anesthesia extends higher up when the pelvis is raised a little.

but caution is necessary when this is done, and further experience to determine the safe limits. It has been found possible to induce anesthesia in dogs over the entire body, including the head, with lumbar cocainization. Bier has the patient lie on the table, the upper part of the body raised, the spine curved, humping outward. A line drawn to connect the two crests of the ilium crosses the fourth vertebra. The forefinger is then carried from its spinous process to the process above and beyond it until it is in the interspace above, between the second and third lumbar vertebræ. The needle is then introduced into this interspace on the convex side of the spine, the side toward the table, and about 1 cm. to one side of the finger. The needle is readily pushed up and in. The injection is not made until the cerebrospinal fluid appears. If it spurts in a jet it is advisable to allow a few c.c. to escape. The syringe is then attached to the needle and the adrenalin or suprarenin injected. The syringe left attached to the needle closes the opening. After waiting for five minutes to allow the suprarenin or adrenalin to get in its work, the cocain is injected from a second syringe. In ten minutes the patient is ready for the operation. The whole procedure is very simple, much more so than general narcosis. It can be done by an assistant in the anteroom and during the fifteen minutes of waiting he can be preparing the field for the operation. The Quincke needle is used, with two well-fitting syringes. The solutions are made as follows: .5 c.c. of the Höchst 1:1000 solution of suprarenin is mixed with an equal amount of physiologic salt solution and boiled up briefly before use. The whole amount is then injected. The cocain is prepared by dissolving .1 gm. in 10 c.c. of sterile physiologic salt solution. The amount of the solution needed for the day is sterilized by boiling. From .005 to .02 gm. of cocain in a 1 per cent. solution is the dose. Alkalies precipitate the cocain base in the needle, and consequently the syringes must not be boiled in soda water, but in pure water. The needles are boiled in a soda solution, kept in alcohol and syringed through with saline just before they are used. The physiologic salt solution is preferred by Bier, as he could not discover any advantages from solutions isotonic for the cerebrospinal fluid. He thinks that failures to obtain anesthesia may be avoided by using fresh solutions of cocain and not injecting the fluid until the cerebrospinal fluid is dropping rapidly from the needle. The needles must not be too long, and the tips should not be slanting, as in the latter case the cerebrospinal fluid might flow out through it while only part of the tip was in the sac, and injection of the cocain might distribute some of it through the neighboring tissues. Of course the dose of cocain must be sufficiently large. On the whole, Bier proclaims that by the new technic the real dangers of spinal anesthesia are obviated. It is extremely important, moreover, that elderly and debilitated subjects tolerate the procedure remarkably well. It is further remarkable that elderly subjects very seldom exhibit any of the disagreeable by-effects. Bier has derived the impression from his experience that these by-effects are on the whole much reduced by the addition of suprarenin or adrenalin, but they are still bad enough. In 27 out of the 56 cases in which adrenalin was used he observed an outbreak of sweat, vomiting and tremor of the muscles during the anesthesia and afterward, as the most regular and distressing phenomenon, headache with sometimes vomiting. The remaining 29 were entirely free from these by-effects. Sometimes the headaches were very intense and persisted a week. Slight rise of temperature was frequently noticed, but never the high degrees and chill noted with the older technic. In a few cases there were transient retention of urine and stiff neck, the former possibly due to the surgical intervention on the pelvis. The same by-effects were noted with suprarenin, with the difference that the symptoms of irritation, retention of urine and rigidity of the back of the neck were rare and slighter. A swiftly transient paralysis of both peronei was noticed in one case. Bier is convinced that the suprarenal preparations act as antagonists to the dangerous action of cocain in spinal cord anesthesia. The list of cases in which he has applied the combination includes 9 cases of amputation and resection of the rectum according to Kraske; 8 of amputation above or below the knee; 1 of Edebohls' decapsulation of the kidney (bilateral); 3 of resection of the hip joint; 11 operations for hemorrhoids and 1 of prostatectomy. Those of the patients who had previously undergone general anesthesia were asked as to which technic they preferred and the majority decidedly favored the spinal cocainization, while others preferred general anesthesia, and one patient declared they were both equally horrible.

106. **Doubts of Existence of N Rays.**—Graetz states in the course of this review of recent research on the Röntgen and radium rays and the N rays, that the existence of the latter has not been corroborated by any observers in Germany. He rather doubts their actual existence, as he spent a two weeks' vacation in endeavors to elicit and detect them to no avail. The brightening of the luminosity of faintly luminous bodies is a subjective phenomenon which may be due to other causes than an actual heightening of the luminosity. Lummer has recently pointed out a source of error in this connection. He showed that the visual impression of a faintly luminous body depends on the alternating supremacy of the rods and cones in the retina. The fovea with which we see directly consists solely of cones, while the peripheral portion of the retina contains both cones and rods. The rods do not distinguish colors, but their sensitiveness to light is greater than that of the cones which are sensitive to colors. Consequently, in a dark room we see the faintly luminous small body at first with the rods, peripherally. When we fix the spot at which we are looking, and thus look at it with the cones, there is less perception of light as the cones, with which we then are seeing, are not sensitive to light. With a stronger but still dim light we will see more luminosity peripherally than central. Blondlot noticed that whenever the hand or a piece of lead is interposed between the source of the N rays and the faintly luminous reacting body, that the latter became darker. This is due to the fact that in so doing he unconsciously fixed the reacting body and thus it appeared less luminous, while as soon as the axis of the eye ceased to bear on it directly, the luminosity of the reacting body was appreciated once more at its true value. Graetz admits that this explanation does not cover all the phenomena which have been reported in regard to the N rays, but adds that as long as they can not be reproduced by other observers they can not be ranked as an acquisition to science.

107. **Remote Results of 900 Gallstone Operations.**—Kehr announced two years ago that he had found as the remote results of a series of 400 laparotomies for gallstones that stones had been left behind in 4 per cent. of the total number; hernia had developed in 7 per cent.; adhesion colics had been noted in 11 per cent. and inflammation colic in 6 per cent. The results in a later series of 500 similar operations have been considerably better. Seventy-two out of 450 died in the clinic, but in only 3 instances could the gallstone operation be incriminated in the fatal termination. Since leaving the clinic 21 have died, mostly from cancer. Of the remaining 357 he received answers from 350 to the question blank he sent out. He found that stones had been left behind in 9 cases, that is, in 2.5 per cent. In 5 of these cases he had intentionally refrained from further search on account of certain prohibiting circumstances. In the 4 cases in which the stones had been inadvertently left they were always in the common bile or hepaticus duct. In 3 of these cases the stones have since been passed and the patients seem permanently cured. Once he performed a second operation for the removal of a stone. He proclaims with emphasis that in his entire series of 900 operations he has never encountered a regrowth of stones. Out of the 350 subjects one has still a mucus and one a bile fistula. In the first case the stone was left knowingly in the cystic duct on account of the great depth of the latter. The bile fistula occurred after drainage of the hepaticus, the patient leaving the clinic before Kehr was satisfied that the bile duct was entirely free. Hernia has occurred in 3 per cent., and only in the cases of severe suppuration requiring extensive tamponing, with return to hard labor soon afterward. Adhesion colics have been noted in 12, and inflammation colics in

5 instances—a total of 5 per cent. In 11 of these 17 there had been previous major abdominal operations so that he does not know to which to attribute the adhesions or inflammations. In 3 the colics were traced later to stones in the kidney. Hence we see *that* 89 per cent. of the 350 are completely freed from all disturbances and only 11 per cent. have anything to complain of. His question blank contains the following questions:

1. What is your present health?
2. Have you ever had colics since as before the operation? Or pains in intestines or stomach? How often, since when? Where were the *pains located*? Please describe them exactly.
3. Have you a fistula in the scar (*a*) mucus fistula, (*b*) bile fistula? Does this fistula disturb you?
4. Have you ever had icterus, if so, how long and with or without pains?
5. Have you hernia in the scar? Is the scar hard or soft, does it protrude when you cough? Have you any discomfort from it and what? Do you wear a truss, and what kind?
6. Have any stones passed since the operation? How large, how often? (Please send me the stones if you have them on hand.) What did they look like? Did the physician recognize them as gallstones?
7. What other remarks have you to make? (Work, digestion, increase in weight, childbirths, etc.)
8. *As I regard the opinion of your physician* as of great importance I would be grateful to him if he would express here his opinion.

109. **Prophylactic Sterilization of Women.**—Cramer critically reviews the various methods of insuring sterility and expresses decided preference for steam cauterization of the uterus as by far the simplest and easiest. He has applied it in 5 cases, as he describes in detail, and the results have been the complete involution of the uterus with no further menstruation in some and slight menstruation in others, with no disturbances in either group. This simple method of vaporization is particularly indicated in the severe cases for which alone prophylactic sterilization is justifiable. A single application of the steam was sufficient in some instances, in others two were made. The temperature of the steam was 110-106 C., applied *for one minute, nine days later the steam at* 109-104 C. for two minutes. He treated his last patient with a single application at 115 C. for one minute.

110. **Methylene Blue in Urinary Diagnosis.**—Fischer extols the valuable information to be derived from ingestion of methylene blue in many cases. It renders the cystoscope pictures extremely distinct. A very small amount is sufficient, 0.1 gm. in a capsule internally or .05 gm. in an aqueous solution subcutaneously. No inconvenience has been observed from ingestion of as much as .25 gm. to .5 gm. The latter is the usual dose he employs, given about two hours before cystoscopy. In a recent case he had occasion to drain a tumor which simulated a pancreatic cyst, although the fluid issuing from it showed no characteristics of pancreatic secretions nor any odor of urine. Ingestion of a small amount of methylene blue *stained it exactly the same tint as that of the urine*, demonstrating its nature as a hydronephrosis.

111. **Phototherapy *After Sensibilization*.**—Halberstaedter denounces as incorrect our current discrimination of chemically active and chemically inactive rays of light. In photochemistry the law has long since been established that those rays alone exert a chemical action on a body which are absorbed by the body in question. He reverses this law and proclaims that all rays of the spectrum are chemically active when they are absorbed. The only difference between them is the power of absorption of the articles on which they fall. This power of absorption can be artificially created or magnified, as the photochemists have long known. He has been testing a number of the substances used in photochemistry to confirm Dreyer's announcements in regard to the enhanced action of phototherapy when the tissues *have previously been* sensitized with some substance. His conclusions corroborate those of Dreyer, who found that erythrosin is the most powerful substance for this purpose, for which also its harmlessness eminently adapts it.

116. **Phlegmon After Injection of Adrenalin and Cocain.**—Aronheim reports a case of extensive phlegmon which developed at the spot of injection of a mixture of adrenalin, cocain and saline, previous to amputation of a toe.

119. **Malignant Edema.**—Lotheissen remarks that the treatment of malignant edema and of gaseous gangrene should be the same although the two affections differ in many points. Excision into sound tissue is the rule when the process is still localized. In a case described, the application of hydrogen peroxid probably helped to *limit the process during* the two days that elapsed before the patient's consent to amputation could be obtained. The gangrene of the muscles already involved is not affected by this remedy, but the process remains localized to the spot, which is in itself a great gain. It should be applied energetically, continually dribbling the wound with it, possibly combined with subcutaneous injection. This case is the only one on record of bacteriologically confirmed malignant edema in which it was systematically applied, and even here *not* subcutaneously. Enucleation at the shoulder was done in this case and in time to remove the bacillary focus of the malignant edema. There is still suppuration in the wound, but merely a creamy pus such as accompanies staphylococcus processes, without indication of gangrene or edema. If the focus is located on the trunk the prognosis is bad, as *the hydrogen peroxid is successful only when combined with* amputation. The prognosis is also rendered graver by a debilitated condition. Only 8 recoveries are on record in 23 cases of gaseous gangrene reported of late and amputation had been performed in 6. The prognosis is not much better for malignant edema, and no recovery is known without amputation of the part affected. One died in the 4 cases he cites. *A bacteriotherapy may prove possible and Tavel has succeeded in obtaining an experimental preventively effectual serum from* immunized animals. Owing to the rarity of the disease it would be impracticable to keep a serum on hand and it would take too long to prepare one.

121. **Treatment of Tuberculosis of Kidney.**—Hofmann's first patient recovered complete health after resection of the tuberculous right half of a horseshoe kidney. The second patient was also cured by extirpation of a tuberculous wandering kidney. The symptoms in this case had been attributed to the movability of the kidney and catarrh of the bladder, but the cystoscope revealed pus issuing from one ureter and the presence of small ecchymoses in the otherwise intact bladder mucosa. Pain when walking, subsiding when seated, was another symptom which had been referred to the wandering kidney.

Address.

THE TWO SCIENCES, HUMANITY AND MEDICINE.*

I. A. McSWAIN, M.D.
PARIS, TENN.

In the year 1830, in the month of May, the leading physicians of this state met in the city of Nashville and organized the "Medical Society of the State of Tennessee," and wrote on their escutcheon, "The Science of Medicine an Important Department in the Science of Humanity." After the lapse of seventy-two years, at the reorganization in Memphis, and the adoption of the new constitution, the name was changed to that of "Tennessee State Medical Association," but the motto remained unchanged. It is well. Truth changes not. Time and progress have wrought changes innumerable within the last three-quarters of a century, which corresponds with the life of this association, but have only added emphasis to the truth contained in this motto.

The thought occurred to me to say something on this occasion in regard to the relationship of the science of medicine to the science of humanity; hence the adoption of this motto, in slightly abridged form, as the title of this address.

Science, in its most primitive sense, is to know. To know medicine involves the science of humanity. To know humanity is, therefore, fundamental to medical science, without which medicine at once ceases to be a science, and as it has been observed in all history, is a heterogeneous mixture of witchcraft, superstition, charlatanism, empiricism, fanaticism and deception.

In direct ratio as the knowledge of individual and collective humanity increases does medicine become more and more a science.

Humanity implies a physical, mental and moral being; "a material body, an immaterial mind and an immortal soul." These three elements, although distinct, are strangely blended to make man. So intimate is their connection, so intricate the process by which they are interwoven, that no proper conception can be had of mankind, by the study of one of these elements to the exclusion of the others. We must comprehend the fact that all impressions and influences, made either from within or without the man, involve his *threefold* character.

Errors are not uncommon in this regard, in the application of the science, or, if you please, the art, or practice of medicine. To regard man only from a physical standpoint leads to errors, both in regard to the causes and the cure of his diseases. To regard him as mind only, and conclude that all his ailments are mental or imaginary, leads to the most erratic conclusions, and to the inexcusable and criminal neglect of material agencies, whereby the loss of life may result, instances of which are not uncommon, even *in this enlightened* age and under our own observation.

To dwell only on that which is immortal; to regard the soul only; to look on all diseases as the result of immorality and sin, leads to the most fanatical practices, fraught with great evils to both body and mind, and may result in the overthrow of the soul itself.

In the application, then, of the science of medicine, due regard must be paid the body as a great complex mechanism, a co-ordination of the physical forces of which is so essential to the welfare of the whole. We must consider that the mind wields a large influence over the body, both in health and disease, and our therapeutics must include agencies whose effects are mental in their application, as well as those which are physical.

To administer to a mind diseased; to bind up the wounds which sorrow has made; to sympathize with distress; to inspire hope and strengthen confidence are among the most difficult problems of medical men, a proper solution of which may bring healing and health to the body. Not the least of the three factors is the soul of man. That which is neither physical or mental, but a distinct entity, breathed into man by the Infinite, and creating him a moral being. The causation of some of the most unmanageable diseases, both of the body and mind, is traceable to immorality, the cure of which is improbable, if not impossible, unless the moral perversion can be overcome. We conclude, then, that only by the diligent study of individual man, physical, mental and moral—can we have the knowledge or science of humanity that is so essential to the application of the science or knowledge of medicine. All rational therapeutics have their basis on these principles; all else is empiricism.

What think you, then, of a physician (so-called) who presumes to administer remedies to those who fall by the wayside in the struggle of life, who knows but little of the body, less of the mind, and who cares nothing for the soul? What would you think of a man who, knowing absolutely nothing of a locomotive, should mount the cab of an engine, to which is attached a train of cars laden with human freight, and with a reckless daring, born of ignorance, should open wide the throttle, and perchance hurl the unsuspecting passengers to death? Before a man may run an engine he must study long days and weeks and months under a master. He begins by wiping off the engine, studies each piece of the ponderous machine, becomes familiar with every wheel, piston, cog and valve. He must understand the gauges, the brakes, the signals, the power of the mighty iron horse, indeed, everything connected with the mechanism of locomotion, and even then he is not competent until he shall have taken his stand by the engineer and gone over the road again and again, observed every switch, bridge and landmark, and even then he assumes the position with fear and trembling at the mighty responsibility. This law of qualification applies to every avocation, and is prerequisite to every business or undertaking.

---

* President's address, delivered before the Tennessee State Medical Association at its annual meeting in Chattanooga.

So should it be with the physician, or with anyone who assays to administer remedies to the diseases of tripartite man. He begins, perchance, sweeping the office and arranging the books and instruments of his preceptor. He spends weary months and years acquiring a knowledge of the structure of the body. With scalpel and forceps, in the weird light of the dead room, he dissects the brain, the heart, the lungs; indeed, all the organs of the body; observes their size, their structure, their position and relationship to other organs, their blood and nerve supply, then traces the source and distribution of every artery, vein and nerve, studies the bony framework of the body, its muscles, joints and ligaments, and then, with microscope in hand, looks down into the ultimate cells, scrutinizes the constituents of the blood—the very source of life—compares healthy with diseased structure, and learns to distinguish the normal from the abnormal.

But his work is just begun. Turning to his physiology, he must know the offices performed by the various organs, the character of the secretions and excretions, the processes of waste and repair, the functions of digestion and assimilation, of respiration and circulation. Then, through the biologic laboratory, study the germs of disease and behold their work of propagation, and the manner of their subtle invasion and destruction of the tissues and organs of the body in their hidden fastnesses. He must also know materia medicine, the character and properties of drugs, their action on the human economy, their incompatibilities, their poisonous effects and antidotes. If a surgeon, he must, in addition to all this, understand the technic, the instruments required, and the elaborate principles of asepsis and antisepsis involved in an operation. Then, again, the student must acquaint himself with the more delicate subjects of conception, the growth and development of the fetus in the uterus, the process of parturition, the advent of the newborn child, its needs, together with those of the mother, at that critical and trying period.

He must take his stand at the bedside of the sick and injured, and study disease in its different stages and [illegible]ifestations; the indications for treatment, the dan[illegible], immediate and remote, the diseases peculiar to in[illegible]cy, middle life and old age, the natural changes that occur in the body during the periods of growth and decline. He [illegible]ider also the mental and moral traits of the [illegible]vironments, his habits, his hereditary predisp[illegible] tendencies to particular diseases. He must [illegible] in the sick room a professional man[illegible] confidence in his own ability and re[illegible] inspires confidence in the patient [illegible] that the chief mission of the phy[illegible] if possible, he will often be [illegible] conditions that defy his best[illegible] hopelessly incurable. But even after all his resources have been exhausted, the true physician does not forsake his patient. But when in the shadow of an overwhelming fate he recognizes the approach of the relentless messenger as he comes to summons the soul to its final account, he should soothe the pain and anguish of dissolution, and point the weary sufferer through the darksome portals that mark the end of this mortal span, but which open the entrance to the land Elysian.

After all this preparation, and much more not laid down in books or "nominated in the bond," a man with a conscience enters on the duties of doctor of medicine with a sense of obligation and responsibility well nigh paralyzing.

Contrast, if you please, this student, well bred in the sciences of humanity and medicine, with the conscienceless quack, the presumptuous charlatan or the greedy and avaricious manufacturer of secret and patent medicines, who are in the business of tampering with human lives, not for the study of the science of medicine, as applied to human needs, but like the would-be statesman in defining his position, favored a "tariff for revenue only."

But you say: "Why do people allow themselves to be imposed on by the pretender in medicine, and why do they buy and use drugs of which they know nothing and for the administration of which no one is responsible?" There are several reasons. As far back as we have any account of the human race there has existed in the mind a disposition to fathom the mysterious and to experiment with the unknown; it was this that led Mother Eve "to partake the fruit of that forbidden tree, whose mortal taste brought death into this world, and all our woe." Then, again, for thousands of years of the world's history medicine as a science had no existence, the treatment of disease being a mixture of witchcraft, incantation, exorcism, deception and cruel imprisonment or banishment. From that dark age of mythology and superstition the human mind has emerged very slowly. Errors easily find lodgment in the mind which require great effort and hundreds of years of time to eradicate, people preferring to hug the delusions of the fathers rather than accept a scientific truth.

There is also a kind of credulity in the human mind easily played on by the fair promises and assurances, the flaming advertisements and attractive chromos, which are a necessary adjunct to the success of the quack and patent-medicine man. Again, there is magic in printer's ink. People are prone to accept as fact what they see in print.

Contributory to this patent-medicine frenzy are the certificates of public men, even ministers of the gospel indorsing this stupendous folly. The apology we would offer for these is that, however wise and good they may be on other lines, they know nothing in regard to medical science, and in any court of the country their testimony would be ruled out on the score of incompetency. There are also church papers, and even some medical journals that allow (for a consideration) space in their publication to advertise these frauds. Ministers of the gospel and church papers need be more cautious lest they become accessory to the formation of most pernicious drug habits. People attach much importance to the opinions of ministers and the indorsements of the religious press.

There is just one other class of which we would speak, but with diffidence, for he is our brother, and for him we entertain a good degree of regard and would not, wantonly, wound his sensibilities, but we have heard it said that some real physicians do now and then permit the use of, and have actually been known to prescribe a preparation, a medicine (so-called) a something, the ingredients of which were entirely unknown to them, and that there have appeared in certain quarters certificates from doctors indorsing such nostrums. Is it possible?

I know that my brother is sorely tempted, for the ubiquitous agent besieges his office day after day with an exhibition of his wares, extravagantly loads his table with samples and is persistent in his praises of the virtues of the articles contained in the cartooned packages, ready made for all the ills to which human flesh is subject. But, brother, as in moral and spiritual matters, there is a way of escape from temptation by resisting the powers of darkness and ignorance. So in the practice of your art, you can escape the clutches of the commercial medicine man by confidence in and fidelity to our noble science. Thereby you will contribute to the best interests of your clientele, maintain your self-esteem and advance the honor and dignity of your profession.

The medical profession condemns these patent nostrums, and the methods of quacks, advertising specialists and impostors, not because of their interference with the business or financial interest of the physician, but for the same reason that we urge medical legislation for the protection of the health and lives of the people. Men of medical science know the pernicious effects of the narcotics and stimulants contained in many of these mercantile preparations and nostrums. The cunning manufacturer well understands how to increase the sale of his wares by loading them with drugs that entail habits and thereby his preparation creates its own demand. He is in the business for money.

On the other hand, every law on the statute books relative to the prevention of disease, the arrest of epidemics, quarantine regulations, the organization of state boards of health, the United States Marine-Hospital Service, the institution of the various public health associations, prison reform, the erection and equipment of hospitals for the insane, blind and disabled, every sanitary regulation—state, county and municipal—have had their origin in the medical profession and received the hearty support of medical men everywhere, and that without the hope of fee or reward. Yet humanity, bleeding from every pore, suffering from all sorts of imposition, from quacks, impostors, nostrums venders, faith cures, *et id omne genus*, repeats again and again the cry that rang out in the oriental court of a Roman governor on a certain momentous occasion: "Give us Barabbas! Give us Barabbas!" The historian of those times incidentally mentions the fact that this Barrabbus was a robber.

Again, the tendency to disregard the injunctions of medical advice and to violate the most common principles of the laws of health, is a marked characteristic of humanity. Physicians and health officers have often been seriously handicapped and blamed for inefficiency, when in reality, alleged failures were occasioned by indifference to their suggestions. In the writer's own county, a few years ago, a case of smallpox was found in the practice of a competent physician, who immediately reported the case to the county board of health, and urged the necessity of isolation and quarantine of the patient, together with all who had been exposed to the contagion, and the vaccination of the community in which the case occurred. After considerable trouble and delay, this was accomplished, but only a few days afterward the county judge, in the face of the protest of the health officers, dismissed the guards and turned the infected negroes loose on the town and country. The result of this blunder was to precipitate an epidemic of smallpox that cost the county some forty thousand dollars, to say nothing of the loss of life and the suffering from a loathsome disease. Another melancholy incident of the kind occurred in the neighborhood of this city (Chattanooga) during the Spanish-American War, when the flower of American manhood encamped at Chickamauga were stricken down with a preventable disease and died by the score, not on account of the inefficiency of the medical staff, but because of the total and offensive disregard of their advice, by an arbitrary commanding officer.

Not only is there this indifference in regard to medical science as it relates to humanity, but there exists a spirit, especially among some aspirants for political office, a kind of pandering to the unlearned—a species of demagogery, of you please—in order to secure or maintain official position. This class of men, as a rule, are opposed to all progress in matters of science; they draw the line at what they are pleased to call innovations, and claim to have great love for the dear people. You will find them opposed to medical-practice laws, opposed to vaccination, opposed to sanitary regulations, not in sympathy with health boards or quarantine regulations, opposed to all sorts of prohibitory measures and reform movements. This character has been, in the past, quite an obstacle to progress, especially to medical progress, but his days are numbered. The people are becoming better informed on these lines, and are beginning to suspect that it is not so much his love for them, but for his own advancement, that he has been led to sacrifice (?) himself on the public altar.

Greater advances in the interest of humanity will be made by medical science in the near future, in consequence of the better organization of the profession. The county, district, state and American medical associations being now placed on a new basis, can exert a greater influence in regard to legislation, and on all matters pertaining to the prevention of disease, the preservation of health and the prolongation of human life.

Some of the advances contemplated are of such general interest that they can only be secured through national legislation, such as the Pure Food Bill, which has recently passed the House of Representatives, and which we trust will become a law. Coupled with this should be established a department for the inspection and analysis of medicinal plants and pharmaceutical products, together with all secret nostrums and patent and proprietary preparations. Manufacturers of these latter compounds should be compelled, under the law, to label in plain language their preparations, giving the name and amount of every ingredient contained in them. Heavy penalties should be fixed for the adulteration of drugs or for misrepresentations in regard to the ingredients contained in a given compound. There should also be established some national system for the destruction of mosquitoes, now known to be the instruments in the propagation of malaria and yellow fever, and of rats, the carriers of the infection of bubonic plague.

Another subject of national importance is the study

adore, when sickness comes, not before. When we get well, both are alike requited; God is forgotten, and the doctor slighted." But a period in the near future shall mark the triumph of science over darkness and superstition, and the physician no longer be summoned only in emergencies to apply his art to the cure of maladies produced by a disregard of the laws of health, but he shall be an officer of state, clothed with honor and authority and salaried by the government. His mission shall be as an apostle of the goddess Hygeia to teach the people the science of health—the art of keeping well. Under his genial administration crime and disease shall be the exception, peace and health rule. Healthy parents shall behold with pride the rosy cheeks of their children, which, like olive plants, shall grow up and become fruitful. National prosperity and happiness shall be the result of a symmetrical manhood and womanhood endowed with physical strength and beauty, mental excellence and moral rectitude. Mankind shall not be hurriedly summoned from the stage of the world's drama in the innocence of childhood, the bloom of youth or the busy activities of middle life, but in a green old age at the nightfall of life, willingly yield to the influences of a gentle and peaceful euthanasia.

ACUTE ASCENDING PARALYSIS AND LANDRY'S PARALYSIS.

L. HARRISON METTLER, A.M., M.D.

Professor of Mental and Nervous Diseases in the Chicago Clinical School; Associate Professor of Neurology in the Medical Department of the University of Illinois; Neurologist to the Norwegian Lutheran Deaconess' Home and Hospital.

CHICAGO.

At the present time there is much confusion of thought, and not a little conflict of statement, as to exactly what is meant by Landry's paralysis and as to the true nature of the disease. Landry's paralysis and acute ascending paralysis are by no means always the same, and yet the terms are used synonymously. There must be a middle ground whereon they overlap to warrant this synonymous use of the two names. A clear conception of the nature of this middle ground, from both the clinical and pathologic points of view, will not only go far toward explaining the dissimilar cases lying outside of it and on either hand, but it will help to accomplish what is of far more practical importance, for it will afford greater unity, definiteness and coherency in the treatment of all cases. The purpose of this paper is to clear up a little, if possible, the confusion still surrounding the present conception of acute ascending paralysis. The following propositions, resting on clinical and laboratory observations, will be discussed, and in the end certain definite, practical conclusions will be attempted:

(*a*) Landry himself described not a new disease—not even *a* disease—but rather a symptom-complex or clinical picture, which included much less than what is now included under the term acute ascending paralysis.

(*b*) Both Landry's disease and acute ascending paralysis are recognized to-day as mere phases of a particular form of specific intoxication of the nervous system.

(*c*) The proof that this intoxication is of bacterial origin, the particular micro-organism, if, indeed, there is a particular one being still unknown, is about established.

(*d*) This bacterial intoxication produces functional disturbances, and later on diffuse inflammatory and degenerative changes in various parts of the central and peripheral nervous apparatus, thus accounting for the variability of the clinical phenomena.

(*e*) Time, virulence of the poison and resistive power of the patient are the principal factors that determine the nature of the pathologic findings and the clinical form of the trouble. Under some circumstances the postmortem findings may be *nil*, while under other circumstances they may be highly suggestive of a diffuse myelitis, an acute anterior poliomyelitis or a peripheral multiple neuritis. It is an error, therefore, to identify Landry's paralysis, or even acute ascending paralysis, always with one or the other of these diseases.

(*f*) The recognition of the class of cases under discussion, as a form of diffuse bacterial intoxication, not only explains most satisfactorily their striking clinical discrepancies, but suggests a far more rational guide for their management than has any explanation hitherto offered.

If we are to limit the definition of Landry's paralysis to what Landry himself described in 1859, we must narrow it to an acute ascending paralysis, flaccid in character, rapid in progress, without disturbance of the reflexes, without muscular atrophy or electrical changes, without sensory phenomena and without implication of the vesical and rectal functions; usually fatal in a few days with respiratory involvement; and devoid of all discoverable postmortem pathologic changes. Such a definition, however, is not comprehensive enough to include the modern conception of acute ascending paralysis. Cases are on record wherein the paralysis was not of the regularly ascending type, but had descended and even skipped about from arm to leg and from side to side. In these cases, moreover, sensory symptoms appeared early; typical muscular atrophy was present; and there were well-recognized alterations in the electrical responses.

Not a few of the cases recovered. Among those that were fatal, postmortem examinations, made in accordance with the more delicate modern methods, revealed distinct inflammatory hemorrhagic and degenerative lesions. Thus, from both the clinical and pathologic points of view, the description of acute ascending paralysis has to be drawn on much more extensive lines than those adopted by Landry and his immediate followers. As we proceed with our discussion, it will be seen that Landry described merely a symptom-complex or group of cases that form a part of a much more distinct and comprehensive group.

Among the first to break entirely away from Landry's narrow conception of the disease were Taylor and Clark, who, in 1900, wrote: "On the basis of an acute, clinical and necessarily highly superficial pathologic observation made many years ago by Landry, subsequent observers, led largely by a name, have been attempting to force into the narrow clinical conception outlined by Landry, various symptoms, none of them fundamental and supported by no constant pathologic findings and still less by a definite etiology. The so-called disease has, with each new investigation, lost something of its coherence. We have persistently clung to a name, and demanded that symptoms which it represented should conform to our preconceived idea." These words voice the opinion of Dejérine, Schwab, Schmaus, Diller and others. To separate such groups of cases as Landry described and give them the name of a distinct disease, is an arbitrary, useless and confusing procedure. It belongs to that sort of ultra-refining classification which makes a special disease, ataxic paraplegia, for instance, of a mere combination of lateral and posterior sclerotic degeneration, or enumerates a half dozen or more types of chorea out of a mere symptomatic form of muscular movement.

It is much more rational and practical to regard all of the groups of acute ascending paralysis as merely particular manifestations of a diffuse, specific intoxication, which intoxication is rendered more or less variable by such factors as the duration of exposure, the virulence of the poison and the particular susceptibility of the patient; and which, therefore, reveals itself in one or other of the clinical types of the disease described above. The one point in which these various types of acute ascending paralysis all seem to agree, and which justifies, probably, the recognition of it as a more or less distinct disease, is its apparent limitation to the lower or peripheral neurons. If perchance some day a specific microorganism should be discovered as the cause and the *only* cause of Landry's paralysis, the ground for considering the latter as a distinct and uniform disease would be quite unassailable. At present no such ground exists.

Let us now consider a little more in detail the modern clinical picture of acute ascending paralysis, so as to discover, if possible, its likeness and unlikeness to other well-known forms of disease, such as multiple neuritis, acute anterior poliomyelitis, acute meningomyelitis or acute ascending myelitis. With Landry we agree that there is a group of cases in which there is a rapidly ascending paralysis, motor in type, flaccid in character, beginning usually in the lower extremities and then passing to the upper limbs, and finally causing death by involvement of the bulbar functions, especially respiration. In its upward, rapid course this paralysis creeps, as it were, from the feet to the neck. Even the muscles of the trunk and throat do not escape. Deglutition and articulation are affected. Cheyne-Stokes breathing is frequently present, and asphyxia with diaphragmatic paralysis usually closes the scene. So swift and profound is the disease that it is almost appalling at times. I have seen it terminate in death a few hours after its first manifestation. Generally it lingers a few days, death occurring, as a rule, within a week. In the exceptionally rapid cases the reflexes may be found as yet undisturbed. In the larger number, however, there is more or less loss of the deep and superficial reflexes. Only in a few prolonged cases do muscular atrophy and abnormal electrical reactions appear. The bladder and rectal functions remain normal. Sensation is rarely, if ever, disturbed. The mind continues clear. Often in the beginning there is a slight elevation of temperature, but this quickly subsides and remains at normal. This peculiar elevation of temperature, with hyperidrosis, mild delirium and other signs of a general septic infection, appears rather frequently in the more recent reports. Postmortem examinations reveal no lesions inside or outside of the nervous system, no changes of any sort, except the rather frequent enlargement of the spleen. Such, in brief, is the modern typical Landry's paralysis. It is the definition of Leyden, approved by Thomas, that is accepted nowadays.

From this type, however, we recognize many divergent forms. For instance, Mills and Spiller, after adopting the definition of Leyden, admit a descending type of the disease in which paresthesia, without severe or persistent pain, is a prominent symptom. Clinically, the picture of Landry's paralysis undergoes some most noteworthy and suggestive changes, especially in those cases that have escaped a fatal issue, and that gradually subside after a comparatively long period of duration. Moreover, these prolonged cases, when they do die, reveal at the autopsy some very striking and suggestive pathologic changes.

The modern clinical divergent types of the disease are to be found anywhere within the extremes of a multiple neuritis on the one hand, and an acute anterior poliomyelitis on the other. So completely, indeed, have we faced about, that Diller, in his exhaustive study of Landry's paralysis, now assigns the first position, both in regard to time and importance, to the sensory symptoms.

Including these divergent forms of the disease, then, *Landry's paralysis, in the most modern sense,* must conform to the following conception:

It does not always regularly ascend. It skips about. Occasionally it appears first in one leg and then in the opposite arm, to continue in the other leg and finally in the other arm. One leg and both arms, or both legs and one arm, may represent its distribution. Fagge states that the great naturalist, Cuvier, succumbed in a few days to an acute descending paralysis which bore all the signs of Landry's disease; while Oppenheim reports a case in which only bulbar symptoms were present. Rowden's case was of the descending type, and in Howard's case bulbar symptoms showed themselves first, and then in order involvement of the following muscles: hip, thigh, shoulders, arms, legs, hands, feet, lips and diaphragm. I recently saw a case in which bulbar symptoms appeared early, but diminished as the paralysis attacked other muscles of the body. The cranial nerves are sometimes involved, as shown by the facial paralysis, diplopia and paralysis of accommodation, all of which have been reported as a part of the picture of Landry's disease.

A certain degree of muscular atrophy has been observed in some cases, so much so that they quite resembled an extensive form of acute anterior poliomyelitis. The electrical reactions have also been seen to undergo the well-known changes characteristic of degeneration in the lower motor neurons. In Burghart's case, quoted by Knapp and Thomas, there were typical electrical reactions of degeneration. In a case of Oppenheim's, the nerves and muscles reacted to weak electrical stimulation, but an increase in the current strength did not increase the intensity of the contractions. Even the strongest current failed to secure a pronounced contraction. Curiously enough, on several occasions, a strong current produced no contraction at all or a weaker one than that evoked by a weaker current. Oppenheim says that a piece of the muscle showing these peculiar electrical phenomena revealed on examination a waxy-like degeneration. The symptoms disappeared with the recovery of the patient.

So far as I know, very few cases have been observed or reported in which the sphincters were involved. Oppenheim, however, is authority for the statement that complete sphincter paralysis does occur. In Goebel's case the vesical sphincter was weak, and late in the disease there was diminished sensation. Sphincter troubles were noted in Knapp and Thomas' three cases.

More remarkable than all this is the frequent association in the modern cases of Landry's paralysis of pronounced sensory with the motor phenomena. The sensory disturbances have been of every variety, but chiefly in the pain, temperature and touch spheres. From hyperesthesia to anesthesia, hyperalgesia to analgesia, all along the line of the various paresthesiæ, have the sensory manifestations been observed. These cases have been reported by such competent observers as Robinson, Taylor and Clark, Mills and Spiller, Worcester, Marie and Marinesco, Hirtz and Lesné, Oettinger and Marinesco, Diller and others. Early sensory symptoms, in some cases before the onset of the paralysis even, have been seen in cases reported by Schwab, Wappenschmidt, Griffith, Kapper,Maxwell, Stockton, Diller and others. In the words of Diller: "In the symptomatology of Landry's paralysis, sensory symptoms are almost constantly present and generally precede the motor paralysis by several hours or a day, occasionally by much longer periods." Pains are found in many of the cases. They are of the nature of local tenderness and neuralgic pains, and in this respect are highly suggestive of peripheral neuritis. They are elicited by pressure on the muscles and nerves and by passive movement. Though frequently complained of, these pains after all are, as a rule, absent even in modern Landry's paralysis. A complete loss of sensation is so rare that anesthesia falls short of being an important symptom. Fugitive and variable paresthesiæ are occasionally noted. After all, it is true, as Oppenheim says, that, as a rule, gross sensory disturbances are absent in Landry's disease. When they are present it is at times practically impossible to differentiate the case from one of polyneuritis. And yet it is a mistake, as I will endeavor to show later on, to identify Landry's paralysis with peripheral multiple neuritis, as Ross and his followers have done, and to declare that they are one and the same disease.

In summing up, then, as Buzzard so well does, the clinical conception of modern Landry's paralysis, we may classify the cases under three heads. The first class includes those that are marked by motor palsy, absent reflexes, absent electrical changes, slight paresthesiæ and absence of muscular atrophy. These are the cases in which no postmortem findings can be demonstrated by the use of osmic acid and the Nissl method. In the second group of cases there are more advanced motor and sensory symptoms, some slight electrical reactions and trophic phenomena. In these cases there is in all probability a degeneration of the motor and sensory neurons, with beginning chromatolytic changes in certain ganglion cells. In the third class of cases are to be placed those that exhibit still more pronounced motor and sensory symptoms, sphincter disturbances, typical muscular atrophy and electrical changes. These cases are probably characterized by advanced changes in both the neuron bodies and their processes.

A careful study of the pathology and pathogenesis of acute ascending paralysis, so far as we have data at the present day for such a study, leads almost conclusively to the opinion that the trouble is merely a manifestation of a profound form of toxemia, in which the toxin expends its force chiefly on the lower neurons. In the earlier descriptions of Landry's paralysis. there were no postmortem findings. Westphal confirmed this, and both he and Landry, therefore, adopted the toxemic theory of the disease. Others who have failed likewise to find any postmortem changes in the nervous system include such careful investigators as Kahler, Pick, Greppin, Ranvier, Vulpain, Bernhardt, Dejérine and Goetz, and Hun. It may be that in some of these cases the early and faulty technic should be blamed for the inability of the examiners to find any pathologic alterations, while in others the lack of thoroughness in the examination must bear the responsibility. For instance, in one of Westphal's cases, only the cervical part of the cord was examined. As later observations seem to show that both the cervical and lumbar parts of the cord are equally important centers of attack, it is possible that changes might have been discovered in the lumbar region. Again, it is not improbable that in long-running cases, such as another of Westphal's, the lesions may have disappeared and the exudates have been absorbed before death finally took place. All of this may reduce the number of cases with negative findings. Nevertheless, it must be admitted that cases do come to the autopsy that do not reveal the slightest sort of pathologic change. The more recent reports of Ormerod and Prince and of Giraudeau and Levi confirm this. The number of such cases, under the more accurate and painstaking methods of modern times and the use of the osmic and Nissl staining technic, has been gradually decreasing, until now they constitute quite a small minority. It may well be imagined that in these minority cases the virulence of the poison or the special susceptibility of the patient brought about the fatal termination before any histopathologic changes were possible.

Landry, Westphal and the other early investigators were supported in their belief that acute ascending paralysis was due to a profound toxemia by the frequency with which they found on postmortem examination enlargement of the spleen, old hemorrhagic remains in the lungs and bowels, inflammation of the lymph glands and occasionally albuminuria. Gowers long ago made the shrewd suggestion that the not infrequent paralysis of accommodation seen in cases of Landry's disease confirms its toxic origin, because the isolated acute paralysis of a functional center, not anatomically separate from others, is known to be caused only by a toxic influence. The more recent work of special observers has almost absolutely established the toxic origin of the disease. For instance, Baumgarten found that in all probability anthrax was present in a case seen by him. The bacilli were discovered in the blood and tissues. In a case reported by Curschmann, though there were no clinical manifestations of typhoid fever, the characteristic intestinal lesions were present, and pure cultures were obtained from the typhoid bacilli discovered in the spinal cord. Bacilli were seen by Centanni in the endoneural lymph spaces of a case in which there was an interstitial neuritis. According to Eisenlohr, there were found in some cases various kinds of bacilli in the central nervous system, especially staphylococci. This author is inclined to attribute Landry's disease to a mixed infection. He does not believe that the micro-organisms are necessarily constant. Indeed, they may be entirely absent or the spinal cord alone may be affected by them. Among the other micro-organisms that have been found in different cases may be mentioned the *Streptococcus longus* by Remmlinger, a diplococcus by Marinesco, the anthrax bacillus, or one much like it, by Marinesco and Marie, and the so-called Fraenkel-Weichselbaum bacterium by Seitz. Bacteria have also been discovered by Burghardt, Friedlander and Giese, Mouravieff and Montourine. Oettinger and Marinesco and others. Even more direct evidence than all this of the bacterial origin of the disease has been furnished by the cases of Courmont and Bonne, Piccinino, Roger and Josué and others. Very recently Buzzard detailed a typical case of Gowers, in which he discovered a diplococcus from which pure cultures were made, and from the injection of which into rabbits he obtained in these animals a symptom-complex identical with Landry's paralysis. As this micro-organism was found in the dura mater, Buzzard suggests that it be called the *Diplococcus thecalis.* He says that it does not conform with any previously discovered organism. In addition to Buzzard, Thoinot and Maselli have produced in animals the typical clinical picture of Landry's paralysis by the injection of micro-organisms into the blood and spinal cord (Oppenheim).

Whether the relationship is etiologic or not, it is a most suggestive fact that Landry's paralysis has been seen to develop after malaria, diphtheria, typhoid, variola, anthrax, influenza, pneumonia, pertussis, septicemia, gonorrhea and the puerperium. Once it occurred after the Pasteur treatment for rabies, and sometimes it has been attributed to syphilis and alcohol.

In a considerable number of cases. diagnosed as Landry's paralysis, changes were found in the peripheral nerves indicative of an interstitial and parenchymatous neuritis. Since Ross' exhaustive and valuable study of multiple neuritis, wherein he classifies Landry's disease as a form of polyneuritis, many have adopted the view that acute ascending paralysis of the Landry type is but a phase or manifestation of peripheral multiple neuritis. Ross based his conclusions, which in the main agree with those of Nauwerck and Barth, on a tabulated series of 93 cases. Among those who follow the teachings of Ross may be mentioned Dejérine and Goetz, Klumpke, Centanni, Kirilzew and Mamurowsky, Dydynski, Krewer, Walton, Putnam and others.

In another group of cases evidences of the disease were found only in the spinal nerve roots; and according to Buzzard, such changes are more frequent in the anterior than in the posterior roots. Oppenheim records that in one case merely a degeneration of the anterior roots was discovered. In Hun's case the results of the autopsy were negative, except for a slight cerebral and spinal meningitis and a degenerative neuritis of some of the fibers of the anterior roots of the cauda equina. Cultures were made, but no bacteria were found.

A third class of cases were characterized especially by spinal-cord involvement. Such cases have been reported by Eisenlohr, Schultze, Ketli, Hlava, Immerman and others. Disseminated foci of inflammation, exudates and capillary hemorrhages in the medulla and cord, swelling of the axis cylinders in the white matter of the anterolateral tracts, poliomyelitic remains, etc., have been the usual findings. Iwanow's two cases were highly instructive. The cervical and lumbar enlargements showed a concentration of the disease process, and at these points it was more or less limited to the central canal with extension into the anterior horns. It consisted of an exudation of lymphoid bodies, fibrinous exudates around the vessels and nerve fibers, the result of an inflammation, disintegration of the axons, swelling and indistinctness of the neuron bodies. An edema surrounded the vessels. The nerve roots and meninges were normal; bacteria were absent. The cases of Eisenlohr and Krewer showed both neuritic and myelitic processes. In Kirilzew and Mamurowsky's case there was marked acute primary parenchymatous neuritis of the nerves of the feet, legs and forearms, and to a lesser degree of the roots of the cervical and lumbar enlargements. The cord itself was hyperemic. with cloudiness of the gray substance, slight atrophy of the anterior ganglion cells and an accumulation of cortical cells in and about the central canal. Clark has described a fluid exudation about the central canal on a level with the lumbar nerves. Baumgarten, Eisenlohr and others have noted similar findings. In Kleb's case there was pericardial tuberculosis and widely distributed hyaline thrombi in the branches of the central artery of the cord. They were most numerous in the lumbar region. Secondary phenomena were minute hemorrhages and exudations, especially in the ganglion cells. The peripheral nerves were intact. The thrombi were probably of toxic origin. From the symptoms of a case which ultimately recovered, Sanger Brown believed that the chief disturbance was in the lumbar and cervical enlargements. The reflexes were exaggerated and there was an ataxic paraplegia. Touch and temperature sense were diminished somewhat. Carter's case, which also recovered, exhibited a similar picture. Both of these cases bore a singular resemblance to syringomyelia, with implication of the tissues immediately surrounding the central canal. In nearly all of these myelitic cases, a predilection is shown by the disease process for the immediate neighborhood of the central canal in the cervical and lumbar enlargements.

Finally, a fourth class of cases has been reported, in which all parts of the lower motor neuron, peripheral nerve, spinal root and ganglion cell were involved in a scattered and diffuse pathologic process. In a rapidly fatal case. Spiller found changes in the peripheral nerves and similar alterations in the cell bodies of the anterior cornua. Thomas has reported two cases with similar findings. In fact, Spiller, Mills and Osler all define Landry's disease as an acute poisoning of the lower motor neuron.

With all this pathologic evidence in hand, one can not escape the conclusion of Buzzard that Landry's paralysis, in the modern sense, is the result of "a local infection, a general pyemia, or lastly and most frequently of an acute intoxication"; and that, in the words of Taylor and Clark, it exhibits "no essential constancy in the clinical symptoms nor in the pathologic findings and the etiology is wholly vague."

In view of this widely varied picture of the clinical and pathologic presentations of so-called Landry's paralysis, the exact meaning of the name and the advisability of its retention both press for answer. It is the steady aim of science to simplify and generalize, as far as known data will warrant, all knowledge. At one time the term Landry's paralysis seems to have stood for a certain definite clinical entity; now it is applied to conditions as unlike those originally classified under it as day is unlike night. In behalf of scientific accuracy, one of the following reforms is imperatively demanded; the term itself should be irrevocably dropped, or a new and greatly expanded conception of its meaning should be adopted, or the symptom-complex which it represents should frankly be recognized and so treated in the text-books as one of the many possible phases of a particular, well-known disease process. There are advocates for all three ways out of the difficulty. Personally, I incline to the third or last way.

Diller suggests that the name Landry's paralysis, defective as it is, to define our modern conception of the trouble, is nevertheless convenient for practical purposes, much as the term apoplexy is which, in itself, means nothing, but yet covers a certain set of clinical phenomena that may be caused by a number of more or less obscure pathologic changes. If the term

Landry's paralysis were only as indefinite as the term apoplexy, Diller's suggestion might be commended, but unfortunately the term Landry's paralysis does stand for a distinct, well-marked clinical picture, and therefore can not justly be made to cover all the varied groups of cases that it is made to cover to-day. Furthermore, it is a question whether the art and science of medicine are not greatly hampered by the retention of names for the mere sake of practical convenience, when those names are so positively misleading as the name Landry's paralysis is when applied to some of the grossly divergent forms of the trouble reported nowadays.

The suggestion of Diller virtually amounts to an absolute denial of such a disease as Landry's paralysis, in which denial most of us will probably acquiesce. The distinct clinical manifestation, however, described by Landry in 1859 and since known by his name, can not be denied. It is a clearly defined entity, whose relationship to some more extensive disease process we may later on discover, but whose name we can not justly or wisely apply to manifestations which Landry, perhaps, never dreamed of when describing his particular symptom-complex.

Those who still cling to the name, recognizing the definiteness of the clinical picture which it was originally made to cover and who are loath to give it up for any reason whatsoever, adopt a curious mode of scientific logic. They eliminate from consideration all reported cases that do not absolutely conform to Landry's original description. Some very recent writers, notably Goebel, have adopted this procedure, while Bailey and Ewing, in 1896, rejected from their 75 collected cases, 31; namely, the cases of Bernhardt, Pitres and Vaillard, Hayem, Pribytkow and Brochain, because there were marked sensory phenomena present; the cases of Vierordt, Strümpell, Eichhorst, Diller and Meyer, because their course was chronic or prolonged; and the case of Roth, because it was not ascending in type. As a collection of cases strictly illustrating what Landry meant by his paralysis, the retained list of Bailey and Ewing is a happy hit; but such a method of classification, it seems to me, is of no value whatever, unless it can be clearly shown that the rejected cases were absolutely unrelated, clinically as well as pathologically, to those of the retained list. In other words, any man may describe any sort of a symptom-complex, and the chances are ten to one that a tolerably good list of cases that will correspond may be gathered together. The real question is not as to the number of cases that correspond merely with Landry's definition, but as to the reliability of Landry's description as a definition of a unique and distinct disease, and of the relationship of it, if any, to more extensive disease processes or of the divergent, rejected cases to it.

Viewing the question from all sides, then, the following conclusion may be accepted as fairly representative of the modern conception of Landry's paralysis and its relationships. There is a form of nervous intoxication, whether specific or not unknown, in which the lower motor neuron is selected to bear the brunt of the trouble. The character and distribution of the lesion in this lower motor neuron and its associated structures, together with the consequent clinical picture produced by that lesion, are dependent on many factors, chief of which are the virulence of the poison, the duration of the disease and the individual susceptibility of the patient. One phase of this intoxication is covered by the definition of Landry; other phases are the symptom-complexes that closely resemble multiple neuritis, acute anterior poliomyelitis and acute ascending meningomyelitis.

This being so, it is worth while considering for a moment the differential diagnosis between this intoxication and the well-recognized forms of disease which it so often closely resembles.

If we believe, with Ross, Raymond and others, that a multiple neuritis is the pathologic basis of all these cases of acute ascending paralysis, we must either enlarge our symptomatology of multiple neuritis or contract that of the class of cases now under consideration. Without doubt there are cases so near to the borderline between the two classes of disease that a differential diagnosis is absolutely impossible. Such cases are not numerous enough, however, to afford ground for the belief that acute ascending paralysis is always a multiple neuritis, or to render a differential diagnosis a matter of useless effort. Multiple neuritis is something quite distinct, both pathologically and clinically, from the forms of neurotic intoxication included under the generic term acute ascending paralysis. In multiple neuritis the regular appearance early in the disease of sensory symptoms, usually before the motor manifestations, the paraplegic and more or less symmetrical distribution of the paralysis, the ataxia and other special motor phenomena, the electrical changes, the loss of the deep reflexes, the rapid muscular atrophy, the delirium and other mental accompaniments, and finally the slower course of the disease process and the more favorable prognosis are sufficient to discriminate multiple neuritis clinically. Pathologically the less generally diffuse or focal character of the lesions, the comparative absence of lesions outside of the nervous system, and the comparatively less involvement of the cerebrospinal axis proper with these scattered diffuse lesions are characteristics of polyneuritis. In this disease, moreover, there is decidedly more fever, and the bulbar symptoms are not so obtrusive. The paralysis is not so regularly of the ascending type. The age of the patient and the presence of an alcoholic history are also matters for careful consideration.

From acute anterior poliomyelitis and the various forms of acute ascending myelitis, the differentiation is still less difficult if one keeps well in mind the specially prominent characteristics of acute ascending paralysis. These are the rapidly advancing motor character of the paralysis, the comparative sensory phenomena, the unaltered electrical reactions, the absence of typical muscular atrophy, the non-involvement of the sphincters and the almost total want of fever and febrile manifestations. In infantile palsy the average age of the patient and the peculiarly localized muscular distribution of the paralysis are important aids in making a differentiation. The sensory phenomena, the involvement of the sphincters and the reflex changes distinguish quite clearly an ascending myelitis.

The frank recognition of the toxemic origin and nature of both the typical and atypical forms of Landry's paralysis, will make the way clearer for a rational mode of treatment. The two prime indications are to support the patient's vitality and to eliminate the poison as quickly as possible. For the former purpose, judicious stimulation is demanded. Alcohol, strychnia and the more diffusible stimulants may be cautiously used. For the latter purpose the skin, bowels and kidneys should be aroused into unusual activity. Diaphoresis.

provoked by the use of the hot pack, catharsis with calomel or other rapidly acting and non-exhausting purge, and diuresis with diuretin or some similar agent are all to be employed as promptly as possible. The few remedies that have been tried and recommended in this disease can not be very highly lauded. They have been tried in far too small a number of cases or else they have been given on too much of a mere empirical basis. Such remedies, however, are the salicylates, benzoate of sodium and large doses of ergotin (gr. ii every hour). As might have been expected, mercury and the iodid of potassium have been experimented with. With a history of syphilis, they are, of course, indicated. Soltman reported a case in a 11-year-old girl cured by vigorous inunctions. Less desirable, if not positively irrational, would seem to be such violent measures as strong counter-irritation to the spine with mustard and the actual cautery. Such have been tried, however, and found wanting. Special symptoms, such as the dysphagia, for instance, call for special measures, such as the rectal or nasal tube. In fine, the treatment of Landry's form of intoxication of the nervous system narrows itself down to careful stimulation, rapid, non-exhausting elimination and increased nutrition with absolute rest in bed for a more or less prolonged period.

100 State Street.

SURGERY OF THE STOMACH.*

WILLIAM H. WATHEN, A.M., M.D., LL.D.
Professor of Abdominal Surgery and Gynecology in the Kentucky School of Medicine; Surgeon to the Kentucky School of Medicine Hospital, the Louisville City Hospital and St. Anthony's Hospital.
LOUISVILLE, KY.

We have learned from recent surgery of the upper abdominal cavity that in very many cases diagnosed chronic dyspepsia, and treated hygienically, dietetically and medicinally without permanent relief, the symptoms are not the result of functional trouble or of chronic gastritis that changes the chemistry of the gastric secretions, but are the result of pathologic conditions that interfere with the normal physics of the stomach and duodenum, because of organic and mechanical changes in these organs, caused by gastric or duodenal ulcer, with frequent perigastric inflammation, adhesions and contractions, which predispose to the development of cancer.

While our learned pathologists, in necropsies of patients dying in the large hospitals of the world, tell us that about 5 per cent. have active gastric ulcer, or the scar of an old one, and that in 50 per cent. of these there are perigastric adhesions, that from 1 per cent. to 3.5 per cent. of all deaths are caused by gastric cancer, and that approximately 40 per cent. of all cancers occur in the stomach, they are silent when we inquire, how are we to prevent this intense suffering and these untimely deaths?

It seems that this has been left to the combined surgical pathologist and clinician, who has learned more from *sectio in vivo* than from necropsies. He has learned, by timely operation for gastric ulcer and perforation, pyloric retention and obstruction, and perigastric adhesions, that he may not only cure his patient of gastric hemorrhage, perforation, intense pain and dyspepsia, but may prevent the development of cancer of the stomach, to which these irritations, by interfering with nutrition and resistance, predispose. Notwithstanding these facts, the life-saving principle of early diagnosis of organic lesions and timely surgical interference is not generally appreciated by most of our good surgeons and physicians, the work in its excellence being mainly confined to but comparatively few men (Robson, Mayo, Murphy, Ochsner, Mikulicz, Czerny, Moynihan, etc.), and even with those who are doing most to evolve what is in the interest of the immediate relief and subsequent life of the patient, there is no consensus of opinion in all instances as to when an operation should be performed, or which of the many operations devised accomplishes the most satisfactory results.

Professor von Mikulicz operates on about four times as many cases of cancer of the stomach as he does of gastric ulcer, while the reverse is practically true of Dr. Mayo; hence von Mikulicz takes this as the measure of the relative number of benign and malignant diseases of the stomach in Germany and the United States. In view of the fact that about 5 per cent. of all necropsies show active gastric ulcer, or the scar of an old one, while in the Vienna Hospital in 61,287 necropsies gastric cancer was found in but 1.5 per cent., I am inclined to the opinion that von Mikulicz's operations are not always timely, cancer having developed in an ulcer or about its cicatrix, for the cancer is usually the subsequent change in the ulcer.

Experience in gastric surgery, when the profession practically appreciates the significance of early diagnosis and timely operation, will convince us that in all countries there is about the same relative ratio in the number of cases of gastric ulcer and gastric cancer. Dr. Mayo diagnoses his cases and operates in the pre-cancerous stage, while von Mikulicz often loses the golden opportunity and operates after cancerous invasion; hence his immediate and subsequent mortality is much greater than in Mayo's cases.

Gastric and duodenal ulcer, with the numerous and varied complications, will finally sustain the same comparative relation to the surgeon and physician that appendicitis does to-day, and the same benefits will be derived from early diagnosis and timely operation. Only a few years ago, most patients with appendicitis refused to be operated on, having been told by many of our physicians and surgeons that the disease could be cured by saline purgation, opium and hot or cold applications. The reverse is true now, and in the near future the same will apply with equal emphasis to surgery of the stomach.

While gastric ulcer and cancer may occur in any part of the stomach, they are usually found in the pylorus, where there is an abundance of lymph vessels and glands, the cancer succeeding the ulcer, though often it does not do so for several years, many cases of ulcer being apparently cured. In the upper or lesser curvature of the stomach the lymph spaces and glands are abundant, and extend through the base of the gastrohepatic omentum and in the stomach tissue to the cardia, with the current from right to left, but in the lower or greater curvature, the lymphatics do not extend far to the left through the gastrocolic omentum, and the current is probably toward the pylorus, as seems to have been demonstrated by Cuneo. It is important that we should know, in pylorectomy and partial gastroectomy, how much of the stomach and the omenta to remove to destroy the cancer-bearing areas and infected lymphatics, except the isolated area of lymphatics in the dome above the gastro-splenic ligament; for the exact line of separation between gastric ulcer, with infiltrated or scar tissue, and cancer can never be positively known.

---

* Read before the Louisville Clinical Society.

Until recently and even now, with few exceptions, nearly all chronic diseases of the stomach and upper abdominal cavity have been treated empirically by giving such medicinal, dietetic and hygienic treatment as the subjective symptoms seemed to indicate, occasionally analyzing the stomach secretions so as to supply any absent chemical constituent. Hence the frequent organic lesions that yield only to surgery were not diagnosed until advanced cancerous development, or until the disease had progressed too far to be cured by either the physician or the surgeon; and as we daily see in our mortuary reports, these patients fill an untimely grave. In the diagnosis of disease of the stomach, analyses of its contents are never conclusive until we have a correct appreciation of the value of the subjective and physical symptoms, caused by organic lesions and mechanical changes, both gastric and perigastric, including diseases of the gall bladder, bile ducts, duodenum and pancreas. We must learn to make a pathologic and surgical diagnosis, such as we are now able to do in diseases of the fallopian tubes and other pelvic structtures, and the appendix; and this the abdominal surgeons will very soon teach us. The excellence of the work in pelvic surgery made possible the grand achievements of surgery in the lower abdominal cavity, including diseases of the appendix, and the perfection of this work has extended to and is perfecting the surgery of the upper abdominal cavity. From the pelvis we have gone to the appendix and to the intestines. kidneys and ureters, then to the gall bladder and bile ducts; and now we have reached the stomach and the pancreas with more encouraging results than when we approached the other organs and structures.

While a knowledge of the pathologic changes in any disease is necessary to enable us to obtain the best results in the surgical treatment, time will not permit me to enter into an extended discussion of the symptoms and physical changes that indicate the necessity for a surgical operation in diseases of the stomach, so I will briefly mention but a few facts that may enable us to make an approximately correct diagnosis, and to judge of the necessity for surgical interference.

In acute ulcer, hemorrhage or repeated hemorrhage may occur with or without premonition, sometimes causing profound shock and alarming symptoms, from which the patient usually quickly recovers without medical or surgical aid. The blood is vomited and also passed through the bowels in the feces, which confirms the diagnosis. The hemorrhage may continue in diminished quantity and frequency, and the ulcer assume the chronic form; it may then entirely cease or become profuse and quickly fatal by the necrosis of a large gastric or perigastric artery. Gastric perforation may occur in the acute, subacute or the chronic ulcer. If in the acute ulcer the perforation is sudden, of large size, allowing the stomach contents to pass freely into the peritoneal cavity, causing profound shock and intense pain, with board-like rigidity of the recti muscles, such as we have in acute appendicitis; even when the pain and shock are relieved by morphia, the rigidity of the muscles remains. We may have similar symptoms in duodenal perforation, gall-bladder rupture or acute pancreatitis, but a differential diagnosis is not essential, for in either instance a surgical exploration should be promptly instituted. Perforation in the subacute ulcer may show more premonitory symptoms, or may penetrate the walls as quickly, but as the opening is small, inflammatory exudation and plugging usually prevent the extravasation of stomach contents, and very soon the opening is closed by firm adhesions, often leaving the stomach in a permanently crippled condition, such as we find in most cases of chronic gastric ulcer. A rupture through the posterior wall may not be followed by extravasation of the stomach contents, because the anatomic conditions admit of quick adhesions, the peritoneal surfaces being in apposition, but in these cases we may have subphrenic abscess. We have retention in chronic gastric ulcer, because the circular fibers of the pylorus spasmodically contract, when pain is induced by the efforts of the stomach to force the food into the duodeum; or because of organic changes that contract the opening at the gastroduodenal union; or because of cicatricial contraction in the body of the stomach, or perigastric adhesions that interfere with its normal motility. In either of these conditions the stomach will probably become dilated and may be hypertrophied, caused by the greatly increased labor entailed on it.

Pain will be a frequent symptom. The macerated food that the stomach can not force into the duodenum will decompose and cause painful irritation, and vomiting often results because of reversed peristalsis, such as we find in any part of the alimentary canal when an obstruction is not overcome by the normal peristaltic force. A stomach that at all times contains residual food in a decomposed condition can not be restored to its normal function except by a surgical operation that will cause free drainage. The diagnosis may be made positive by giving the patient no food for many hours, and then removing the stomach contents through a tube. If there is no interference with drainage, the stomach will be empty, otherwise there will be retained decomposed and bad-smelling residuum. Dilatation of the stomach and hourglass contraction may be outlined, and a correct diagnosis made by inflating the cavity with air pumped gradually in through a bulb syringe watching the changes that occur as the stomach is distended; and well-developed single or multiple hourglass contraction with pyloric stenosis may also be diagnosed by filling the stomach with water and then removing it. If 30 ounces be used, probably not more than from 20 to 25 ounces will come away through the tube, the other being left in the pyloric saculus; or if the stomach be thoroughly cleansed by lavage, and within thirty minutes the tube be again introduced, there will be an offensive discharge which had returned to the cardiac saculus from the pyloric end. While an excess of hydrochloric acid in the gastric secretions may be the cause of gastric ulcer, and while the hydrochloric acid may be diminished or absent in cases of cancer of the stomach, hyperchlorhydria and hypochlorhydria are of secondary importance as diagnostic factors.

In cancer of the stomach, chemical and microscopic examinations of stomach contents, of feces, urine and blood, are only of greatest value when the disease has passed the operable period, and often the beginning or the extent of cancerous invasion can only be positively known by an exploratory incision. The well-trained surgeon will commit no evil here. for if the disease is in the inoperable stage, the incision will cause but little trouble, and if not, there will be a malignant or other organic involvement that indicates the necessity for surgical treatment. The incision for exploration should be short, and if the peritoneum be sutured by fine catgut, the fascia by silver wire or silk, and the skin also by fine catgut, the patient may leave the hospital in a few days and not remain in bed.

Osler recommends that an exploratory operation should be more frequently advised by the physician, and his opinion on this subject is entitled to much consideration, because of the extent and excellence of his work in cancer of the stomach.

Pain and vomiting and the perception of a tumor in the stomach are frequent symptoms in gastric cancer, Mayo Robson's statistics showing pain in 86.6 per cent., vomiting in 85.3 per cent., and tumor in 76.6 per cent.; and Fenwick says a tumor may be palpated in the body of the stomach in 81 per cent. of cases, in the pylorus in 71 per cent., and in the fundus in 55 per cent. While gastric ulcer may cause rigidity of the recti muscles, this is not true of cancer, and if the tumor is not situated too high, or can be forced down by full inspiration, it may be palpated with comparative ease. A well-defined tumor of the stomach does not always indicate malignancy, for patients with tumors at or near the pylorus have been permanently relieved of symptoms by a gastroenterostomy, and tumors attached to the abdominal walls with infiltration have disappeared when adhesions were separated, though a diagnosis of cancer had been made before and after the operation. The surface of a benign gastric tumor is regular and even, but the malignant tumor is irregular and nodular. Gastroenterostomy or the removal of adhesions never cures cancer, but may cure patients supposed to be suffering with cancer, who may otherwise have finally died of this disease. This error in diagnosis may explain the false assumption that gastric cancer is relatively increasing in frequency, for many of these patients having died without operation, were recorded cancer, no necropsy being made.

The following summary will indicate most of the diseased conditions of the stomach and duodenum, with their varied complications, that may be treated surgically:

1. Hemorrhage from ulcer.
2. Gastric or duodenal perforation.
3. Chronic gastric or duodenal ulcer.
4. Benign pyloric stenosis and retention.
5. Perigastric adhesions and contracted stomach.
6. Gastric cancer.

Hemorrhage in acute gastric ulcer, though profuse and with alarming symptoms, is usually self-limited and needs surgical treatment only when continued repetition shows that it will not be controlled by treatment of the physician. In such event, the bleeding may yield to stomach drainage at the most dependent part, which may be best accomplished by gastroenterostomy. The treatment applied immediately to the ulcer after opening the stomach, or by excision of the ulcer, has not been successful, and is also contraindicated because of the relatively high mortality, and because the ulcer is often multiple.

While some of these patients may permanently recover, other cases pass gradually or imperceptibly into the chronic stage, and we may find them many years later with chronic gastric ulcer or cancer, with abundant n tr mplications. But in acute ulcer, a far ıan hemorrhage is the large perfora- ır, through which the contents of the um may freely flow into the per- using death by diffuse suppurative peritonitis, unless promptly operated on. These patients should be operated on both promptly and quickly, *for they will not recover from a delayed or prolonged operation or a too profound anesthetic.* Any stomach contents or pus that may be in the immediate vicinity of the perforation should be gently sponged away, but I doubt if further sponging will benefit the patient, and its employment may greatly impair the peritoneal resistance. *If the infection is streptococcic, the patients will all die under any treatment;* otherwise many cases with diffuse suppurative peritonitis may recover, if, after suturing the perforations, a stab opening be made in the lower abdomen and drainage instituted through a tube introduced into the uterorectal pouch, or the vesicorectal pouch in the male.

Any attempt to cleanse the peritoneal cavity by persistent sponging may so destroy the protecting endothelium as to encourage rather than prevent the growth of pathogenic bacteria, and thorough irrigation with saline solution may do no good, and may do much harm. If the infection is not streptococcic, it may not be primarily virulent, and the pus may soon become practically sterile if the cavity is allowed to drain itself from the most dependent part, and we do not irritate and impair the resisting powers of the peritoneum.

In chronic gastric ulcer, with or without pyloric stenosis, we should establish drainage that will allow the stomach contents to pass freely into the intestine with the least possible effort, and great relief will promptly follow. *If there is no organic obstruction in the pylorus, but retention of stomach contents because of spasmodic contraction caused by ulcer in this locality, then the only method we can logically employ is gastroenterostomy,* but when the ulcer soon heals, complications may arise when the food again passes freely through the pyloric opening. The gastrojejunic opening may then contract, leaving the intestine attached with impaired peristalsis.

In organic obstruction in the pylorus, free stomach drainage is also the only rational treatment, and of the various methods practiced, gastroenterostomy is the one generally accepted by our best surgeons, and seems to have given the best immediate and subsequent results, with the lowest mortality. Theoretically, we might prefer drainage at the pyloric end of the stomach by some of the various operations devised, but the results are not in harmony with the theory. Pyloric divulsion by the method of Loreta and Hahn has proven unsatisfactory, and the results are never permanent; nor do we feel much encouragement from the results of the Heineke-Mikulicz pyloroplasty, or its modification by Richardson, or of the submucous pyloroplasty of Koeppelin and Jaboulay, where the incision is made to but not through the mucosa; or the gastroduodenostomy of Jaboulay and its modifications by Duranti and Henle. Probably the operation by Finney, for drainage at the pyloric end, known as Finney's pyloroplasty or gastroduodenostomy—which should be more correctly called pylorogastroduodenostomy—will give better results; but this is not suited to many cases, because of the necessity of dealing with the frequent perigastric adhesions, to enable the operator to unite the surfaces without tension. As this operation was performed only a few years ago, more time is needed to prove its continued success in drainage.

While gastroenterostomy, devised by *Nicoladoni* in 1881, is now the operation of general election, there is no consensus of opinion of just how and where the anastomosis should in all cases be made, but good results are only obtained by drainage through a gastrojejunic opening. It is agreed, however, that the union should be made at the bottom of the stomach, just anterior or posterior to the attachment of the gastrocolic omentum, equally good results having been claimed by either method. The anastomosis may be made by the suture or the Murphy button, the same operator sometimes using one and again the other; but the tendency is in favor of the suture, except in specially selected cases, Murphy uses the button; Ochsner and Mayo have used both button and suture, but generally the latter. Czerny uses the button, and believes it is efficient in preventing the vicious circle. The bone-bobbin of Robson, and other similar devices, are seldom of any use when the surgeon becomes adept in using his needle.

In anterior gastroenterostomy, where an immediate gastrojejunic opening is not required, I believe the McGraw ligature method will finally be recognized as the simplest and the best, and there is no reason why the opening should not be as large as by other methods and remain as long patulous. It can be done quickly, and the danger of infection is reduced to a minimum, neither the stomach nor intestine being incised.

The retention of the Murphy button in the stomach will seldom occur if the incision be correctly made at the base of the stomach and its retention in the bowel is infrequent. The German "circulous viciosus," for the prevention of which we formerly did a jejunojejunostomy, is generally prevented by our modern methods, as we now seldom do the interoenterostomy of Wölfler, or the modification of Roux between the afferent and efferent limbs of the attached intestinal loop, or its modification by Fowler, who occludes the afferent limb with silver wire. The Mikulicz and Czerny recent modification in posterior gastroenterostomy, by which they eliminate the afferent loop, may yield excellent immediate and subsequent results, as the jejunum is attached to the stomach only three or four inches below its emergence under the mesocolon and on a level with the base of the stomach. If this operation is to be finally the operation of election, it may not only eliminate the possibility of a vicious circle, but also prevent jejunic ulcer by alkalizing the gastric contents with the bile and pancreatic secretions. While gastroenterostomy is indicated in hourglass contraction of the stomach, the operation alone will not be successful unless the pyloric saculus is very small, but it should be preceded by a gastroplasty or a gastrogastrostomy, and then the attachment of the intestine must be made to the pyloric end, otherwise drainage can never be complete and there will be retained in the stomach decomposed and foul-smelling food and secretion.

In all operations for gastric contractions, the stomach should be carefully examined to its fundus, for we may have a saculus at the dome, and then drainage from the pyloric saculus may not greatly, if at all, benefit the patient.

As these contractions may be caused by perigastric fibrous bands, the deformity may be removed by dividing them or dissecting them off. Perigastric adhesions may change the normal relation and physiologic action of the stomach, duodenum, gall bladder and bile ducts, and should be separated or divided as completely as possible, so as to establish an approximately correct relation. While the separated adhesions may possibly re-form, they will not do so to the same extent, nor will the new adhesions as greatly interfere with the physics of these organs. In rare instances the separation of adhesions may cure the patient without stomach drainage, as in a patient I recently operated on. He had several years previously suffered with either gastric or duodenal ulcer, and had symptoms of obstruction and adhesions, which caused constant pain. No evidence of the scar of an old ulcer could be found, and the gall bladder and bile ducts were normal, but extensive gastroduodenal adhesions had caused partial pyloric obstruction by drawing the upper part of the duodenum against the pyloric end of the stomach, the normal relation being restored when the adhesions were removed.

In considering the surgical treatment for cancer of the stomach, we must not be influenced by the results of Billroth or his immediate followers, or, in fact, by any results except in patients recently operated on; nor must we see any value in the older statistics, further than to show by comparison with present methods and results, an evolution that has removed most of the former dangers. Billroth's operations for pylorectomy and gastrectomy were bloody and prolonged, most of his patients leaving the operating table in profound shock, from which but few recovered. But, then, the histology, physiology and anatomy of the stomach and perigastric structures were not practically appreciated. This is especially true in relation to the blood vessels and lymphatics of the stomach and the gastrohepatic and gastrocolic omenta; hence we did not know how easily pylorectomy and partial gastrectomy could be made nearly bloodless operations, or how much of omenta and stomach should be removed or the direction of the line of incision in resections, or the value of closing the end of the duodenum and the stomach, and establishing drainage through a gastrojejunic opening. Mayo's mortality in the various operations for cancer of the stomach in 109 cases is 15.5 per cent.; and in 41 radical operations on the pylolric end of the stomach, 4 for ulcer and 37 for cancer, 8 died, but in his last 11 he has had no death.

In many cases of cancer of the stomach, the disease is so extensive and so many complications have developed that a radical operation for permanent relief is contraindicated, but in these cases much relief may be afforded by a gastroenterostomy, where enough healthy stomach tissue can be utilized, or, if this is not possible, pain may be greatly relieved and life prolonged by a gastrostomy or jejunostomy, putting sufficient food in the jejunum through a Jaques catheter. The mortality in gastrostomy and jejunostomy is practically *nil*, and Mayo Robson's recent mortality in posterior gastroenterostomy for simple diseases is 3.9 per cent and for cancer but 5 per cent. In pylorectomy or partial gastrectomy in benign pyloric obstruction, gastroduodenostomy can never be an operation of general election, and in cancer it should never be attempted. Theoretically, it would seem to possess some advantages over gastroenterostomy, but practicallly it does not. and the increased mortality contraindicates the operation. While the open end of the duodenum may sometimes be brought without tension to the lower part of the remaining stomach and be anastomosed. this is seldom possible because of the firm inelastic adhesions which can not be entirely removed, and where there is tension there can be no safe union. These objections do not apply to gastroenterostomy, and the gastrojejunic opening will remain permanently patulous in either anterior or posterior union. Patients have recovered from the operation for total gastrectomy and lived for one or two years, but I do not believe the operation is justifiable, based on our knowledge of the location and behavior of gastric cancer. Cuneo's observations on the lymphatic currents were utilized by Hartman when he fixed the line of section in partial gastrectomy, and these facts have been accepted by our best surgeons.

In the radical operation for simple pyloric stenosis with hypertrophy, it has been suggested by Rodman that extensive resection beyond the lymph nodes may give better permanent results, because of the removal of pyloric ulcer and cancer areas, except in the dome and cardia. In cancer of the dome of the stomach or the cardia, total gastrectomy is a difficult and dangerous operation, with nearly 100 per cent. mortality, and if primarily successful will not give more continued relief than gastroenterostomy. In cancer of the body of the stomach a gastroplasty may be indicated if seen in the earlier stages. While the stomach is as abundantly supplied with blood vessels as any organ of the body, and anastomosis as perfect as in the vessels supplying the uterus, and in a degree similar, hemorrhage is easily controlled in radical operations by ligating the principal branches beyond the lines of incision. If the coronary branch of the gastric, the pyloric branch from the hepatic and the right and left gastroepiploica be ligated at the correct place, hemorrhage will not be profuse in radical operations at the pyloric end of the stomach extending up the lesser curvature nearly to the cardia. It must be remembered that the blood is derived from each of the three branches of the celiac axes—the gastric, splenic and hepatic. In partial gastrectomy I see no advantage in Mayo's curved incision with the convexity toward the dome, but prefer using the long straight forceps, and making a direct incision from the greater to the lesser curvature. This as successfully removes the infected area, and gives a broader and better stomach surface for jejunic attachment.

THE PREVENTION OF TETANUS.

DANIEL N. EISENDRATH, A.B., M.D.
Adjunct Professor of Surgery, College of Physicians and Surgeons; Attending Surgeon to Cook County Hospital.
CHICAGO.

Much has been written during the past ten years concerning the symptoms and treatment of tetanus, and especially the frequency with which it followed all varieties of punctured wounds. Little, however, has been written as to definite methods for the prevention of this dread disease, and it has always seemed to me that this aspect has not been sufficiently dwelt on. We usually associate tetanus with Fourth of July wounds, but it is almost as frequent after punctured wounds received by rusty nails or pitchfork injuries as after blank cartridges. Why these three classes of injuries should be followed by tetanus can not be explained on any other ground than that in the case of blank cartridges the latter itself is free from tetanus, but that the hand or foot or face, which are the most frequent sites of infection, are more or less covered with street dirt containing tetanus bacilli, and that the blank-cartridge wound furnishes the ideal conditions for the development of the tetanus bacilli. These conditions are a more or less completely closed wound, containing a foreign body in the shape of a portion of the cartridge.

It has been shown experimentally that the pathogenicity of the tetanus bacillus is increased by irregular wounds where there is more or less necrosis, or in the presence of a hematoma, especially if a foreign body be present. In the case of rusty nails one does not have to seek far to explain the origin of tetanus after such wounds. It is not the rust on the nail, as has been generally thought, but the fact that the nail is covered more or less with dust and street dirt, and that the sole of the foot or the palm of the hands are, as in the case of a blank-cartridge wound, in none too clean a condition, being almost invariably covered with dirt at the time of the reception of the injury. In the case of pitchfork wounds a somewhat similar origin can be demonstrated. It is well known at the present time that the tetanus bacillus is found under normal conditions in the intestine of horses, and that the spores are present in horse dung, manured gardens, street dirt and poorly built wells. It does not require a great stretch of imagination to see how a pitchfork, either covered with street dirt or horse dung or garden earth, can carry into a punctured wound many tetanus bacilli. It has been amply shown that the blank cartridge itself does not contain tetanus bacilli. In the exhaustive article on "Fourth of July Casualties," published in The Journal of the American Medical Association, Aug. 29, 1903, five investigators are quoted who have examined 759 blank cartridges, bacteriologically, without finding tetanus bacilli in one.

My principal reason for writing this article has been to call attention to the fact that if a punctured wound which has been inoculated with tetanus bacilli be treated sufficiently early by methods which are based on the knowledge of the bacteriology of the disease, we can absolutely prevent the development of tetanus in every case. The tetanus bacillus, I need scarcely mention, is an anaërobic organism, and is surrounded by ideal conditions for its growth in punctured wounds. After the foreign body, whatever it may be, has penetrated the skin and underlying soft parts, the edges of the wound of entrance are rapidly closed by wound secretion, and we have a closed cavity, as I have been able to demonstrate on a number of occasions, devoid of oxygen, and an ideal place for the development of the tetanus bacillus. Add to this the necrosis and blood clots, and it requires only a short time before the symptoms of tetanus appear. When we consider that human beings, mice and guinea-pigs, are exquisitely sensitive to the toxins of tetanus, and that it requires only 1/100,000 to 1/10,000,000 of a cubic centimeter of tetano-toxin to kill a mouse, we can readily understand how a few tetanus bacilli can produce the necessary amount of havoc within a comparatively short space of time.

The period of incubation varies somewhat, according to the severity of the infection. According to Bruner, when the incubation period was one to five days, nine cases died and one recovered; when the period of incubation was five to ten days, eighteen died and eight recovered; when it was ten to twenty days, none died, and six recovered. From this we can deduce that the longer the period between the infliction of the injury and the appearance of the symptoms, the less severe the case. Many of the cases of tetanus which have responded to the tetanus antitoxin have belonged to the subacute variety.

In regard to the prospects of recovery after the development of tetanus, one needs only to bear in mind the large percentage of deaths, even after the use of antitoxin and medicinal remedies, such as morphin, bromids, chloral, etc. Ullrich has lately collected 19 cases, in which the Behring tetanus antitoxin was injected between the second and the fifth days. Of the nineteen, 9, or 47.3 per cent., recovered, and 10, 52.6 per cent., died. Including 53 cases treated during the same period of the appearance of the symptoms by other antitoxins, there are 72 cases, of which 39 (53.8 per cent.) were healed, and 33 died (45.5 per cent.) Twenty-three of these had an incubation period of ten days. Of these, 16 were healed (59.7 per cent.), which verifies what I have stated above, that the percentage of recoveries improves when the antitoxin is used late, because these are the milder cases; that is, those with longer periods of incubation. Of 15 cases collected by Kupnik, treated symptomatically with chloral, etc., 53 per cent. recovered. These were, in all probability, subacute cases.

In regard to the manner in which the tetanus toxin reaches the nerve-centers, there can no longer be any question that it is along the nerve trunks from the infected part, causing the characteristic symptoms through their toxic action on the nerve-centers of the pons and medulla, and then acting on the cranial nerves arising from this portion of the brain, thus explaining the early involvement of the fifth nerve. We thus see that the curative treatment of tetanus leaves much to be wished for, and we can only hope to reduce the high mortality of the disease through prophylactic treatment.

The technic which I am about to give can be summed up briefly as consisting of converting a closed wound filled with necrotic débris, blood clots and foreign bodies (blank-cartridge wads), into an open one, so that there can not be the least corner of it in which a tetanus bacillus finds its necessary conditions for growth. Before referring to my own work, let me call attention to a case which has been far more thoroughly worked out than any of those which I have to report, published in the *Annals of Surgery* of the present year, by J. B. Bain of the Massachusetts General Hospital. It is the first case in which tetanus bacilli were ever found before the development of symptoms of the disease, thus proving the theory that prophylactic treatment can actually be carried out, even though tetanus bacilli are in the wound, and can be demonstrated as such positively by bacteriologic tests. The case is as follows:

A boy of thirteen was shot in the palm of the right hand with a blank cartridge July 3, 1902. A punctured wound was present, with blackened edges and surrounded by an area of powder-stained tissue. Every bit of blackened skin and tissue was removed; the wound thoroughly disinfected. All of the tissue, together with particles of the wad and powder grains, was placed in culture tubes and sent to the laboratory to be examined for tetanus bacilli. The latter were isolated in pure cultures. The patient made a prompt recovery without the development of any of the symptoms of tetanus.

A somewhat similar case has been reported lately by Ullrich, quoted above, in which a man's arm had been torn off at the shoulder joint. The patient was a diabetic, and the wound became infected with the pyocyaneus bacillus. No examination was made for tetanus bacilli. On the third day after the injury a prophylactic dose of antitetanic serum was given. No symptoms of tetanus appeared until two months after the injury, when he had twitchings in the face, pain on mastication, trismus, hyperesthesia, sweats, etc., these symptoms continuing for two months, and were interpreted—as I believe to be perfectly justifiable—as having been tetanic.

During the past four years I have had occasion to treat eight cases of blank-cartridge and punctured wounds, with the direct view of preventing the development of tetanus. Of this number five were blank-cartridge wounds, three involving the fingers or palm of the hand, one the thigh, one the eyelid, and three cases were punctured wounds—one due to a pitchfork entering the ankle joint, and two rusty nail wounds penetrating the entire thickness of the foot from the sole of the foot to the dorsum. One of these cases described in detail will illustrate the treatment applied to all of them.

A boy 10 years of age was shot in the palm of the hand while handling a toy revolver. Four days later there was the usual swelling in the palm of the hand and discoloration of the skin around the wound of entrance.

As in all of the above cases, where the wounds contained either blank-cartridge material or dirt which had been carried in by rusty nails or pitchforks, I would only consent to assume the responsibility in the case when the parents or the patient himself consented to the administration of an anesthetic in order to thoroughly cleanse the wound.

The cleansing was done in the present case in the following manner: An Esmarch constrictor was applied around the middle of the arm well above the point of infection, for the reason that one can only deal satisfactorily with any of the forms of infective wounds of the extremities when the tissues are bloodless, so that one can see the extent of the infection without constantly having the field of operation flooded with blood. After thorough disinfection of the entire forearm and hand by the usual methods, an incision was made directly over the palm of the hand and the entire tract of the blank cartridge followed. It extended from the middle of the palm of the hand to the base of the first phalanx of the middle finger. All of the connective tissue of the hand and the muscles lying between the metacarpal bones, as well as the tendon sheaths, were found to be encrusted with particles of powder, and the tract itself contained about a teaspoonful of the typical blackish-green pus which one encounters in this class of wounds. After wiping away the pus, a tissue forceps and scissors were employed to cut away every particle of powder-stained tissue, as only in this manner can the wound be thoroughly cleansed. After this had been done, the edges of the wound having been held apart during the entire procedure by means of retractors, the skin along the edges of the tract, and especially around the wound of entrance, was excised, so that as far as the naked eye could determine, there were no blackish particles left in the wound. At the distal end of this suppurating tract a blank cartridge was found which showed a typical paper wad. Unfortunately cultures were not made at the time of the operation. The entire wound area was now swabbed with pure carbolic acid, followed immediately by the application of 96 per cent. alcohol, and packed with gauze, and a wet 1 to 1,000 salicylic acid dressing applied, and the hand was placed on a splint. No sutures were employed. The wound was allowed to heal by granulation. Immediately after putting the patient to bed, 20 cubic centimeters of tetanus antitoxin were injected to neutralize any of the tetanus toxin which might have been absorbed prior to the time of operation.

The after-treatment consisted in irrigating the wound daily with mild antiseptic solutions (1 to 1,000 salicylic acid and peroxid of hydrogen), and was then repacked. The patient made an uneventful recovery without showing any symptoms of tetanic intoxication.

A similar treatment was employed in all of the other cases, the first five not being given the prophylactic dose of tetanus antitoxin, but in spite of this making as prompt a recovery as the case that has been detailed.

SUMMARY.

The points which I desire to emphasize in the prophylactic treatment are the following:

1. Early and thorough exposure of every portion of the tract which has been infected by the blank cartridge

or instrument which caused the punctured wound, retracting the edges, so that the disinfection and removal of the infected tissues can be done under the guidance of the eye.

2. Prophylactic injections of tetanus antitoxin to aid the organism in combating whatever toxins may have been absorbed prior to the time of operation.

3. This thorough disinfection can only be carried out under anesthesia, either local or general, and when the parts are rendered bloodless by the application of a constrictor.

4. The blank cartridge itself does not contain tetanus bacilli, but undoubtedly carries them in while penetrating the skin.

5. The instruments which cause punctured wounds either are covered as described above with tetanus bacilli or the manure of horses, etc., and are thus carried into the wound.

6. Our only hope in reducing the high mortality of tetanus is in a thorough application of such radical measures as have just been described.

SUPRAPUBIC PROSTATECTOMY UNDER NITROUS OXID ANESTHESIA.*

JOSEPH WIENER, Jr., A.B., M.D.
Adjunct Attending Surgeon, Mount Sinai Hospital.
NEW YORK CITY.

That the removal of the prostate gland is the ideal surgical procedure in the treatment of prostatic hypertrophy is now very generally recognized. The chief contraindication to the performance of a prostatectomy up to the present time, according to the consensus of opinion, has been the danger resulting from the administration of ether or chloroform. Many surgeons have hesitated to offer some of their old prostatic cases the benefits of the operation on account of the presence of cardiac, nephritic or other lesions. It is in the hope of widening the field of usefulness of prostatectomy, and of extending the splendid benefits of the operation to patients who have heretofore had the advantage only of palliative operations, that this paper has been prepared. The cases which form the basis of the paper are, so far as I have been able to ascertain, the first cases of prostatectomy that have been performed without the use of ether or chloroform.

CONTRAINDICATIONS.

The chief contraindications to the performance of prostatectomy have until recently been the dangers resulting from first, the general anesthetic; second, hemorrhage; third, shock. By the use of laughing gas the great objection of a general anesthetic is at once removed. If, in addition, we do rapid work, then all three of the objections are removed. A prostatectomy done under nitrous oxid, in from eight to fifteen minutes, is not accompanied by any dangers from the anesthetic; the hemorrhage in those few minutes is very moderate and there is no shock. The patients are conscious even before the dressings have been applied. There is no vomiting; the pulse remains normal, and in a few minutes fluids are taken by mouth. Many surgeons have held that a man unfit for general anesthesia is unfit for prostatectomy. In view of our experience with laughing gas, are we not justified in asserting that this view is erroneous? Is it not likewise erroneous to hold that a man who can not take ether or chloroform should have a Bottini operation done? Is he not very much better off if he has a prostatectomy done under laughing gas? Diabetes is still considered by most surgeons an absolute contraindication to prostatectomy. So it probably is, if the operation takes forty-five minutes or longer, and if ether or chloroform is used. But if the suprapubic operation be done in ten minutes without ether or chloroform, then diabetes is no contraindication. Two of my cases were diabetics, and one of them had large amounts of glucose in the urine at the time of the operation and during the after-treatment. Yet both these cases recovered. A badly infected bladder is often given as a contraindication. In one of my cases (Case 5) there were daily chills as a result of a severe cystitis, and the urine contained a large amount of pus. After draining the bladder for ten days, the prostate was removed *in toto,* and the man made a splendid recovery. And that is just one of the advantages of the operation—that we can, in badly infected cases, first relieve the cystitis, and then, through the same opening, remove the prostate in a very few minutes. Again, we are told that old age is a bar to the removal of the prostate. The patient just referred to was 75 years old; another man was 82 years old. It is a curious fact that these two very old men made a more rapid recovery than the younger men. What, then, are the contraindications for the performance of a suprapubic prostatectomy under laughing gas? Candidly, I do not know. What I do know is that there are very few, even old diabetic cases with severe infections of the bladder, that can not be cured by the operation. This statement may seem extreme, but a careful study of the cases narrated below will. we believe, confirm its truth.

Many objections have been raised to the operation. Chief among them are severe hemorrhage, the infection of the raw surface left by the removal of the prostate, poor drainage and the difficulty of the operation. Chief among the objectors are those who do not perform the operation. As regards hemorrhage, I have never experienced a severe one, nor have I seen it at the hands of others. The infection of the raw surface at the base of the bladder we would expect, at first sight, to occur much oftener than it does. I do not know of a single case in which this complication was encountered. The use of urotropin and of bladder irrigations effectually prevents its occurrence. The opponents of the operation tell us that we are draining uphill. So we are. But by using syphon drainage, together with daily flushings of the bladder, we find that our drainage, from the very time of operation, is excellent. The entire wound is left open, and we never have any difficulty in draining it. The same objection to uphill drainage might be raised in all our operations on the appendix and gall bladder. It would be just as valid as it is in regard to the bladder. The difficulty of performing the operation has been raised as an objection. We are told that great strength is required to shell out the prostate rapidly. The advantages of removing the gland in one piece are twofold: the hemorrhage is less and one is sure of having removed the entire gland. That a great deal of strength is generally required I can testify. The objection, however, does not apply to the operation, but to the operator.

AGE OF PATIENTS.

The youngest of my patients was 57 years old, and the oldest 82 years. The average age was 69 years.

---

* Read before the Harlem Medical Association of New York, March 2, 1904.

The patients, with one exception, had been married men, and each had had several children.

RESIDUAL URINE.

Four of the cases had complete retention, which, in one case, had persisted for five years. In only one case was the amount of residual urine small. All of the patients had been under medical treatment for a considerable time before operation.

DIAGNOSIS.

The diagnosis was made in every case from the history and from the rectal examination. In no case was a cystoscopic examination made. I believe, and in this belief I do not stand alone, that the cystoscope is not only an unnecessary, but often a dangerous instrument to use in the presence of marked prostatic enlargement. The information it gives us is often incomplete, and the harm it does is often great. It not rarely sets up an acute cystitis, the very thing we wish to avoid before operation. The less instrumentation to the urethra and bladder before the operation, the better for the patient and for the surgeon.

TECHNIC OF THE OPERATION.

With a few modifications, I have carried out the technic as I have seen it employed by Dr. Lilienthal at Mount Sinai Hospital. It was due to the gratifying results obtained by Dr. Lilienthal that I first attempted the operation. Much time and thought have been devoted to the problems of shortening the time of operation, lessening the shock and simplifying the after-treatment. Not one of the cases that form the basis of this paper came to the operating table in good condition, so the necessity for avoiding operative shock was evident. Moreover, two of the cases were old diabetics, and one of the patients was suffering from chronic sepsis. In none of the cases was it considered advisable to administer ether or chloroform. I doubted the practicability of doing the operation exclusively under laughing gas, as did others with whom I discussed the matter. Its repeated use has demonstrated not only its practicability, but also its desirability. Its use certainly lessens the dangers of the operation and at the same time widens its scope.

We have found that the time of operation can be reduced by cutting down on a distended bladder. If necessary, the bladder can be irrigated for several days before operation. Urotropin is given before operation. The patient is allowed to hold his urine for about twelve hours, and comes to operation with a distended bladder. With the patient in a moderate Trendelenburg position, a small incision is made above the symphysis pubis in the median line. The incision is deepened either between the two recti muscles or through the fibers of one rectus. Two silk-guide sutures are introduced into the wall of the bladder, and the viscus opened by a small incision in the median line. The interior of the bladder is rapidly explored by the finger, the size and relations of the prostate ascertained, and calculi that may be present removed. With a long-curved scissors, slipped along the index finger of the left hand as a guide, the mucous membrane over the prostate is incised. We make the incision over the most prominent portion of the prostate, and never make it more than half an inch long, just large enough to admit the tip of the index finger. The incision may be anterior, posterior or lateral to the urethral opening. If the prostate is deeply seated, it is pulled upward into the bladder by means of a special vulsellum forceps. If necessary, an assistant can press upward on the perineum, and in that way push the prostate further into the bladder, but we have not usually found this necessary. Up to this point there is little or no bleeding. The more rapidly the operation is now concluded, the less hemorrhage there will be. The entire prostate is shelled out of its capsule by the use of the index and middle fingers, first of one hand and then of the other. I have been accustomed to free the gland on the right side and posteriorly with the right hand. Then, by turning my back to the field of operation and introducing the left hand, the left side and anterior portions of the gland are freed. The *sine qua non* of this step of the operation is to work between the capsule of the gland and the gland proper; there is then no danger of wounding neighboring structures. As soon as the gland has been removed, a rapid examination is made with the finger to ascertain if any portion of the gland has been left behind. Without any irrigation of the bladder, a strip of plain sterile gauze is packed firmly against the raw surface left by the removal of the prostate.

AFTER-TREATMENT.

Equally important as the operation is the proper after-treatment. Fortunately, increasing experience has taught us many valuable lessons. It is essential to begin with continuous bladder drainage immediately after the operation. This drainage not only prevents infection of the perineal and prevesical regions, but also of the epididymis. At the same time it removes the necrotic shreds from the bladder and hastens the healing process. The packing that was introduced into the bladder at the time of operation is removed at the end of twenty-four hours, and thereafter no packings are employed. During the first two or three weeks the bladder should be irrigated twice daily. Either urotropin or some other urinary antiseptic should be continuously administered, and the urine should always be kept acid. The patient is allowed to sit up out of bed on the fourth or fifth day after operation, and a few days later is allowed to walk about his room. The healing of the suprapubic wound is hastened by keeping it well strapped with zinc oxid plaster. As the wound contracts a smaller tube is introduced into the bladder. As soon as no more shreds of necrotic tissue appear in the urine, the tube can be left out, and the wound may then be allowed to close. The time that the tube must be allowed to remain in the bladder varies with the size of the prostate that has been removed, and with the patient's power of recuperation. Two and a half to three weeks may be considered the usual time. After the tube has been removed, the bladder should still be washed out every day or two, either through a catheter passed per urethram, or through a small tube passed into the wound. The writer believes that in every case a sound ought to be passed three weeks after the operation, and thereafter regularly once a week for three or four weeks longer. A Mercier catheter may be used instead of a sound. The only case in this series that did not get a perfect result was one in which this sounding was omitted, and a stricture of the prostatic urethra resulted. This can and should be avoided in every case by passing a sound once a week after the third week.

CASE 1.—W. N., 82 years old, referred by Dr. Max Rosenthal. Three weeks before I saw him for the first time, he had been suddenly seized with retention of urine. Following this attack there was complete retention until the time of operation. High up in the rectum a moderately large prostate use of the catheter, and he would have soon been septic again. After careful consideration, and with the concurrence of Dr. Stark, it was decided to do a prostatectomy under laughing gas, through the suprapubic incision which had already been made. This was done eleven days after the preliminary operation. The former incision was enlarged a little by incising the fascia. The prostate was found firmly adherent to its capsule and required considerable force for its removal. A firm gauze packing was left in the bladder. The operation consumed eight minutes, and was accompanied by very little bleeding. The tumor consisted of two lateral lobes, each the size of a small plum, and about an inch of the urethra ran through the gland.

Three days after the second operation the patient developed a bronchopneumonia of moderate severity. He was delirious for several days, but his pulse remained good throughout. In ten days the temperature was again normal. Thereafter the convalescence was rapid and uninterrupted.

Oct. 30, 1903, the man returned to his home in excellent general condition, with a small suprapubic sinus. This healed very soon. Four months after operation the patient had gained 35 pounds; he was able to hold his water over four hours during the day and six hours at night, and there was absolutely no residual urine.

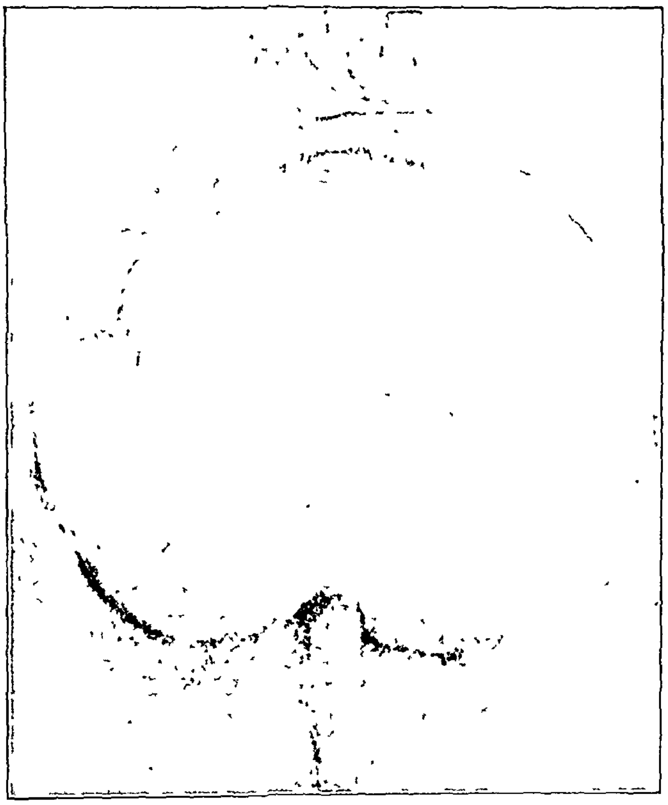

Fig. 2.—Case 4. Natural size. Urethra runs through anterior portion of prostate.

This is the most striking case of the series. No one, we think, will deny that a perineal operation under ether or chloroform would have promptly brought about the death of the patient.

Case 6.—A. M. R., 72 years old, was referred to me by Dr. Joseph Anderson. In 1897 he began to notice increased frequency of urination, both diurnal and nocturnal. This frequency of urination gradually increased until he was compelled to pass his water every hour and a half or two hours during the day, and five or six times during the night. Five days before his admission to the hospital the patient suddenly found that he was unable to pass any water. Repeated attempts to introduce a soft rubber catheter were unsuccessful. The writer saw the patient for the first time two days before operation, in consultation with Dr. Anderson. The bladder extended upward to a point about midway between the umbilicus and the free border of the ribs. On introducing a Mercier catheter it was obstructed at the prostate, and there was some bleeding. On introducing the finger into the rectum the prostate was readily felt enlarged to about the size of an *orange. After some difficulty the catheter entered the bladder,* and about three quarts of bloody urine were withdrawn. The patient's general condition was fair, but his sensorium was not quite clear, and he had a persistent singultus of three days' standing. The singultus and the retention of urine had appeared simultaneously. On the day following the catheterization the man entered the hospital. He had been unable to pass any water, and the singultus was still an annoying symptom. His sensorium, however, was more clear. The urine was found to contain a large amount of blood, but no evidences of nephritis were found.

Operation.—Two days after I had first seen him, Jan. 22, 1904, operation was performed under laughing gas. During the five days prior to operation urotropin had been freely administered. Without any previous catheterization a median suprapubic incision was made down to the distended bladder On palpating the interior of the bladder eight or nine calculi, several of them with irregular projections, were found and removed. With long curved scissors a small incision was made over the most prominent portion of the prostate. The entire gland was then shelled out in the usual manner, and a packing inserted into the bladder. No sutures were used. The patient lost less than two ounces of blood. The entire operation, from the time the knife was taken in hand until the packing was introduced into the bladder, took exactly six minutes. During part of this time, owing to the fact that the man *became excessively blue, no* laughing gas was given. Before he left the table he was fully awake. He assured me that he had felt nothing of the operation, and only complained of some discomfort in the rectum. He had been given a quarter of a grain of morphin hypodermically a half-hour before the operation. Singultus ceased on the fourth day and on the sixth day the man was allowed to leave his bed. Two days later he was allowed to walk about his room.

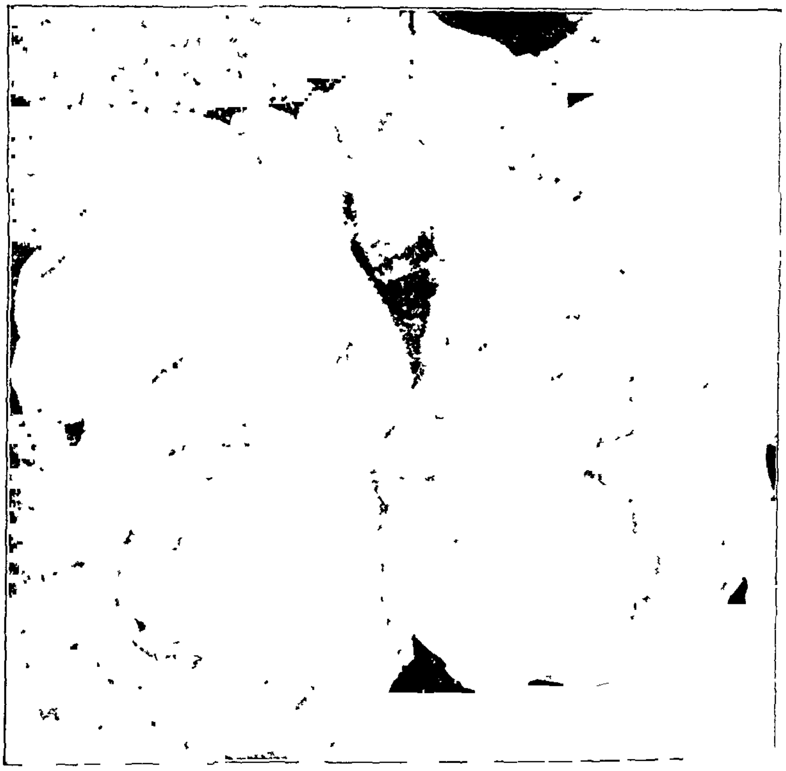

Fig. 3.—Case 6. Natural size. Two enormous lateral lobes

February 23 the sinus was cauterized with the Paquelin cautery. On the following day the man began to urinate voluntarily, and thereafter very little urine escaped through the wound, which was soon completely healed. The very much distended and weakened bladder probably delayed the convalescence somewhat in this case.

CONCLUSIONS.

The foregoing cases we believe justify the following conclusions:

1. Suprapubic prostatectomy can be rapidly and safely performed under laughing gas.

2. Any patient who can stand laughing gas for ten or twelve minutes can have the operation performed.

3. Old age, diabetes and cystitis are no contraindications.

4. All of the contraindications usually mentioned are contraindications not for the operation but for the administration of ether or chloroform.

The value of laughing gas and of rapid work in these old prostatic cases can not be overestimated. These two factors are, we believe, the keystone to success in suprapubic prostatectomy. Few, indeed, are the patients, even though 80 years of age, or suffering from diabetes or sepsis, that can not be entirely cured. So we are now enabled to offer these poor old men an almost certain promise *of a complete cure by an operation* that can be done without ether or chloroform, that rarely takes more than twelve minutes to perform, and last, but not least, an operation that has a *mortality of but 4 per cent.*

1001 Madison Avenue.

Note.—Since writing the above paper I have performed prostatectomy under nitrous oxid on a seventh case. Mr. M., 75 years old, was suddenly unable to pass any urine on April 4, 1904. Attempts at catheterization were followed by considerable bleeding. April 7 I was asked to see the man by Dr. Dinkelspiel. The bladder was distended by urine and blood clots and could not be thoroughly emptied. Accordingly I performed suprapubic cystostomy under gas and removed a handful of clots. Eight days later, through the same incision, I removed the prostate under gas in less than two minutes. The prostate was as large as a lemon and was traversed by the prostatic urethra. The man is making a satisfactory recovery.

THE MEDICAL PROFESSION

IN THE PUBLIC AND PRIVATE LIFE OF AMERICA.*

CHARLES A. L. REED, A.M., M.D.
CINCINNATI.

The delivery of an address before the Army Medical School, while a pleasant distinction for which I am grateful to the surgeon general, involves, nevertheless, a responsibility that I approach with conscious diffidence. This feeling of trepidation arises, in part at least, from the fact that, as a professional man engaged however, in civil practice, I find myself surrounded by new conditions that are provocative of new thoughts and suggestive of new problems. Thus, for instance, there comes quite naturally to my mind the thought that the medical profession, wherever taught, avowed or practiced, presents the phenomena of a certain unity, a certain solidarity; but that, as exemplified, respectively, in public and private, military and civil practice, it presents important variations, and finally, that the causes of the variations and the reciprocal relations of the variants must be matters of interesting if not important consideration. This same train of thought, probably in obedience to the law governing the association of ideas, leads to the conjecture that what may be true of one profession may be true, to an important degree, of other professions represented in the national services.

A QUESTION OF DEFINITIONS.

In approaching this subject it is well, however, to remember, among other things, that this is a day of social evolution; that the changes incident to which come with almost revolutionary rapidity; that these changes are characterized, conspicuously, by the segregation of the people into classes or groups, more or less distinct; that many of these classes, or groups, without reference to being learned or otherwise, designate themselves as professions; and that this process has gained popular recognition and official sanction until, as a consequence, it is no longer possible for us to restrict the use of the word "profession" to the original learned callings of law, medicine and theology. On the contrary, we are forced to accept the conventional definition that a profession is "specifically a vocation in which a professed knowledge of some department of science or learning is used by its personal application to affairs of others, either in advising, guiding or teaching them, or in serving their interest or welfare by the practice of an art founded on it."

If, however, it is necessary for us to get new and accurate bearings about the word "profession," it is even more important that we understand what is implied by the "public life" or the "public services," or, more to our own present purposes, the "national services." In general terms, "public services" represent the more or less specific or classified activities demanded by the community without reference to territorial limitations, and paid for either in money, honor or abuse. These services may be restricted to the town, county, state or nation, to the last of which, as represented in the coordinate branches, legislative, judicial and executive of the government, these observations shall be restricted.

If, then, as already indicated, professions have become multiplied, and if we are to study them as represented in the national services, it may be well, by way of preliminary survey, to glance at the number of callings that come within the range of our definitions, representatives of which are to be found enrolled on the official register. I confess search is a little difficult and the result is a little surprising. Of course, law, medicine and theology, the parent professions, like the poor, are always with us, and are liable to remain so long as men violate the laws, national and statutory, and thus destroy their present happiness and jeopardize their prospects of eternal bliss. But, in addition, not to pause with the useful and recognized classes of dentists, veterinarians and nurses, there are physiologists, pathologists, paleantologists and pomologists; educators, engravers, entomologists and engineers, civil and uncivil; botanists, biologists and bibliographers; chemists, climatologists and cartographers; architects, accountants and one lonesome solitary agrostologist. Many of these, like the specialty of grasses, are represented by but one, or at most a very few individuals, a circumstance which makes a detailed consideration of each quite impracticable in this connection. We may, however, with propriety, discuss the original learned professions as the most conspicuous examples, and study their relations to the different branches of the government. Thus, to begin with the law-making power, we find, as nearly as can be ascertained from the Congressional Directory[1] that, of the 475 members of both branches of the Congress, the politicians form a solitary and innocent group of but 7 members, while there are 322 lawyers, 2 physicians, and not a single preacher among them. It would seem, therefore, either that it takes a tremendous lot of law to hold seven politicians straight, or else that the electorate, seeing how everything is hopelessly given over to the law, has—quite inconsiderately, I protest—sent its representatives to Washington with small care for their bodies and none for their souls.

---

* An address delivered at the annual commencement of the Army Medical School, Washington, D. C., April 5, 1904.

[1] The biographical sketches in the *Congressional Directory* indicate the following composition of the respective branches of the Congress: *Senate*—Lawyers, 53; physicians, 2; merchants, 9; farmers, 1; bankers, 2; politicians, 1; miscellaneous, 22. *House*—Lawyers, 259; merchants, 9; farmers, 11; editors, 10; bankers, 9; politicians, 6; teachers, 5; miscellaneous, 76.

The personnel of the judicial branch is, naturally enough, made up exclusively of representatives of the legal profession. The various services of the executive departments, however, represent practically every variety of professional employment. There are lawyers, physicians and surgeons, clergymen, dentists, engineers and others, the statistics concerning whom I have ascertained, on inquiry, have not yet been compiled. These professional men, whatever their number, are, however, the representatives in public life of professions which, according to the last census, numbered, respectively, in the United States, 114,703 lawyers, 132,225 physicians and surgeons 111,942 clergymen, 29,683 dentists, 57,975 engineers, of whom 43,538 were classified as "civil" and 14,440 as "mechanical and electrical," making a total of 446,528 persons represented in the five professions.

INTERESTS INVOLVED.

These aggregates are presented to show the magnitude of the interests that are, to an important degree, influenced by the representatives of the respective professions in the various services. This influence is very much more real and far-reaching than may be inferred without a careful consideration of the subject. In the first place, professional service rendered the government is the most conspicuous service of its kind that can be rendered to society; if it is efficient the science which it represents is advanced in public esteem; if it is inefficient the entire profession for which it stands is to that extent discredited. It follows, therefore, that professional service to the government is fraught with responsibility, not only for the trust immediately reposed on it, but for the even greater, although indirect, trust represented in the welfare of the profession thus brought to the bar of public opinion. I venture the assertion that it is this consideration, second only to the motives of patriotism and altruism, that prompts the professions—and I now speak more particularly of the medical profession—to approve of the severity of examinations which raises, at least, a presumption of efficiency on the part of those finally selected for the services. Or, to take another example, if a given profession were to accept from the government a lower compensation than that paid to other professions invested with similar responsibilities, the precedent would tend, relatively, to cheapen that profession in private life. The same principle holds true when one profession is denied rank, position or social prerogatives accorded to other professions of similar educational and social antecedents. It follows, therefore, that the professions in private life have a direct personal interest—an interest more practical if not more real than that prompted even by *l'esprit du corps*—in all that affects efficiency of their confrères in public life.

INFLUENCES TO BE CONSIDERED.

Among the influences thus to be taken into account, none, possibly, is of more importance than that of tenure. This, of course, varies in the different branches of the government, elective offices being held for specific periods, while appointive ones are of variable tenure, an increasing tendency being manifested to increase the number of life holdings. The merits of the two systems have long been and still remain subjects of inquiry. There is no doubt that the superiority of the national judiciary, appointed for life, over the state judiciary, elected for definite periods, has been the one influence most largely responsible for the present strong sentiment in favor of life tenure. The excellent results that have been realized through the workings of the Civil Service Commission, such, for instance, as the extension of life tenure to the classified offices, is another salutary influence that accounts, in large measure, for the present high efficiency in our executive services. The fact that a public servant, especially one that is invested with either judicial or executive duties assured of his career, is placed beyond both the whims of the boss and the caprice of the populace, raises a presumption in favor of the faithfulness and disinterestedness of his labors. While this is true, and while I have not the least disposition to question the value of reforms that have taken place and that are still in progress, relative to tenure, I can not ignore certain facts and tendencies which may be said to comprise the other side of the question. Thus life tenure, with promotion based entirely on time service, takes away the stimulus of necessity, and has a tendency to render the discharge of duty more or less perfunctory. There are men, and women, too, for that matter, to whom no greater misfortune can befall than that of an assured future. With them hope becomes circumscribed by regulations, and ambition becomes paralyzed by the certainty of conditions. This tendency, if it were to become dominant, as I am gratified to believe that it is not, would, in the course of logical development, make society the victim of the joint evils of bureaucracy and parasitism. Another tendency, however—one manifested proportionately to the completeness of the individual's devotion to his public duties—is his increasing incapacity to meet the requirements of a private career. It may be asserted that with ten or fifteen years' experience in the medical service of either the Army or the Navy, the individual, whatever his technical qualifications, if he attempts to return to private practice, will find himself seriously handicapped by unfamiliarity with those social and quasi-political influences that largely determine success. I am advised that the same is true to an extent of lawyers, who have learned to rely on a paymaster rather than a clientele. This represents no loss, however, to the energy of the community if the change in the individual amounts simply in his completer adjustment to the circumstances and requirements of a public career. If, however, they imply loss of interest in prescribed duties and loss of hope in private life and result in attempts to seek refuge in vicious indulgences, the loss is a double one. The greatest loss that a professional man can sustain is the loss of enthusiasm in his profession, while the greatest loss that a community can sustain is the loss of the productive energy of its members. Fortunately, however, such losses as these, I am persuaded, are sustained through the public services only in individual instances. And I have mentioned them here only to emphasize the existence of tendencies on which they are based, tendencies that, in a certain sense, have logical beginnings and equally logical endings.

REMEDIAL MEASURES.

Correct, however, as may be a diagnosis, it is of small value unless it leads to the adoption of curative measures for the present and preventive measures for the future. When this phase of the question is taken up one is at once brought face to face with the personal element in the equation, an element that can never be ignored. Nothing can come out of a man that is not in him, be it good or evil, and one or the other will come out of him, according as it preponderates in him. Yet no man is wholly bad, and there is none who is not responsible to an important degree to the stimuli of ambition and hope. Ambition makes him amenable to the *esprit du corps* of his service, which, if high, lifts him to the higher levels of endeavor, but which, if low, will only encourage the development of besetting tendencies.

In addition to this it would seem important that those in authority should give to their subordinates the fullest opportunity for the development of individualism, consistent with efficiently ordered discipline; for the strength of any service can best be promoted by promoting the strength of its individual units. Not only is it important to promote individualism, as shown by power of initiative, always, of course, under necessary restriction, but it is almost equally important to concede opportunities for individual reputation. There are few men, I fancy, in the services who do not possess, in some degree, that weakness known as the love of approbation, and if there is such an one he ought to be expelled as an unsafe member of the corps. It is, however, important to discriminate between the intelligent appreciation of those whose approval is worth having and the ephemeral praise of the multitudes who, unthinkingly applaud to-day and cruelly forget to-morrow. That form of approval, however, which finds expression in promotion for cause, is of the most wholesome sort, while the reverse rule—that of degradation or dismissal, equally for cause—can not but be a corrective agency of great value to those who are not appreciative of good fortune.

POST-GRADUATE INSTRUCTION.

Important as are these influences, they do not, however, have a direct bearing on the fact that, in spite of increasing experience, there is a tendency to grow unfamiliar, if not actually to forget, much that ought to be kept well in mind. This fact has been recognized by both the Army and Navy in the establishment of special service schools. These institutions—such as the Artillery School at Fort Monroe, the Engineer School of Application at Washington, the School of Submarine Defense at Fort Totten, the School of Application for Cavalry and Field Artillery at Fort Riley, the General Service and Staff College at Fort Leavenworth, and the War College at Washington—are intended for advanced technical instruction for the strictly military profession, while the Army Medical School at Washington is designed to give similarly advanced and special instruction for members of the Medical Corps. Similar institutions exist in the Navy. So far as these institutions relate to medicine, they tend to confirm the fact, already extensively recognized, that military medicine is a distinct specialty of the healing art. This is manifested in the curriculum presented by General Orders, which embraces the topics of (*a*) the duties of medical officers in war and peace; (*b*) military surgery, the care of wounded in time of war and hospital administration; (*c*) military hygiene; (*d*) military medicine; (*e*) microscopy, sanitary and clinical, pathologic histology, bacteriology and urinology; (*f*) hospital corps drill and first aid to the wounded.

SCOPE, POSSIBILITIES AND NECESSITIES OF THE ARMY MEDICAL SCHOOL.

A mere glance at the foregoing subjects shows that the essential object of the Army Medical School is to adapt medical science to the requirements of military life. The necessity for such a course of study becomes apparent when it is remembered that the curricula prescribed in the medical schools of the country do not, and in the nature of things ought not, to embrace the highly specialized subjects that relate, almost exclusively, to military practice. Such studies are, however, essential for the regular Medical Corps. But when it is remembered that, in times of war, the regular Medical Corps, numerically considered, is totally inadequate to meet the requirements of the service, and that, at such trying moments, it is necessary to rely on the medical officers of the National Guard and on volunteer and contract surgeons, the scope and possibilities of the Army Medical School, for the proper education of this auxiliary medical service, becomes apparent. Its usefulness would be still further increased if the bill for the reorganization of the Army Medical Service, creating a reserve medical corps, were to become a law. To meet these requirements—to meet even the existing requirements, however—it is simply essential that the Medical Department shall be provided with a large central hospital, strictly up to date, to serve as a clinical school for medical officers and as a training school, alike for the Hospital Corps and the Nursing Corps. A failure by the Congress to provide this means of instruction is simply a blow at the medical service, the efficiency of which is essential to the efficiency of the Army itself. Such a failure, when viewed in the light of the expenditure of millions on millions of the public money for the construction of unnecessary postoffices in unheard-of towns, and for the alleged improvement of tideless streams, is a species of culpability for which each participant ought to be held to strict account by his constituents.

MEANS OF RECRUITING PROFESSIONAL RANKS IN THE NATIONAL SERVICES.

The professions as represented in the national services are variously recruited. Thus, in the legislative branch, they are elected; in the judicial they are appointed, without examination, while in the executive department they are appointed, some with, some without, examination. Whatever may be the method of selection, the new incumbents are drawn directly from the ranks of their profession in private life. I wish to emphasize the word "directly," for it is important, as implying that men thus selected pass, for the most part without intermediate training or experience, from private into public practice. Such a transition, whether in law or medicine, is too sudden to enable the individual properly to adjust himself to the requirements of his new station. It thus becomes apparent that, in every branch of governmental employment of a professional character, some provision, whether by a system of promotions or by the organization of reserve corps, ought to be devised as a safeguard to the efficiency of the service. This is especially true of the Medical Corps, which, at such times as our last two wars, was forced to rely on men who, without reference to their scientific attainments, had never been taught to appreciate nor drilled to meet the peculiar requirements of the service. But, without reference to war emergencies, it would be a vast improvement over the present contract system to create a reserve corps, consisting of men, appointed on examinations, who, although not in the service, would be eligible to the Army Medical School, and who, by other means, would be giving serious study to the duties of the army surgeon.

THE QUESTION OF STATUS.

The status of such a reserve corps, whether in the Army, the Navy, or the Public Health and Marine-Hospital Service, or whether relating to professions other than the medical, should be made definite and need not, in the least, interfere with the status of any corresponding services, as at present organized. As I have already stated, the present status, particularly in the three services just mentioned, is rendered definite by regulations. These regulations, to the informed and impartial mind, are, in many instances, neither wise nor just. They, however, who have accepted service under them must expect to abide by their provisions. I do not mean to imply by this that men, affected by unjust rules, ought not to attempt, by prescribed and lawful means, to remedy the evil. It can readily be understood, however, that if everybody connected with the public services were to attempt, by one means or another, to change existing conditions, the executive would be besieged, the Congress would be overwhelmed, and endless confusion would result. It was doubtless conditions leading to precisely such a state of affairs that prompted the general order, by which officers and employes of the government were forbidden, under pain of dismissal, to attempt, directly or indirectly, personally or through associations, to promote their own interests.

GENERAL ORDERS NO. 18.

Headquarters of the Army,
Adjutant General's Office,
Washington, Feb. 19, 1902.

The following has been received from the War Department:

War Department, Washington, Feb. 19, 1902.

The following Executive Order has been received from the White House and is published for the information and guidance of all concerned:

EXECUTIVE ORDER.

All officers and employes of the United States of every description serving in or under any of the Executive Departments and whether so serving in or out of Washington, are hereby forbidden, either directly or indirectly, individually or through associations, to solicit an increase of pay or to influence or attempt to influence in their own interest any other legislation whatever, either before Congress or its committees, or in any way save through the heads of departments in or under which they serve, on penalty of dismissal from the government service. Theodore Roosevelt.

White House, Jan. 31, 1902.

At the same time special attention of the officers of the Army is called to the following existing provision of the Army Regulations:

. . . . "Efforts to influence legislation affecting the Army, or to procure personal favor or consideration, should never be made except through regular military channels; the adoption of any other method by any officer or enlisted man, will be noted in the military record of those concerned." (Par. 5, A. R.)

Elihu Root, Secretary of War.

By Command of Lieutenant-General Miles:
H. C. Corbin, Adjutant General, Major General U. S. Army.

DUTIES OF THE PROFESSION IN PRIVATE LIFE TO THEIR PUBLIC CONFRERES.

While the position thus assumed is, unquestionably, justifiable from a governmental or disciplinary standpoint, there remains, however, another and very serious side to the question. It must be remembered, as I have already intimated, that the professions in the public services are, primarily and essentially, the representatives of the corresponding professions in private life; that the status of the professions in the public services, relative to other professions, persons and classes, will and must be recognized as a criterion of the relative status of the corresponding professions in private life; and that, consequently, the professions in private life, jealous alike of their positions and their prerogatives, must see to it that neither are compromised through precedents established either for or by their public representatives. Recognizing, as has been shown, that the hands of their public confrères are tied by executive restriction, it becomes the duty of the respective professions, in their organized capacity, to take the initiative in correcting any influences which, in a reflex way, may act detrimentally on their own welfare, whether in public or private capacity. When such action can be coupled with unquestionable considerations for the public good, the obligation becomes doubly imperative. But, aside from the altruistic motive, and as a complete justification for intervention, it is to be remembered—and in effect I again repeat myself—that this is an age characterized by the rapid evolution of social groups and classes; that these groups and classes are already jostling each other for place; and that, consequently, that group or class, or, more specifically, that profession must be vigilant and courageous that would guard its prerogatives and conserve its status in a democracy presumably founded on the principle of equality.

Such intervention ought to be undertaken only after careful consideration of all the interests involved. Care should be taken to avoid the tendency to consider the view point of a given profession as the only view point in the case. Representations should be made, whether to the legislative or the executive departments, always with profound respect for the intention of those in authority to conserve all the interests placed in their hands, but with the feeling, the assurance, that the view point of the legislator or of the executive may not be the only view point in the case. Thus, to illustrate, it would seem that a given profession would be justified in making respectful representations to the heads of executive departments when its representatives in the services are placed in positions of responsibility, without authority to control or determine results; or, when final judgment is passed on the technical knowledge it represents by those who are ignorant of the subject; or when it is ignored in the composition of commissions of mixed membership, dealing in a large way with the practical application of the art and sciences for which it stands; or when it is excluded from consultative bodies on which its skill and position would, naturally, entitle it to representation; or when its technical qualifications are permitted to act as a *bar sinister* to its preferment in any capacity to which its general attainments entitle it to consideration.

In the legislative field, however, the duty of the professions to themselves and to the public are even more distinct. To begin with, each profession owes it to itself to be adequately represented in all legislative bodies, state and national. No profession can complain if it is the victim of inimical legislation, passed during absence from these posts of duty. On the other hand, the professions owe to themselves and to the people certain self-denials in the direction of legislative work. Thus, speaking now more particularly for the medical profession, laws relating to its status and efficiency in the public services, laws regulating the study and practice of medicine, laws relating to the public health, touching such questions as the sanitary reclamation of public lands, the protection of streams from pollution, the protection of interstate commerce from disease-producing agencies. quarantine, the prevention and management of epidemics, the manufacture of drugs, the purity of food and water supplies, need the attention of the medical profession in legislative bodies.

I have discussed these questions in this presence today, because this is conspicuously an institution identified with and representing the largest public interest of the medical profession. You, gentlemen, go forth today as specialists in military medicine. Your careers in the medical schools, where you received your doctorate, your success in passing the rigorous entrance examinations in the Army Medical Service, the splendid records you have made as special students in this institution, commend you to the confidence of the secretary and to the esteem of your profession. The start you have thus made is accepted as a prophecy of achievements to follow actual labor in the field of your choice. Be assiduous; interest yourselves in original investigations; study the highest efficiency of your service, and in return I am authorized by the American Medical Association to vouchsafe to you the protecting influence of your great profession, whether duty shall place you in the favored spots of our mainland or shall send you to the far-away islands of the sea.

THE ARMY MEDICAL DEPARTMENT.

II.

A HISTORICAL SKETCH.

(Continued from page 1217.)

The Civil War was the first in which large armies made their appearance on American soil, and in these great army corps of volunteers many of the glorious traditions and hide-bound prejudices of the old Army disappeared along with its regiments and batteries. Yet it was none the less the leaven hid in three measures of meal, which leavened the whole lump, and this is true not less of the Medical Department than of the line.

On Jan. 1, 1861, the Army numbered 16,400 and the medical officers 115, or .7 per cent. of the whole—a considerably greater proportion, by the way, than exists to-day. Although by far the largest of the staff corps, it had the smallest proportion in the higher grades, and this also is still the case, with the single exception of the Signal Corps, the junior of all, whose handicap is perhaps a matter of inheritance, as its originator, Myer, was a medical officer.

The medical history of the Civil War marks an epoch in military sanitary organization even greater than was made in the art of war by Sheridan's use of cavalry or the hasty entrenchments of Lee. It is a glorious chapter of American history, but the full story of the ability and devotion of the surgeons of the Civil War, regular and volunteer, must be sought, not in the limits of an article, but by those who have industry and good eyesight, in the ponderous volumes of microscopic print which make up the "Medical and Surgical History of the Rebellion."

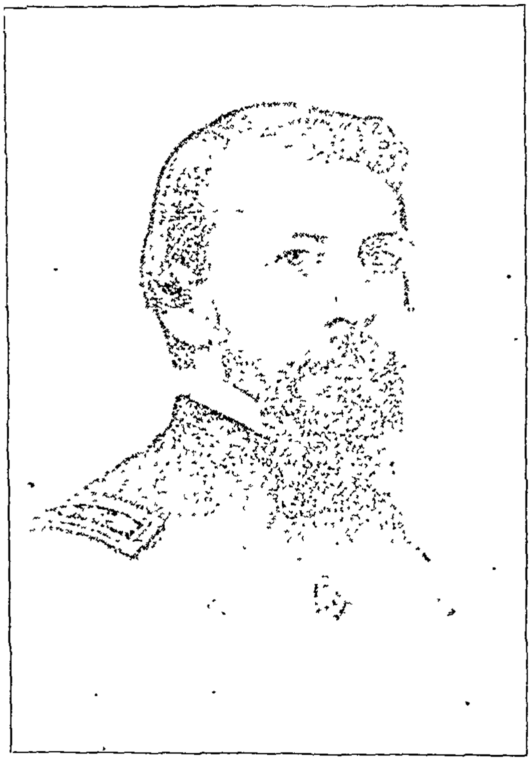
The idea of medical organizations in the field, drilled and trained to gather up the wounded from the battlefield, transport and care for them, developed by Larrey and Percy in the Napoleonic wars, had perished with the armies of the First Empire under the retroactive prejudices of the old monarchies, and the military taboo of even republican America forbade a physician to exercise the sacred function of "command" over trained enlisted assistants of his own department or even to have a permanent and unquestioned jurisdiction over the mules and drivers of the medical ambulances. He controlled in battle his own two hands, and these only, unless the colonel saw fit to give him the uncertain and doubtful assistance of the regimental band. The following letter taken from the files of the Surgeon-General's Office permits a glimpse of the tragedy behind the scenes:

Surgeon General's Office, Sept. 7, 1862.

Honorable Edwin M. Stanton, Secretary of War.

Sir:—I have the honor to ask your attention to the frightful state of disorder existing in the arrangement for removing the wounded from the field of battle. The scarcity of *ambulances*, the want of organization, the drunkenness and incompetency of the drivers, the total absence of ambulance attendants are now working their legitimate results, results which I feel I have no right to keep from the knowledge of the department. The whole system should be under the charge of the Medical Department. An ambulance corps should be organized and set in instant operation. I have already laid before you a plan for such an organization, which I think covers the whole ground, but which I am sorry to find does not meet with the approval of the general-in-chief. I am not wedded to it. I only ask that *some* system may be adopted by which the removal of the sick from the field of battle may be speedily accomplished and the suffering to which they are now subjected be in future as far as possible avoided.

Up to this date six hundred wounded still remain on the battlefield in consequence of an insufficiency of ambulances and the want of a proper system for regulating their removal in the Army of Virginia. Many have died of starvation, many more will die in consequence of exhaustion, and all have endured torments which might have been avoided.



Surgeon Jonathan Letterman.
Medical Director Army of the Potomac 1862-1864.

I ask, sir, that you will give me your aid in this matter, that you will interpose to prevent a recurrence of such consequences as have followed the recent battle, consequences which will inevitably ensue on the next important engagement if nothing is done to obviate them. I am, sir, very respectfully,

Your obedient servant,

William A. Hammond, Surgeon General.

Yet even this picture of the 600 men who had lain ten days on the battlefield of Second Bull Run could not bring the commanding general to lift the taboo and approve of enlisting men for the Medical Department But while the Surgeon General was vainly struggling with the prejudices of General Halleck, light had broken in another quarter. July 1, 1862, Surgeon Jonathan Letterman reported to General McClellan to be medical director of the Army of the Potomac. He was only 38 years old, having entered the service in 1849, and had just received his promotion to major. The Army of the Potomac was at this time crowded with sick and with the wounded of the seven days' fight, and in the retreat to Harrison's Landing most of the medical equipment and supplies had been lost or expended. In the course of a month he brought order out of this chaos, and at the same time drew up a plan for an ambulance corps—simple, far-reaching and effective—which General McClellan was quick to adopt. The personnel for this corps was obtained by transfers of officers and men from the line, and they, as well as the ambulances and other transportation, were placed entirely in the hands of the medical directors of the several army corps. A distinctive uniform and a simple drill were prescribed. This organization was announced in orders apparently without reference to Washington on August 2, and was soon followed by a scheme for regimental medical service and the establishment of division field hospitals in October. These taken together made a complete workable system, which at once made a new epoch in medical organization, and placed the Army of the Potomac far ahead of any military establishment in the world in this respect.

Meanwhile the system had its first trial at Antietam September 7, where the wounded of the Army Corps from the Army of the Potomac were promptly removed from the field and cared for, being in marked contrast with the experience of the wounded of the other wing made up of troops from Pope's army. In the bloody battle of Fredericksburg, where, in addition to the great number of wounded, was added the confusion of a defeat, the ambulance companies nevertheless did their work with smoothness and dispatch, and the wounded were transported without confusion or delay to the division field hospitals. As reported by Surgeon Charles O'Leary, medical director of the Sixth Corps, it "afforded the most pleasing contrast to what we had hitherto seen during the war."

This medical organization soon spread to the other armies of the United States, and was formally adopted by Congress in the spring of 1864. It was not copied from European models, but, on the contrary, has been, in its essential features, adopted by all civilized nations, and it is probable that the name and fame of Jonathan Letterman are better known to-day to the military surgeons of Europe than in his own country. Nor during his lifetime did this great and beneficent genius receive any promotion or any reward other than the commendation of his general and the admiration of his professional comrades. This splendid constructive work was done, and the vast responsibilities of chief medical officer of a great army were met and surmounted by a man who was given only the rank and pay of a major. When the Surgeon General proposed that the medical directors of the armies under McClellan and Halleck be given the temporary rank of colonel, which was enjoyed by other staff officers, the War Department returned the ungracious and fatuous reply: "Refused unless it can be shown that the skill and efficiency of surgeons are increased by an increase of rank and pay." This rank was afterward given to the medical directors of armies in the field by the Act of Feb. 23, 1865. It is not surprising that Letterman, broken in health by his great labors and disgusted at the blind ingratitude of those in authority, resigned from the service in December, 1864, and died in San Francisco some years later.

The Medical Department during the Civil War disbursed over $47,000,000, and cared for 1,057,423 sick in its general hospitals alone, without counting those that passed through the field and regimental hospitals. Of the medical staff, 115 were shot in battle, of whom 42 died, and 285 died of disease.

This great struggle has left behind it as monuments of the labors of the medical profession, the Army Medical Museum and the great national institution known as the library of the Surgeon-General's Office. The record of their professional work is given in the "Medical and Surgical History of the Rebellion," which, in spite of the advances in professional knowledge since that time, remains an inexhaustible mine of statistical information, while the reports of medical directors in the appendix are of permanent value and interest to all who are interested in the great and ever-recurrent problems of medico-military administration.

(To be continued.)

Clinical Reports.

GENERAL SYSTEMIC INFECTION BY THE DIPLOCOCCUS OF NEISSER COMPLICATING CHRONIC GONORRHEA.

THOMAS J. STRONG, M.D.
U. S. Army General Hospital of the Presidio.
SAN FRANCISCO.

A case is herewith presented of gonorrheal pyemia, which I believe is the first authenticated one in the history of this hospital. This case presents a peculiar feature, interesting and instructive from a clinical standpoint, in that the microscopic examination of smears, and the cultures, show a pure gonococcus infection.

Patient.—D. G. W., private, Company K, Eleventh Infantry, was admitted to this hospital, Jan. 15, 1904, complaining of pain and swelling in muscles of right side of neck, right arm, right leg, and left arm. No other symptoms were complained of, except slight temperature and coated tongue.

Previous History.—Had pertussis when a boy; had typhoid fever six years ago, which was of three months' duration and quite severe; had mumps five years ago, no complications; had measles at Fort McPherson, Ga., three years ago, and malaria in Philippines in 1902. From these diseases he fully recovered and was in good health when he enlisted.

Present Trouble.—In June, 1900, patient had a severe attack of gonorrhea, complicated by an epididymitis of the right side, which he says was cured after about two months' treatment, and also the discharge from urethra ceased. While en route from Manila, P. I., to San Francisco, the patient had intercourse at Nagasaki, Japan, but emphatically denies that he had any symptoms of gonorrhea, nor any inconvenience whatever until about two days before arrival at San Francisco, when he noticed pain and swelling of the muscles above-mentioned, namely: of the right sternomastoid, the right shoulder, the right thigh posteriorly, and left upper forearm. These localities were tender, red and swollen, but even at this time no discharge had been noticed from the urethra until the day he was admitted to this hospital.

Examination.—The day after admittance, Jan. 16, 1904, a circumscribed abscess was found, involving the extensor carpi ulnaris and extensor minimi digiti muscles at the upper part of the forearm, about one and one-half inches below the inner condyle of the humerus. Another abscess at the lower anterior border of the right sternomastoid muscle just underneath the latter. The right biceps was hard and indurated about its middle, and the flexor muscles of the thigh were in like condition. Some tenderness at the right shoulder just at the anterior border of the deltoid muscle.

Treatment.—These inflamed localities were carefully cleaned externally and wet dressings of bichlorid of mercury (1-2,000 solution) applied, and urethra was irrigated twice daily with protargol (solution 1 per cent.). January 21 the abscess of the left forearm was opened and about 45 c.c. of pus was evacuated. Two smears of this pus were taken for microscopic examination. The cavity was flushed with hot bichlorid solution, packed with iodoform gauze, and dressed antiseptically. The abscess at the border of the right sternomastoid muscle was opened at this time also, carefully cleaned out and packed with gauze.

Course.—On January 22 the swelling at the junction of the right deltoid and pectoralis major muscles had developed to such an extent that fluctuation was detected and it was promptly opened. A culture of the pus was made on blood serum, and the cavity flushed out and packed with iodoform gauze. As no more abscesses were in evidence, the patient was placed on light nutritious diet, bowels kept open by salines, and whiskey given every four hours. The pus from the last abscess, that of the shoulder, was also obtained on a cover glass and prepared for staining for microscopic examination. It showed innumerable gonococci and nothing else, the cocci being more plainly seen in this specimen than any previous ones. A blood count showed a marked leucocytosis: 66,000.

On January 24 the blood serum culture showed a typical growth of the gonococcus in yellowish isolated spots on the culture media.

The patient at this date, January 30, is improving daily, and gaining in weight. No further complications have been noticed, and by his own statements he feels better than he has for two years.

Comments.—It is highly probable that this case was one of pyemia of some duration, more or less latent until a new stimulus was awakened by the second infection acquired in Japan, and not fully developing until two or three weeks afterward.

Thanks are due Lieut. Chas. F. Craig, assistant surgeon, U. S. A., pathologist at this hospital, for the excellent demonstrations, microscopically and culturally, of the specimens of this case, and due credit is also given to Lieut. J. C. Gregory, assistant surgeon, U. S. A., who transferred the case to the writer with the suggestion that the abscesses might be due to gonorrhea, as the patient had a discharge from urethra at the time he was transferred from a medical to the genito-urinary ward..

Patients having gonorrhea, suddenly developing abscesses of the muscles, etc., or of internal organs with no other appreciable cause, may be suspected, with reason, of having a gonorrheal pyemia, but the diagnosis should be guarded until the condition is assured by a bacteriologic examination.

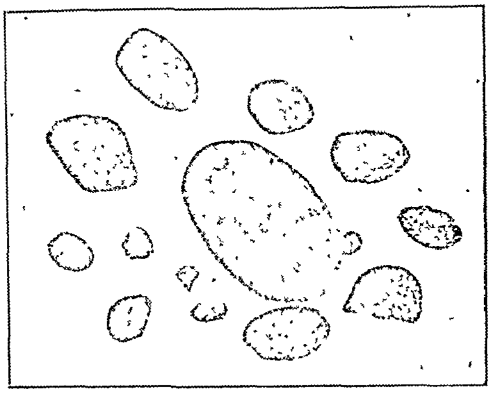
MULTIPLE CALCULI IN THE MALE URETHRA CAUSING OCCLUSION.

RAYMOND F. METCALFE, M.D.
First Lieutenant and Assistant Surgeon, U. S Army
MANILA, P. I.

History.—G. I., a Filipino male, aged 25 years, gave the following history: Eight years ago, while urinating, he was taken with a sudden, severe lancinating pain in the penis and along the entire course of the urethra. From that time he states that he was never free from pain, which was exaggerated by urination and at times an acute exacerbation would occur which would confine him to his bed. His urine was tinged with blood, and he passed it only twice in the twenty-four hours on account of the severe pain which it caused. One of these acute attacks occurred Dec. 2, 1903.

Examination.—December 5, I was called to see the patient by Contract-Surgeon Jones. The temperature was 102 F., pulse 110. The scrotum was greatly enlarged, dark and congested, the skin tense and shiny, with two small areas on the anterior surface showing signs of necrosis; the perineum was bulging. Midway between the scrotum and the anus, a little to the left of the median line, was the mouth of a fistula which was discharging urine mixed with pus. The patient was in great agony and could not stand the slightest pressure on the scrotum. He was removed to the hospital at once and anesthetized to allow thorough examination, and operation, if necessary, the appearance of the tissues suggesting extravasation of urine. The patient had been unable to pass urine except a few drops at a time, for several days. A silver catheter was tried and three inches from the meatus it grated against a substance like stone and would go no further. A filiform bougie was tried with the same result. A probe inserted in the fistula grated against the same object.

Operation.—With the patient in the lithotomy position, I made a perineal incision two inches long in the median line. As a guide could not be passed and as the tissues were edemic, the urethra was found with some difficulty. A hard mass could be distinctly felt to one side of the membranous urethra; an incision was made over this mass and an oval concretion, one and three-quarters inches by one inch and weighing twelve and one-half grams was removed. It was lodged in a sacculated pouch formed by a dilatation of the urethra, and along the course of the urethra and posterior to the above were five other similar but smaller concretions with a combined weight of nineteen and one-half grams. Each stone was surrounded by a considerable amount of pus.



The stones, one-half actual size.

The wound was flushed and a catheter introduced into the bladder and about eight ounces of strong smelling urine removed. No stones could be detected in the bladder, so a catheter was introduced and left *in situ*, a siphon tube attached, and incision packed with gauze. Recovery was uneventful.

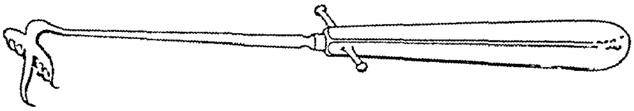
First Reserve Hospital.

New Instrument.

AN IMPROVED RETRACTOR FOR THE SO-CALLED RADICAL OPERATION ON THE MIDDLE EAR.

HUGO FREY, M.D.
Assistant to Professor Politzer.
VIENNA.

The instrument shown in the illustration has proved very useful to me in making a complete opening into the tympanic cavity—the so-called radical operation. It facilitates especially the removal of the posterior wall of the bony meatus and the outer attic wall. The curve of the hook is made with reference to the anatomic configuration of the parts, so that it retains the membranous meatus close to the anterior walls of the bony canal; the lateral projections holding back the adjacent parts of the auricle.



In using the retractor, the handle should be kept in the direction of the patient's upper lip and somewhat higher than the front part of the instrument.

THE LABORATORY METHOD OF INSTRUCTION.

According to the expressed views of many critics the history of medicine as a science, in contradistinction to an art, is not a long one. One of the greatest steps in securing progress in the science of medicine, it will be maintained, was the introduction into the curriculum of medical schools of laboratory instruction in place of much of the "word of mouth" instruction of the older days. Beginning with anatomy as the first laboratory course in nearly all cases, there have been added courses one by one, until practically every course is now a laboratory course, including the bedside clinic as perhaps the best sort of a laboratory. Even the dry-as-dust subject of osteology has taken on a new life with the introduction of courses in certain schools in which the student constructs a clay model of each bone as it is studied.

It is far from our purpose to attempt to discredit in any way this direction of progress, and we trust that we would have little sympathy if we did, for there is no possible question that both methods and results are far better than they were. But there is a limit to all things, and the best of methods may become faulty when overused. With all new principles one of the first difficulties in finding how far it is to be applied. The problem in the case of this particular form of instruction is by no means a simple one; it is possible that in some instances the laboratory method of instruction has been overdone. As an ideal method of imparting useful information in a valuable way, giving at the same time the highest degree of mental training and the acquirement of practical working knowledge of the subject, there can be little question that laboratory instruction offers the best means at our disposal.

There is, however, one great drawback, the question of time. The problem may be reduced to this: We have as material a person of presumably good intelligence, with a certain amount of training that has provided him with some facts and methods for a working basis. In four years' time that person is to be provided with an equipment that will make him fit, single-handed, to diagnose and treat diseases. This equipment must consist of two things—facts and methods, and it would be difficult to estimate just the relative importance of each. Now it is perfectly certain that the score or more of subjects with which this person must become familiar can not possibly be considered exhaustively, and likewise each must be properly condensed with due regard to the relative importance of its fellows. It is here that the laboratory method leads into difficulties. Take, for example, physiology: Of the innumerable important facts of physiology there are few that are not proper subjects for laboratory demonstration, as they have nearly all been acquired in this way. For a proper understanding of the work that is to follow the student needs to know a very large proportion of these important facts, and there is no doubt that if he could develop each fact for himself in the laboratory he would be fitting himself splendidly; but to do this he would have to repeat to a large extent the entire history of physiology, a performance that would require for itself more than the entire four years assigned to the entire study of medicine. The same thing may be said of pharmacology, and for that matter every course in the curriculum.

Evidently, then, instruction must be given in two ways: in the laboratory, to introduce method, deductive powers, and manual training; in the class room, to present in compact form the necessary facts, and in this way to give to the student the results of the labors of his teachers, their colleagues, and their predecessors. The difficulty lies in the proper apportionment of the time of each course between these two sides. Because of the evident value of training afforded by the laboratory, its development of ideals and idealists, and because the teacher secures for himself the greatest benefits from the laboratory, there is often a tendency to have the student spend all or nearly all of his time in this sort of work. The result is that his knowledge of the subject as a whole is extremely meager, although he may have certain principles well established. We have known students from certain institutions whose whole conception of physiology seemed to lie in nerve-muscle preparations, while their ideas concerning metabolism were correspondingly deficient. The student from another school, on the other hand, having studied physiology under a physiologic chemist, will be found able to trace nitrogen most exactly from corned beef to urea, but hardly know the difference between a reflex arc and the cardiac systole. This sort of thing is far from uncommon, and is largely the result of putting too great stress on the laboratory and too little on the lecture and the recitation.

Another danger that we have noticed is that of leaving the student too much to himself. With the laudable object of permitting self-development, in many laboratories the student is given his material, a few printed directions, and left to his own devices. As a result he often spends many fruitless hours because of starting wrong, that might have been saved by a little guidance. We all learn most by making mistakes, and undoubtedly the student profits by his, but the time element enters in—he must get the facts somehow, and wasted time is wasted opportunity. Again, the long hours demanded by the laboratory leave too little time for the student to assimilate, to correlate, and in short, to think. Too often the result is that he looks on his laboratory work as merely a set task, that is to be performed according to a certain set of directions, and that ought to yield certain results, while the principles involved he is very likely to overlook.

We would not be misunderstood. Laboratory methods of instruction have added vastly to the present and the future of medicine, as of all other sciences, and they will add yet more. But we believe that there is still an important accessory work, made necessary through the brevity of life, that must be performed in the class room, and that in some instances this has been lost sight of, or minimized, with unfortunate results.

PREVENTION OF PNEUMONIA.

One great fundamental principle of preventive medicine is to keep infection from spreading beyond the sick. This principle has long been recognized in the case of very contagious diseases, such as smallpox, measles, etc., and here the methods employed are as yet purely empirical. In recent times the same principle has been applied to other diseases, like tuberculosis, typhoid fever, cholera, dysentery, etc., and in these the practical methods employed are the direct outgrowth of scientific investigations. Thus no conscientious physician at the present time would release a convalescent typhoid patient from restraint so long as the urine contains typhoid bacilli.

Pneumonia appears to be one of the last of the great infectious diseases to be put under the full domination of the principles of prevention of further spread.

The frequency and fearful destructiveness of pneumonia make it absolutely imperative that much greater attention than heretofore must be given to problems connected with its prevention. Too long have we remained content with laying the responsibility for pneumonia at the door of atmospheric conditions of various kinds. While the problems of prevention in this case are complex and difficult, it must be acknowledged that various simple but nevertheless important precautions against the spread of pneumonia have not been carried out systematically, because careful consideration has not been given to this aspect of the disease.

It should be clearly understood that pneumonia—meaning, of course, acute lobar pneumonia—is a pneumococcus disease. If it were possible to destroy all pneumococci pneumonia would disappear. The etiology of pneumonia has been associated with several organisms, of which the pneumococcus was always given the first place as regards importance. Recent investigations show that pneumococci always are present in the blood during life in pneumonia. Thus in one hundred and thirty-two cases giving positive blood cultures during life, Rosenow[1] obtained only pneumococci. In the prevention of pneumonia special and particular attention must always be given to the pneumococcus as the specific causative agent.

Now the pneumococcus is an organism of variable virulence and viability. From laboratory experiments we know that virulence and viability are best preserved when the organism is grown on media containing hemoglobin, a condition furnished to a certain extent by the rusty sputum of pneumonia. We know further that when pneumococci are passed through one susceptible animal after another they soon reach an almost incredible virulence. For these reasons pneumococci in pneumonic sputum may be highly virulent for human beings. This may be the case also of pneumococci from cases of rhinitis, tonsillitis and bronchitis. Hence sputum from all pneumococcal affections of the respiratory tract, and especially pneumonic sputum, should always be treated as infectious. Small endemics of pneumonia and cases of so-called contact infection are no doubt often most readily explained as the result of dissemination of pneumonic sputum containing virulent pneumococci. To permit pneumonic or other infectious sputum to dry is, of course, in direct violation of the first principles of preventive medicine. Certainly the growing feeling that more complete isolation of pneumonic patients is desirable should be stimulated.

Whether all pneumonia can be traced to dissemination of pneumococci by way of sputum and otherwise, is, of course, at present a most difficult question, because we do not know the significance of the pneumococci generally stated to be present in the oral cavity of a large percentage of healthy individuals. Whence do these pneumococci come and how long do they stay? May such pneumococci give rise to pneumonia in their host, and if so, what are the special circumstances that favor such action? These are exceedingly important problems that offer rich fields for investigation. In the light of our present knowledge, however, sputum is the most fertile source of pneumococci that may have increased in virulence from residence within the human organism, and for this reason, as well as for others, the efforts to train humanity to more hygienic habits of expectoration must be vigorously continued.

THE ACTION OF SALINE PURGATIVES AND DIURETICS.

Following his report[1] of last year on the action of certain saline purgatives, J. B. MacCallum has recently carried out some further researches[2] on these substances, and also on certain saline diuretics. It will be remembered that in his former communication MacCallum brought out several facts which greatly altered our conception of the action of saline purges. He showed that such purgatives act, not only when introduced through the intestinal tract, but also when introduced through the skin. He further pointed out that the purgative action of the salts was partly due to increased peristalsis and partly to the increased secretion of fluid into the intestine, both of which processes he observed directly. He compared the action of these salts on the intestine to their action in producing nervous hypersensitiveness and muscular twitching in voluntary muscles, phenomena which Loeb's work has made well known. He likewise showed that the salts of calcium, which counteract the action of the purgative salts on voluntary muscles, have the same effect on intestinal muscle, and he suggested the possible usefulness of calcium salts in nervous diarrhea. He pointed out the dangers attending the use of the barium and magnesium salts, and the apparent harmlessness of the sodium salts.

---

[1] Journal of Infectious Diseases, 1904, i, 280.

[1] American Journal of Physiology, vol. x, No. 3.

[2] University of California Publications, vol. i, Nos. 10, 13, 14.

In his latest work MacCallum has studied the effect of the same series of salts on loops of intestine completely isolated from the body. The object of this work was to study particularly the effect of the salts on the secretion of fluid into the lumen of the intestine. The results which were obtained were completely confirmatory of his first series of experiments. The salts which act as purgatives produce increased peristalsis in a loop of intestine removed from the body and placed in solutions of them, and in certain strengths they also cause the secretion into the intestinal lumen of a fluid resembling intestinal juice. In this set of experiments also the effect of the saline purges was neutralized by the calcium salts, which stopped the peristalsis and prevented the secretion. One practical point is suggested by MacCallum as the result of these experiments, and that is that the expulsion of saline enemata, which is so commonly seen and which is due to the peristalsis produced by the sodium chlorid, may be prevented by the addition of a small amount of calcium chlorid to the enema.

In his work on saline diuretics MacCallum used barium and sodium chlorid. He found that sodium chlorid produced a uniform increase in urinary secretion, which was greatly aided by the introduction of small quantities of barium chlorid into the blood. Larger quantities of barium chlorid caused suppression of urine, probably by causing intense contraction of the musculature of the urinary passages rather than by inhibiting secretion. Calcium salts inhibit the flow of the urine just as they inhibit intestinal action.

It would seem from this experimental work that the common factor underlying the action of saline substances as secretory and muscular stimulants, has been discovered, and accounts for the action of these substances on as different structures as the intestinal canal, the urinary tract and the salivary glands, which have as common elements muscular and secretory structures.

THE INTERSTITIAL GLANDS OF THE TESTICLE.

The importance of the internal secretion of the testicles in determining normal development has been recognized for a long time. Brown-Séquard especially emphasized the significance of testicular secretion on the general metabolism of the body. He claimed that the testicles secreted some substance that had a marvelous effect on the body, especially through the nervous system, in maintaining mental and physical vigor. He thought that the seminal fluid may be partly absorbed and taken into the blood, thus permeating the whole body and exerting a specific effect on the organism. Zoth and also Pregel[1] in 1896 appear to have obtained definite evidence of the property of testicular extract to diminish muscular and nervous fatigue resulting from work, and also to lessen subjective fatigue sensations.

In 1840 Leydig discovered between the seminiferous tubules of the testicle groups of cells, which are ordinarily known as interstitial cells. These cells have become well known through the later work of Kölliker, Hansemann, Lubarsch, Reinke and others. A great difference of opinion has arisen in regard to the origin and significance of these cells. Some think that they are the remains of the Wolffian body (Klein). Others think they have the same origin as the germinative cells of the seminiferous tubules, because of the resemblance of the pigment they produce to that of the germinative cells. Waldeyer thought they were plasma cells. The function of these cells is even a more obscure problem. Some attribute to them a trophic function for the seminal cells; others, again, have assumed, without furnishing any proof, that they produce an internal secretion.

Recently some very interesting and suggestive work tending to throw much light on this problem has been done by two French investigators, Angel and Bouin.[2] From their studies they conclude that these cells are glandular elements, giving all the cytologic indications of glandular activity and passing through the phases of a secretory cycle. For this reason they have proposed to call these cells the "interstitial glands" of the testicle. They have performed a number of animal experiments in order, if possible, to differentiate the functions of the various testicular elements. One testicle was removed, and the vas deferens on the opposite side ligated in a number of animals—rabbits, guinea-pigs and dogs. After six months the animals were killed and the testicles examined. They were small and soft. The seminiferous tubules were much degenerated and absent in places. The columns of Sertoli were nearly normal. The interstitial glands, however, were much hypertrophied, often being doubled in volume. Their blood supply was very abundant, and the cells showed signs of great cellular activity. The animals preserved their secondary sexual characteristics and genital activity. This would seem to be due to the interstitial glands of one side having undergone a compensatory hypertrophy, because of the removal of those of the opposite side, and therefore continuing the function of internal secretion. The seminal cells having degenerated, would not be associated with this function.

---

[1] Pflüger's Archiv, vol. lxii, 1896.

[2] Comptes Rendus de l'Acad. des Sciences, 1903-4.

In cryptorchids the sexual characteristics and genital activity are preserved, though no spermatozoa are formed. In these cases the interstitial glands are well developed between the tubules, while the spermatogenic cells of the tubules have disappeared. This is in complete harmony with the experimental evidence given above. When pieces of the vas deferens of young rabbits are resected, in some cases the animals remain small. The genitals are undeveloped, and they have no sexual instinct, resembling in this respect individuals castrated at a young age. The testicles are very small, and the seminiferous tubules retain their embryonic structure. The interstitial cells show marked deviation from the normal, and apparently have undergone a pigmentary degeneration.

These facts put together seem to indicate that the interstitial glands are especially concerned in controlling the development of the so-called secondary sexual characteristics of the male and in the production of testicular infantilism. This is probably done through the influence of an internal secretion, but this is entirely hypothetical.

THE "PATENT-MEDICINE" CURSE.

Under the above title, Mr. Edward Bok, editor of the *Ladies' Home Journal,* devotes a full page in the current issue of that periodical to the patent-medicine evil. He makes an appeal to the Woman's Christian Temperance Union actively to take up the fight against patent medicines on account of the alcohol they contain. While he recognizes that the alcohol curse is not the only bad feature of the evil, he evidently considers it one of the worst, and this is the main point of his article. He does not mince words, but states facts boldly and in a manner that is convincing. Since it appears in a journal with an immense circulation among women, who are more generally given to the patent-medicine habit than men, the article is certain to have a good effect, temporarily at least.

Bok prints a list of 36 different "patents" with the percentage of alcohol contained in each, as given by the state analyst of Massachusetts, and as published by us some time ago. He calls attention to the fact that the patent-medicine habit is one of the greatest curses with the most dangerous results that is inflicting our people, and that sooner or later they will be awakened to the dangers.

While this article only reiterates what has been printed time and again in medical journals, by appearing in a periodical of this nature it will stir up the other side. This it has already done. In the course of the article special reference is made to the wonderful (?) "Dr. Pierce's Favorite Prescription," and the analysis made by the German chemist, Hager, is published. As a result, the R. V. Pierce Company has brought suit against the publishers for $200,000 damages. It will be interesting if this suit can ever be brought to the courts, and if the manufacturers of the nostrum can be placed on the witness stand and compelled to tell what it does or does not contain. As *Harper's Weekly* says: "How much harm, or the contrary, the patent medicines do we do not know, but a serious fight against them is likely to bring it early to light that they are strongly entrenched, not only in the affections of the people, but of the newspapers, which derive from patent-medicine advertisements a revenue that in the aggregate must be enormous." It is here that the secret of the power of patent-medicine men lies. The power of the press of the country is back of it. While this issue of the *Ladies' Home Journal* has been out for three weeks, there has hardly been a newspaper reference to the article except that which refers to the Pierce suit. We may look for smoothly worded denials of the truth of this or that statement in Bok's article, for there will be a quiet but determined effort made to counteract it, and the newspapers will be used in that effective manner which the experienced press agent knows so well. Already such newspaper matter is appearing. In a paper before us is an interview with one of the officers of the Pierce Company in which it is stated, in that goody-goody way, that they are surprised that a reputable magazine would stoop to make such statements as the *Ladies' Home Journal* has made. We are told that this "favorite prescription" is composed of extracts of medicinal plants, roots and herbs which would "not harm the most delicate system."

The following is what Mr. Bok has to say about the relation of the medical profession to the patent-medicine evil:

> Let any woman who reads these words ask her physician as to the truth of the statements made here. Every intelligent physician knows that this article is decidedly within the truth, rather than beyond it. But the physician cannot speak of the patent-medicine curse unless he is asked, because, if he does, he lays himself open to the accusation that he is afraid of these "patent-medicine cures," since their use interferes with his practice. As a matter of fact, the more patent medicines that are used the better it is for the medical profession, since few things in the end bring a man or a woman or their child more surely to the physician than patent-medicine tippling. It is a curse to the patient, but a money-maker to the physician.

We can not resist the temptation to quote the following truths regarding religious journals:

> Yet in these very same so-called religious papers there are official Woman's Christian Temperance Union columns setting forth the "official" news of the organization and its branches. A pretty consistent picture do these two portions of the average religious paper present—advocating, with one hand, alcoholic prohibition, or temperance, and receiving, with the other hand, money for advertising—and thereby recommending to their readers—preparations filled ten times over with more alcohol than the beer which fills them with so much horror in the editorial columns! There are no papers published that are so flagrantly guilty of admitting to their columns the advertisements of not only alcohol-filled medicines, but prepations and cure-alls of the most flagrantly obscene nature, as the so-called religious papers of this country. Unable, owing to their small circulation, to obtain the advertising of discriminating advertisers, they are all too ready to accept the most obscene class of advertising—business which the aver-

age second-rate secular paper would hesitate or refuse to admit into its columns. I am speaking whereof I know in this matter. Beside me, as I write, lie issues of some twenty different "religious" weeklies, the advertising columns of which are a positive stench in the nostrils of decent self-respecting people. Let the Woman's Christian Temperance Union officers counsel its members who subscribe for these papers to compel their publishers to omit these advertisements, and if they refuse, let these people discontinue their patronage of the paper. Such measures would very quickly shut out from publicity the majority of these baneful patent medicines. There is vital, important work here for the Woman's Christian Temperance Union.

BIOLOGIC TEST OF MUMMIES BY SPECIFIC PRECIPITATION.

J. Meyer[1] has made the observation that extracts of muscular tissue of Egyptian mummies give positive results when mixed with precipitating serum of rabbits immunized with human serum. One of the mummies is said to be about five thousand years old. This result serves to establish that the biologic test is applicable to material several thousand years old. On this account it is suggested that this test may prove of value in the study of certain problems in anthropology at the same time as the theoretical and purely scientific interest in specific precipitation certainly increases as its range of applicability widens.

THE VETO OF THE ANTI-CORONER'S BILL IN NEW YORK

The mayor of Greater New York has exercised his prerogative in vetoing the Elsberg bill abolishing the coroner in that city. He objects to an innovation on a time-honored system, and claims that an institution which is the growth of a thousand years should not be destroyed unless it is proven that its substitute is more useful and will stand the test of time as well. There is little fallacy in this that the mayor does not seem to want to recognize. His remarks would apply to any time-honored abuse that has been kept up through interested motives from time immemorial. The fact, moreover, that the medical examiner's plan is working satisfactorily, except, perhaps, to the politicians, in other states and cities is ignored. We have held a rather high opinion of Mayor McClellan's intelligence, and the belief to which we are forced is that his veto of the bill is to please a corrupt political element backing the opposition to the measure. This is not so complimentary a belief as it would be to presume that he was misled, but we regret to have to adopt it.

ANTE-MORTEM SECTION.

We are apparently passing through one of the irregular periodical revivals of the premature burial scare, as has been evidenced by various legislative attempts and newspaper articles. It is a little curious to observe how fearful some people are of being buried alive. They prefer to have their lives extinguished in the most cruel way to taking any chances on such an event. This tendency appears to be well illustrated by the will of the late Miss Frances Power Cobbe, one of the chief apostles of the antivivisection movement in Great Britain. This woman, of considerable literary distinction, it is reported, put in her will, as a condition on which the other provisions were dependent, that she should have her throat cut, including both the carotid arteries and the trachea, before burial. It is well to note[1] "that this operation could be of no advantage to anybody unless she were still alive." In fact, it was practically an instruction to contingent murder and as such should have been sufficient, we think, to invalidate the clause. It is reported that this ridiculously farcical performance was carried out.

THE RELATION BETWEEN CHILBLAINS AND TUBERCULOSIS.

Though relatively frequent in the colder portions of this country, chilblains are usually so trivial in their effect that they receive home treatment and do not come under the notice of the practitioner. As is the case with many minor ailments, we are apt to regard them as having little or no significance, but a little reflection leads to the conclusion that as all individuals who are exposed to cold do not have chilblains there must be some underlying factor in those who suffer from them. Permin[2] has recently advanced the idea that there is an intimate association between tuberculosis and chilblains. Permin's conclusions are based on the study of the patients and attendants at a tuberculosis sanitarium. He found that 70 per cent. of the patients and 60 per cent. of the attendants had chilblains. All of the attendants who suffered were tuberculous or showed evidence of healed tuberculosis. Permin thinks that the lesion is due to the action of the tuberculous toxin on the skin.

EDDYISM AND LITERATURE.

In these days when literature, or at any rate fiction, is utilized as a propaganda for all varieties of art, science, politics and religion, and when the "Christian Science story" is recognized by publishers as appealing to a definite and presumably large constituency, it is encouraging to find that the spread of Mrs. Eddy's vagaries sometimes meets with a hearty rebuff in non-professional quarters. The *Atlantic Monthly* for April contains an analysis of Eddyism, which deserves to be widely read for its literary quality, as well as for its combination of clear exposition and pitiless logic. In the opinion of the author of this article, Eddyism not only "defies the canons of history," but may be shown in addition "to be specious philosophy, superficial science and a caricature on Christianity." The author then proceeds to enlarge on these four counts, and, while studiously preserving a judicial and discriminating attitude, mercilessly lays bare the scientific, metaphysical and historical absurdities of the dogma erected by Mrs. Eddy and her followers. There is no mincing of words: " . . . it is about as likely that the Great Unknown, casting about for a medium for his sanitary pronouncement, should have singled out this bungling prophetess, as that the immortal spirits, dead and not yet born, should find no more profitable occupation than strumming banjos for the delight of mediums too spiritually constituted to engage in honest work." All in all, this contribution will repay perusal.

SCHOOLBOY MOSQUITO BRIGADES.

In San Antonio, Texas, a campaign against the mosquito has been taken up in a rather peculiar way. The health officer of New Orleans, who has been manfully striving to overcome the difficulties in that city, was apparently forced to go out of the city to demonstrate what might be done. He gave lectures at Laredo, San Antonio, Houston and Galveston, and with the coöperation of the superintendent of the Board of Education of San Antonio has started a movement among the school children to fight the mosquito. We have heard of Mr. Sherlock Holmes' Baker street gang, to which he applied sometimes to search out important facts, using the street boys for his purpose. There is very little that escapes a live boy if his attention is called to it. Dr. Kohnke's demonstrations seem to have started the enthusiasm of the San Antonio schoolboys, and it is a wary wiggletail that is going to escape their attention, according to newspaper accounts. It is proposed to carry on the fight on the same plan in New Orleans, using the success of it in San Antonio as an evidence of what can be done elsewhere. We wish Dr. Kohnke success. Under properly regulated supervision, we can see no more successful mosquito brigade than one composed of thoroughly instructed schoolboys indulging their natural destructive tendencies in killing these pestilent insects.

A PRACTICAL RESULT OF ORGANIZATION.

Our attention has been called to the fact that there is at least one American life insurance company that appreciates the value of medical organization. Applicants for appointment as medical examiners to this company furnish their own references in the good old-fashioned way, but, in addition, every applicant is made to stand the test of professional fellowship. Is he a member of his county medical society? What does the secretary of the county medical society say about him? Every honorable physician can be a member of his local society, which society, without further effort on his part, makes him a member of the state medical association. Most physicians now avail themselves of this opportunity, while the unqualified remain outside. To the mind of the medical director the preliminary sifting has been done; there is no need to look for examiners outside the organization. Nowhere is a physician so well known as among his own associates. If they receive him into fellowship it is evident that he is not without character and educational attainment. The time is rapidly approaching, if, indeed, not already here, when the physician who is not a member of his county medical society need expect to receive none of the appointments of honor and profit that come to medical men. This is safe policy, because no longer may a qualified man be excluded from society benefits. Personal prejudice no longer serves to debar a reputable physician from the benefits of medical-society fellowship. The county medical society compels every applicant for professional fellowship to show that he is an honorable man and an educated physician, but it can not refuse admission to any physician in its territory who can thus demonstrate his fitness for membership. Therein lies the value of the society list to the corporation of whatever sort that seeks the professional services of a physician.

ANTISTREPTOCOCCUS SERUM IN SCARLET FEVER.

Not long ago Heubner in Berlin gave his impressions of the use of antistreptococcus serum in scarlet fever.[1] His statements are judicious, non-sensational and apparently wholly fair. Unfortunately his impressions of the value of the serums used (Aronson's, Moser's, Menzer's) are not favorable. Heubner has always believed that while streptococci are not the cause of scarlet fever, yet they are of the greatest importance in determining the mortality and complications of this disease. His experience with the various serums is somewhat limited as to the number of cases (twenty), but the individual cases seem to have been thoroughly well studied. His were selected cases. Those in which improvement succeeded the use of serum were early cases, the exact course of which could not possibly be foretold. In no case did he obtain a distinct impression of unquestioned specific healing by the serum, an experience entirely and diametrically different from that of the first twenty cases of diphtheria he treated with antidiphtheria serum. Heubner's future policy in regard to the use of antistreptococcus serum in scarlet fever is this: Serum may be used only in severe early cases, in which the prospects of recovery by other forms of treatment are minimal. It seems to be generally agreed, even by the rather enthusiastic Viennese observers that antistreptococcus serum has no effect on established complications (endocarditis, arthritis, etc.), and Heubner and Menzer both believe that it is contraindicated in cases with multiple foci of streptococcus localization. Heubner's experience is also valuable, because the serums he used are made according to different methods—Aronson's coming from horses immunized with human streptococci made especially virulent by repeated passages through animals; Moser's from horses injected directly with streptococci isolated from cases of scarlet fever; and Menzer's from horses treated with streptococci isolated from cases of rheumatism.

SPECIAL ATTRACTIONS FOR THE GENERAL MEETINGS.

A new departure will be instituted at the coming session of the American Medical Association, through which the general meetings held each evening will be more varied in character. Heretofore the meetings were devoted simply to orations. This year, on Tuesday evening, beside the Oration on Medicine, the title of which is "The Importance of Pathologic Anatomy in Clinical Medicine," by Dr. George Dock, Ann Arbor, Mich., there will be a symposium on research work in the United States. Dr. J. S. Billings, New York, will give an account of the work being done by the Carnegie Institution; Dr. L. Emmett Holt, New York, will speak of the Rockefeller Institute; Dr. Frank Billings, Chicago, of the Memorial Institute for Infectious Diseases; Dr. Harold C. Ernst, Boston, concerning the research work at Harvard, and Dr. Alfred Stengel concerning the William Pepper Clinical Laboratory. Wednesday evening Dr. W. J. Mayo, Rochester, Minn., will deliver the Oration on Surgery, entitled "The Association of Surgical Diseases in the Upper Abdomen." This will be followed by a symposium on "The Mutual Relations and Duties of the Government Medical Services and the Medical Profession." Dr. Victor C. Vaughan will talk on the subject "What Can the Medical Departments of the Army, of the Navy, and of the Public Health and Marine-Hospital Service Do for Medical Science?" Surgeon-Major William C. Borden, U. S. Army, will speak on "What Can the Medical Profession Do for the Army?" Surgeon C. F. Stokes, U. S. Navy, will speak for the Navy, and Surgeon-General Walter Wyman will speak for the Public Health and Marine-Hospital Service. Thursday evening the Oration on State Medicine will be delivered by Dr. Herman M. Biggs, New York City, on "Preventive Medicine; Its Achievements, Scope and Possibilities." Following this will be a symposium in which Dr. William H. Welch, Baltimore, will speak on "The Bureau of Animal Industry; Its Service to Medical Science"; Dr. D. E. Salmon, Washington, D. C., on "The Service of the Medical Profession to the Bureau of Animal Industry," and Dr. H. W. Wiley, Washington, D. C., on "The Bureau of Chemistry and Medical Science." These evening meetings will be held on Young's Pier, so there will be ample room for the large number that will certainly attend them.

---

[1] Berl. klin. Woch., 1904, 41, p. 372 (Gesellschaft der Charité-ärzte).

Medical News.

CONNECTICUT.

Connecticut Members of the American Medical Association.—This association, organized for social purposes, holds a meeting annually, preferably at some seaside or country resort, which is simply an outing for a social good time, and to foster friendly personal relations. Every member of the Connecticut Medical Society is cordially urged to become a member. Information regarding this association may be obtained by addressing the secretary, Dr. J. M. Keniston, Hartford Hospital, Hartford, Conn.

DELAWARE.

Health and Other Appointments.—Drs. Peter W. Tomlinson and James A. Draper, Jr., have been appointed members of the Wilmington Board of Health, and Dr. Tomlinson has been elected president.——Dr. Henry W. Briggs, Wilmington, nominee of the president and fellows of the Medical Society of Delaware, has been appointed a member of the State Board of Medical Examiners.——Drs. L. August H. Bishop, William F. Davis and James H. Wilson have been appointed members of the Dover Board of Health.——Dr. Hiram R. Burton, Lewes, has been reappointed a trustee of the State Hospital for the Insane.

DISTRICT OF COLUMBIA.

Health of the District.—The report of the health officer for the week ended May 7, shows the total number of deaths to have been 104, 57 white and 47 colored; 122 births were reported, 67 were white and 55 colored. At the close of the week 9 cases of diphtheria, 26 of scarlet fever, 44 of typhoid fever, and 4 of smallpox were under treatment.

Health of the Panama Route.—Dr. J. C. Perry, surgeon U. S. P. H. and M.-H. Service, who recently submitted a report on the morbidity, prevailing diseases and mortality in the cities of Colon and Panama, has recently made a report on the prevailing diseases on the isthmus along the route of the canal, with special reference to the morbidity among the employes of the French canal company. The report is valuable and interesting, and is published in volume 19, No. 18, of April 19, 1904, of the Public-Health Report. This is a public document and will be mailed free on application to Surgeon-General Walter Wyman, Washington, D. C.

Qualifications and Reciprocity.—Senator Gallinger has introduced a bill to amend the act of 1896 regulating the practice of medicine in the district and providing for reciprocity. The chief provisions of the bill are as follows:

> No applicant shall be licensed who is not of good moral character and free from mental defects and drug habits liable to interfere with the proper practice of medicine and surgery. Nor who, at the time of making application and for not less than two years prior to the date thereof, has not been lawfully authorized to practice medicine and surgery, and actually engaged in such practice, in the jurisdiction wherein he resides..
>
> Nor unless the applicant acquired the right to practice medicine and surgery in such jurisdiction under conditions equivalent to those with which he would have had to comply, in order then to have practiced medicine and surgery in the District of Columbia.
>
> Nor unless the jurisdiction by virtue of whose license the applicant seeks exemption from examination in the District of Columbia grants to licentiates of the Board of Medical Supervisors of the District privileges equivalent to those which the applicant seeks.
>
> Nor until the applicant has paid to the Board of Medical Supervisors such fee as may be fixed and required by the regulations of the board, but not more than the fee charged under similar circumstances by the jurisdiction by virtue of whose license the applicant seeks exemption from examination.

ILLINOIS.

Fifty Years in Practice.—On May 3, Dr. David M. McFall, Mattoon, began his fiftieth year of practice. He has been in Mattoon for 41 years.

Langdon Arrested.—"Dr." Peter R. Langdon, Kankakee, for whose apprehension a reward of $200 was offered, was arrested at Queenstown, Ireland, May 5, as he landed from the steamer *Majestic*.

Must Not Spit in Bloomington.—Bloomington has adopted an ordinance prohibiting expectoration on sidewalks, in public buildings, or in stores or private dwellings "against the consent of the owner, agent or occupant thereof."

Chicago.

Gift to Children's Hospital.—Mrs. Porter has given $75,000 toward a new building for the Maurice Porter Hospital, which henceforth is to be known as the Children's Memorial Hospital.

Lying-in Dispensary Opened.—The new dispensary erected by popular subscriptions for the Chicago Lying-in Hospital, at a cost of $20,000, was formally opened May 3. The nurses and internes of the hospital gave a gold loving-cup to Dr. Joseph B. DeLee, founder of the institution.

Summer Courses at University of Chicago.—Special courses covering the anatomy of the ear and nasal cavities, the anatomy of the larynx, and the anatomy and pathology of the eye, will be offered at the University of Chicago during the the middle of June.

INDIANA.

Hospital Addition Opened.—The addition to the Marion Hospital, which has been erected at a cost of $15,000, was formally opened April 20.

Dies on Eve of Graduation.—Clifford O. Burroughs, a senior student of the Medical College of Indiana, who had won distinction by the high character of his work, died April 18, at the Deaconess Hospital, Indianapolis, from typhoid fever, after an illness of 18 days, aged 22.

License Revoked.—On April 26, the State Board of Medical Registration revoked the license to practice of Dr. Eva R. Templeton, Indianapolis, because it was alleged she was a graduate of the Independent Medical College, Chicago, and obtained the permit to practice by irregular means.

Many Graduate.—Central College of Physicians and Surgeons, Indianapolis, graduated a class of 21 April 20. Dr. George D. Kahlo, dean of the faculty, presented the diplomas and Hon. Vinson Carter presided.——At the annual commencement exercises of the Medical College of Indiana, Indianapolis, April 22, Winfred E. Garrison, president of Butler College, delivered the address, and President Addison C. Harris of the University of Indianapolis presented diplomas to a class of 82.

Personal.—On April 20, Dr. William W. Wickham, Goshen, celebrated the fifty-seventh anniversary of his advent in that city.——Dr. and Mrs. Amos L. Wilson, Indianapolis, celebrated their fiftieth wedding anniversary April 25.——Dr. Kenneth I. Jeffries, interne at the Indianapolis City Dispensary, has resigned to accept the position of assistant superintendent of the Eastern Indiana Hospital for the Insane, East Haven, near Richmond.——Dr. John N. Hurty, Indianapolis, secretary of the State Board of Health, is confined to the house with a third attack of appendicitis.

LOUISIANA.

Endorses Heyburn Bill.—The Bossier Parish Medical Society, at its meeting, April 12, endorsed the Heyburn pure food bill.

Additions to Portrait Gallery.—At the annual meeting of the trustees of the Eye, Ear, Nose and Throat Hospital, New Orleans, May 4, portraits of Gen. W. G. Vincent and Hippolyte Larouissini, first and second vice-presidents of the hospital, were unveiled.

Munificent Bequest to Tulane.—By the terms of the will of the late A. C. Hutchinson, the bulk of his estate, valued at nearly a million dollars was left to Tulane University Medical Department, and the Supreme Court of the State has decided that the college shall receive the bequest.

Tulane's Commencement.—At the annual commencement of the medical department of Tulane University, New Orleans, May 4, a class of 91 received diplomas from President Edwin A. Alderman. Prof. C. A. Smith, dean of the graduate department of the University of North Carolina delivered the annual address.

Establishes Detention Camps.—Dr. Edmond Souchon, New Orleans, president of the State Board of Health, accompanied by Dr. Charles P. Wertenbaker, U. S. P. H. and M.-H. Service, made an official visit of three days to Northwest Louisiana and established five detention camps to be used in case of an outbreak of yellow fever in Texas.

MARYLAND.

Baltimore.

To Fight Smallpox.—Health Commissioner Bosley has been allowed $2,000 by the board of estimates, to fight smallpox; during April he spent $1,200 in this work.

Rockefeller Gift.—The $500,000 Rockefeller gift has been received by the Johns Hopkins Hospital trustees. It covers the net loss by the fire, and will be used in rebuilding the 70 warehouses burned down.

Vital Statistics.—The deaths during April were 898, the largest number in four years. Fourteen cases of smallpox were reported, and scarlet fever was prevalent.——For the week ended May 7, 5 cases of smallpox were reported. In the mortality list, 36 deaths were credited to pneumonia and 34 to consumption.

Commencements.—At the Maryland Medical College commencement, May 5, there were 104 graduates. The prizes were given as follows: First, Frank W. Hachtel; second, George W. Shriver; W. S. Smith prize, I. A. Baker; B. A. Muse prize, I. H. Russell; Harry Gross prize, M. Abi-Massoud, Syria, and O. O. Eackle. Hon. John H. Poole, ex-United States senator, of Colorado, was orator.——The Baltimore Medical College graduated 75 May 5. Dr. Emil Novak received the highest prize, the college medal; Dr. G. E. McPherson, the Robert W. Johnson surgical prize; Dr. Emil Novak, the William E. Moseley gynecological prize, and Dr. E. E. Houck the A. C. Pole anatomical prize. There were 500 students enrolled last year. Dr. Bernard Skeiner delivered the address.

Personal.—Dr. George W. Hemmeter has been appointed health warden of the Sixteenth Ward, vice Dr. Howard D. Lewis, resigned.——Dr. Charles R. Bardeen, associate professor of anatomy at the Johns Hopkins Medical School, has been appointed professor of anatomy at the University of Wisconsin.——The following have been made police surgeons: Dr. Wirt A. Duvall, chief surgeon: Drs. J. Claggett Robertson, John D. Norris, Andrew H. Whitridge and H. Lee Smith.——Drs. Frank W. Hachtel and Charles E. Benson have been appointed resident physicians at Franklin Square Hospital, and Dr. J. Asley Gilmer, resident physician of West End Maternité Hospital.——Dr. Francesco del Valle, who has resided here several years, has returned to Puerto Rico, where he will be assistant director of the Department of Health, Charities and Correction.

Library Report.—The report of the librarian of the Medical and Chirurgical Faculty of Maryland shows that the library now contains 13,833 volumes, 4,449 being bound journals. This does not include several thousand duplicates. There are 5,301 unbound monographs and reprints. The accessions for the year were 694; 1,585 books were borrowed and 4,501 readers were registered. The library receives regularly 152 journals. The work of the exchange of the Association of Medical Librarians has been carried on during the year, the lower hall being crowded with books and journals for that purpose. All the old and rare books have been placed in locked cases and can not be removed except by special permission. The income for the year was about $2,500, including faculty appropriation, the Frick fund, receipts from book and journal club, fines, sales, etc., and the expenses were about the same amount.

MASSACHUSETTS.

New Surgeon General.—Lieutenant Colonel Otis H. Marion, Allston, was appointed surgeon general of Massachusetts, May 2, vice Brigadier General Robert A. Blood, Charlestown, retired.

Guilty, and Defaults.—Dr. George S. Hatch, Boston, who was convicted in the Superior Criminal Court, April 26, of causing the death of Mary A. Welch by a criminal abortion, failed to appear when called for sentence April 29.

Dinner for Ehrlich.—On April 23, Drs. William T. Councilman, David W. Cheever, Franz Pfaff, and other Boston physicians, gave a dinner in honor of Professor Ehrlich of Berlin. President Eliot of Harvard University was also a guest of honor.

Antivivisectionists Again Defeated.—The efforts of the antivivisectionists this year again met final defeat, when in the house of the Massachusetts legislature, May 4, the adverse report of the probate and chancery committee was accepted and the bill desired by the petitioners was rejected by a vote of 35 to 90.

Loss Made Good.—St. Luke's Home for Convalescents, Boston, which lost about $40,000 through the defalcation of its treasurer, has already had this sum made good by gifts, and is doing its usual good work, especially for women, who, on their discharge from hospitals, are cared for a few weeks until they are again able to work.

Anniversaries.—On the occasion of his sixtieth birthday, May 2, friends of Dr. James R. Foster, North Attleboro, tendered him a reception and banquet and presented him with a handsomely equipped traveling bag.——Dr. and Mrs. Samuel Pitcher, Hyannis, celebrated the fifty-seventh anniversary of their marriage, March 30.

Personal.—Dr. Louis L. Bryant, Cambridge, was presented with a handsome dining-room set, April 25, by professional and lay friends.——Dr. Thomas B. Shea has been appointed a member of the Boston Board of Health.——Dr. David E. Harriman, South Hadley Falls, has been appointed associate medical examiner of the third Hampshire district.

Regulates Milk Supply.—The Boston Board of Health has made new regulations in regard to the milk supply. Henceforth milk may be condemned which has over 500,000 bacteria to four cubic centimeters, or a temperature exceeding 50 degrees. These regulations apply to all places where milk is on sale, such as stores, bakeries, restaurants, etc.

Fine and Imprisonment.—Dr. Robert Surles, who was recently released from state prison after serving seven years for performing a criminal operation, was sentenced, on April 26, at Worcester, to pay a fine of $500 and to serve three months in the house of correction for practicing medicine without a certificate from the Board of Registration in Medicine.

State or National Responsibility.—A case of leprosy discovered in Harwich, admitted from Portugal, through the port of New Bedford and now under the call of the State Board of Health, has raised the question whether, if it can be proven that he gained entrance through the neglect of the United States officials, the United States Government can be held for the expenses incurred by the state in his case.

NEW YORK

Medical Examiners Reappointed.—The regents have reappointed as medical examiners Drs. Joseph P. Creveling, Auburn, and Dr. Eugene Beach, Gloversville.

Fire Loss.—In the recent fire at Thousand Island Park, the cottage of Dr. Frederick Clark Bailey of Adams Center was destroyed, and that of Dr. Henry W. Carpenter of Oneida, was damaged.

House Physicians Appointed.—Drs. Harold E. Hoyt, Cambridge, and Frank E. White, Union, have received appointments on the house staff of Ellis Hospital, Schenectady.——Drs. Charles Moore, John Mehnert and August Schlappi were appointed house physicians to the German Hospital, Buffalo.

More Alleged Manhattan State Hospital Abuses.—Coroner Nicholas T. Brown, in discussing the recent case of Abraham Wendorff, who had eight ribs fractured in that institution, said that the fact that the nurses were underpaid, incompetent and inexperienced was no excuse for such an occurrence. The physicians who permitted these brutalities were responsible.

Bills of Medical Interest Signed.—On May 3 Governor Odell signed bills, giving the state medical and county medical societies authority to adopt suitable by-laws; permitting medical societies to fix the qualifications for membership, and permitting the holding of autopsies on public patients in the Craig Colony of Epileptics if the bodies are not claimed 48 hours after death.

Health Officials Hold Office Illegally.—With the exception of two or three cities all the city health officers in the state are appointed under a state law. That law was amended a year ago last winter and, accidentally, the clause providing for appointing health officers was left out. The mistake was rectified by a bill passed at the close of the recent session. The question now arises whether the bill which legislated the office out of existence did not drop all health officers, and whether the men now in office are legally in power. If not, they will all have to be reappointed according to lawyers who have looked the matter up.

New York City.

Anonymous Gift.—New York University has received an anonymous gift of $12,500 for its medical department.

Jewish Hospital To Be Enlarged.—The Jewish Hospital has made arrangements for building an extension, to cost $10,000.

Convalescent Home.—A home for poor convalescents is to be opened and will be under the care of the Carmelite Sisters. It is to accommodate those who have been discharged from the hospitals and are still too ill to work.

Given Loving-Cup.—Dr. William T. Bull delivered his last lecture as professor of surgery at the College of Physicians and Surgeons, May 4, and was preseented with a handsome loving-cup by the students of the junior and senior classes.

Gift to Columbia University.—Horace W. Carpentier has given $60,000 for the endowment of the Carpentier Professorship of Pediatrics in the medical school in memory of his brother, Dr. Ruben S. Carpentier. Dr. L. Emmet Holt is he incumbent of this chair.

erebrospinal Meningitis.—Within four days 18 cases of ebrospinal meningitis were reported. This alarming spread the disease has been mostly among the children of the tenements of the upper East Side. There were more than a dozen cases in Mt. Sinai Hospital during the past week.

Eye and Ear Infirmary May Close.—Since the meeting of the Trustees of this institution last month, practically no additional gifts have been received. Unless $80,000, the annual expense of the hospital, is forthcoming, it will have to be closed in September at the close of the fiscal year.

Fraudulent Vaccination Certificates.—Health Commissioner Darlington has issued a warning to parents against buying certificates of vaccination, which were on sale for ten cents each. There was no evidence that dispensaries had charged for such certificates, but there was proof that several physicians had sold them.

Tuition Too High.—The increase in tuition rates from $200 to $250 a year at the College of Physicians and Surgeons of Columbia University is alleged to be the reason why 98 students of that institution have announced their intention of going to other colleges for the remainder of their medical course.

Coroners Will Remain.—Mayor McClellan has vetoed the bill legislating the coroners out of office and substituting medical examiners. His reasons were that it was an innovation on a time-honored system, and was so far a mere experiment. The proponents did not, in his opinion, defend their measure successfully nor answer the objections as to its justice, humanity, economy or efficieency. The abuses that had crept into the present system might be remedied by legislation without destroying the system.

To and From Europe.—Dr. Carl Fulda, Brooklyn, arrived, April 27.——Dr. and Mrs. Valentine Mott and Dr. and Mrs. H. D. Weller and Drs. Joseph L. Anderson, S. Baxter, J. C. Logan and D. L. Gibson sailed May 5.——During the past week Dr. J. C. Roberts of the New York Board of Health arrived on the *Teutonic*, and Dr. and Mrs. J. O. E. King and Dr. S. W. Werner sailed from Hamburg.——Dr. and Mrs. F. W. Eaton and Dr. Charlton Wallace arrived from the Mediterranean.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended April 30, 1,398 cases of measles, with 46 deaths; 490 cases of tuberculosis, with 199 deaths; 419 cases of scarlet fever, with 26 deaths; 409 cases of diphtheria, with 62 deaths; 44 cases of varicella; 6 cases of smallpox; 40 cases of typhoid fever, with 6 deaths, 30 cases of cerebrospinal meningitis, with 7 deaths, and 380 cases of pneumonia, with 234 deaths.

Typhoid-Fever Map of New York.—The Board of Health has prepared a most interesting map of Manhattan Borough, to be sent to the St. Louis Exposition, illustrating the methods of the New York Health Department in fighting typhoid and other contagious diseases. The whole display, it is said, will be the largest and most complete display of health department work ever assembled in this country. The typhoid chart shows every case that has been reported this year. By the color of pins the history of what is known of the origin of each case is told. One striking fact brought out by the chart is that the region between Fourteenth and Forty-second streets, and for several blocks on either side of Broadway was almost exempt from the disease. The number of cases in Manhattan from January 1 to April 1 was 200, against 446 for the corresponding period of last year.

NEW JERSEY.

Smallpox in Gloucester.—Three cases of smallpox were reported in Gloucester City during the week. These are all in one family. The malady is said to have been contracted in Philadelphia.

Jersey City Health Board.—Drs. Gordon K. Dickinson, Frank D. Grey, George E. McLaughlin, Joseph M. Rector, John P. Henry, Fred E. Lambert, a plumber, a dentist and the president of the Hudson County S. P. C. A., make up the personnel of the new board of health of Jersey City.

Society Elections.—CAMDEN COUNTY MEDICAL SOCIETY.—At the annual meeting of the society, April 25, the following officers were elected: President, Dr. Joseph H. Wills, Camden; vice-president, Dr. William A. Westcott, Berlin; secretary, Dr. Paul M. Mecray, Camden; treasurer, Dr. Joel W. Fithian, Camden; historian, Dr. Alfred Cramer, Camden; reporter, Dr. Ezra B. Sharp, Camden; censors, Drs. Harry H. Sherk and William A. Davis, Camden, and trustee, Dr. Edmund L. B. Godfrey, Camden.——SALEM COUNTY MEDICAL SOCIETY.—At the annual meeting the following officers were elected: President, Dr. John F. Smith; vice-president, Dr. Clifford M. Sherron; secretary and treasurer, Dr. Henry Shavanne; reporter, Dr. William H. Carpenter; censors, Drs. Nathaniel S. Hires, Richard M. A. Davis and B. Bilderback, all of Salem.

PENNSYLVANIA.

Personal.—Dr. Daniel W. Shelly has been elected medical inspector of Ambler.——Dr. William B. Ulrich, Chester, was tendered a reception, May 4, in honor of his seventy-fifth birthday anniversary and his golden wedding.

Arrest of Illegal Practitioners.—Dr. Henry Beates, Jr., president of the State Board of Medical Examiners, reports the arrest of three illegal practitioners. One is Thomas C. Eldridge, who exhibits a fraudulent license from the state of Michigan, who has been practicing very successfully, so far as money returns are concerned, and also has killed one patient. The other two are candidates who failed before the State Board of Medical Examiners, on more than one occasion, and nevertheless established themselves in practice. The state of the public mind is such, at last, in Pennsylvania, as to enable these cases to be successfully pushed to the full extent of the law. The only regret is that the Act of Assembly, governing practice in Pennsylvania, has not a punitive clause, which, in addition to the fine of $500 for each offense, should have latitude from that figure to at least $2,000 and imprisonment of from one to five years, to be determined by the discretion of the court. The lay press of Philadelphia is at last publishing the practices of these illegal "clinicians." The following is a statement of the legal aspects of the prosecution:

> The state of Pennsylvania is infested with charlatans and quacks, and in this respect is no exception to other states, who attempt to avoid the law which governs the practice of medicine, and who have successfully thus far done, taking advantage of a technical interpretation of what constitutes the practice of

medicine, which a judge, some years ago on the supreme bench of the state of New York gave. The decision was that the practice of medicine consists in the treatment of disease by the use of medicine.

The inference drawn from this definition is that anybody who proclaims and professes to be able to treat disease, without the use of drugs, is not amenable to the law. The United States report for 1888 contains the decision of Chief Justice Field, who spoke for the unanimous opinion of the U. S. Supreme Court. In that opinion the common practice of law is enunciated, which demonstrates and clearly proves the constitutionality of all statutes which require proof of the possession of qualification on the part of everybody who offers his services and assumes the responsibilities for the treatment of disease, deformity and injury.

Any one, therefore, who so poses before the public, by any means whatsoever, who is not a licentiate of any commonwealth, is an illegal practitioner. Pennsylvania, acting on the principle of the law involved, has proceeded to prosecute all individuals concerning whom there is unmistakable proof of their posing as physicians who do not possess the license issued by the state.

In the preliminary hearings before the magistrate the presentation of these facts has resulted in every case thus far apprehended, in being held in bail for trial in court. It would be well for every state recognizing the facts and the involved principles to know that anybody following a vocation for a livelihood which involves the interests of fellow man, must possess a license from the state, which license is the state's guarantee of qualification.

As soon as this principle becomes generally recognized both by the laity and by the profession, the end of the fake physician, quack or charlatan is determined.

The question could well be raised, whether or not persons patronizing those not possessing a license are thus not guilty of misdemeanor against the laws of the commonwealth. Nothing in this restriction can be regarded as class legislation. The conditions are alike for all and consequently will happen to all who may desire to enter the profession of medicine. The law is just in requiring compliance with these conditions, which the state by common consent and the enactment of statutory laws, established as a standard requirement of qualification.

Philadelphia.

Personal.—Dr. Harry B. Brusstar sailed April 30 for Bad Nauheim, Germany. On account of failing health, his physicians have advised abstinence from practice and absolute rest.

City Virus Plant Contemplated.—The city is considering the establishment of a $40,000 plant for the preparation of vaccine virus to combine with that for the manufacture of diphtheria antitoxin.

Treves on a Tour.—Dr. J. William White leaves for San Francisco in a few days to meet and accompany across the continent Sir Frederick Treves, who will arrive in San Francisco in June. He will leave Philadelphia the latter part of June, and will be accompanied by Dr. White and his family to Liverpool.

Address on the Navy.—Dr. R. A. Marmion, medical director, U. S. N., addressed the students of the Medical Department of the University of Pennsylvania May 5, on the work in the Medical Corps of the Navy and the inducements and advantages now held out for candidates for the service. His lecture treated of the work of the corps, the condition of life and recent improvements in the service. He spoke also of the special training received by candidates in the medical service school.

Dishonest Student Expelled.—The faculty of the Medico-Chirurgical College have expelled a member of the senior class, who was charged by the county medical society with practicing medicine illegally. The society is adopting rigorous measures to bring to justice the men who are guilty of this misdemeanor. During the past week several arrests have been made of men who have been practicing medicine illegally; of men who have not passed the required state examination. Several more arrests are to be made. All the men thus far brought to justice have been held in bail for their appearance at court.

Health Report.—A slight abatement in the prevalence of typhoid fever has been noted; 277 new cases and 38 deaths were reported during the last week. This indicates that the progress of the disease has been checked. Smallpox continues throughout the city; 26 new cases were reported and 5 deaths. Deaths during the week numbered 572, a decrease of 20 from last week and an increase of 74 over the corresponding week of last year. This total is made up largely of pneumonia and other lung diseases, 193 deaths being attributed to these causes alone. There were 86 deaths from pneumonia. This has been about the average since January 1.

To Study Tuberculosis in Europe.—Prof. Leonard Pearson, state veterinarian, and Dr. M. P. Ravenel will go abroad under the auspices of the Phipps Institute, to investigate the methods of Professors Maragliano of Italy, Thomasson of Holland, Baregs of Sweden, McFadyan of England, Marmorek of Paris, and Behring of Marburg, in the treatment of tuberculosis. Drs. Ravenel and Pearson will also spend a few months' study with Professor Neuseld in Koch's Laboratory in Berlin. The investigation is to be devoted almost exclusively to the study of inoculation and vaccination methods. The data and knowledge gained are to be tabulated and arranged, and will be given to the profession by the Phipps Institute.

Samaritan Hospital Clinics.—The board of trustees and the medical staff of the Samaritan Hospital, Broad and Ontario streets, invite the delegates and members of the American Medical Association to attend a special series of clinics to be held in the amphitheater of the hospital during the week immediately following the meeting of the Association in Atlantic City. The following program is announced: Monday—Surgical, by Dr. W. Wayne Babcock at 8:30 p. m.; Tuesday—Medical, by Dr. Samuel Wolfe at 8:30 p. m., and Obsteric, by Dr. John C. Applegate at 9:30 p. m.; Wednesday—Gynecologic, by Dr. Wilmer Krusen, at 8:30 p. m.; Thursday—Ophthalmologic, by Dr. John W. Croskey, at 8:30 p. m.; Friday—Gastrointestinal, by Dr. Boardman Reed at 8:30 p. m., and Genitourinary, by Dr. Loux at 9:30 p. m.

Sherrington's Address.—Prof. Charles S. Sherrington, M.D., of the University of Liverpool was the guest of the University of Pennsylvania, May 5, and delivered a lecture on "Cerebral Localization," which was of special interest because of his description of his investigations on the brain of a gorilla, the only experiment of the kind on record. This experiment cost about $2,000, and continued uninterruptedly from 4 o'clock of the morning of one day until 2 o'clock of the morning of the subsequent day, the animal being under the influence of chloroform during the entire period of the experiment. The results of this experiment led Professor Sherrington to delimit the psychomotor regions, eliminating the posterior central convolution, and suggesting certain minor changes in other areas. After the lecture Professor Sherrington was entertained at dinner at the University Club.

Hospitals.—During April the Polyclinic Hospital treated 1,959 new cases in the dispensary, and 6,517 return visits were made, making a total of 8,476 cases treated; 615 patients were treated in the receiving ward, and 128 patients were admitted to the hospital wards.——In the Episcopal Hospital there were 255 patients admitted to the wards and 7,056 patients treated in the dispensary.——In the Pennsylvania Hospital there were 365 patients in the wards; 1,587 were treated in the receiving ward and 1,599 in the dispensary, making a total of 3,551 for the month. The work done during the year 1904 in the Pennsylvania Hospital is as follows: In the wards, 4,337; receiving wards, not remaining in the house, 21,406; out-patient department 17,290, making a total of 43,033; an average of one case every twenty minutes, night and day throughout the year applied at the receiving wards for treatment.——In the Presbyterian Hospital there were treated 410 patients, 210 of whom remain in the institution; 93 ambulance calls were made, and 2,053 patients were treated in the dispensaries.

GENERAL.

American Urological Association.—The annual meeting of this association is to be held at Atlantic City, June 8 to 9.

Typhoid Among Marines in Cuba.—An epidemic of typhoid fever is reported among the American marines in eastern Cuba.

American M.D.'s in Germany.—The German supreme court forbids the use of the title "Doctor" in Germany, when granted in the United States.

Reorganization of Red Cross.—A scheme has been proposed whereby a new charter will be issued to the Red Cross Society, with various changes in the plan of management.

American Therapeutic Society.—The fifth annual meeting of this society will be held at the New York Academy of Medicine, New York City, June 2 to 4. An interesting program has been prepared, including a symposium on the recent advances in special therapeutics.

Filipinos Bring Trachoma.—Among 78 Filipinos who have come to the United States for the Filipino village at the St. Louis Exposition, 19 have trachoma. Since the Supreme Court has decided that the Philippines are a part of the United States, the application of immigration laws and deportation are said to be out of the question.

Progress of Ratification in New York.—At a meeting of the joint committee of conference held at the New York Academy of Medicine, May 6, 1904, the following resolutions were passed:

Resolved, That the president and the secretary of the Joint Committee of Conference be authorized and directed to make a certificate provided for in the tenth paragraph of the agreement, and the counsel of the committee be directed to proceed with diligence to obtain a final order for the consolidation of the corporations, pursuant to the terms of the agreement, and that the form of the certificate to be made by the chairman and the secretary, be in the form of the draft certificate submitted to this committee, which is as follows:

Supreme Court, New York County.

In the matter of the application of the Medical Society of the State of New York and the New York State Medical Association, for an order consolidating the said corporations, pursuant to the Act, Chapter 1, of the Laws of 1904:

This is to certify that the Joint Committee of Conference mentioned in the agreement for the consolidation of the Medical Society of the State of New York and the New York State Medical Association, which agreement was unanimously adopted by the Medical Society of the State of New York, at its annual meeting at Albany, Jan. 26, 1904, and by the New York State Medical Association at a special meeting of the association held in New York, March 21, 1904, has ordered the submission of said agreement or of any questions in connection therewith, to the county medical societies or associations referred to in said agreement, and that the conditions precedent to an application to the court for an order consolidating the Medical Society of the State of New York and the New York State Medical Association have been fully complied with, and this certificate is made pursuant to the tenth paragraph of said agreement.

Thirty out of 35 county associations have ratified; 1, Onondaga, has refused to ratify, 4 have not yet reported. The associations that have ratified represent a membership of 1711, and those that have not acted a membership of 42. The one refusing to ratify has 14 members. Ratifications have been received from 47 out of the 51 county societies; 4 have not yet acted. Those which have ratified represent a membership of 5,569, those which have not yet acted a membership of 164. According to the agreement, article 10 declares that:

> Whenever the chairman and secretary of the Joint Committee of Conference shall certify that the conditions precedent to an application to the court have been fully complied with, the presidents of the respective corporations shall, and they are hereby authorized and required in the name and behalf of their respective corporations to petition the Supreme Court for an order to consolidate in accordance with the terms thereof.

Therefore all county associations and societies that have not ratified will be asked to appear before the court at a specified date, appointed by the court, and show cause why the consolidation should not be completed according to the terms of the agreement, despite their failure to ratify.

FOREIGN.

Russians Studying Japanese.—The St. Petersburg Medico-Military Academy has opened courses in the Japanese language for physicians and students.

nfant Mortality in Australia.—A decreased birth-rate and increased infant mortality is reported from all of the ates of Australia and New Zealand.

Legacy for History of Medicine.—Professor Puschmann of Vienna, left a legacy of more than $125,000 to the University of Leipsic, the income of which is to be applied to promote the study of the history of medicine. He was at one time privat docent of the history of medicine at Leipsic.

Medical Journal Wins Suit.—A general practitioner in Berlin, Dr. Wolf Becher, took exceptions to an article published in the *Berliner klinische Wochenschrift* last year, and sued the proprietor of the journal, Prof. C. A. Ewald, for damages, claiming that he had been defamed. The article in question was written by Dr. Ritter, the subject being "Sanatoria for Children." The suit came up for trial last month, but was dismissed, the plaintiff being assessed the costs.

The Roentgen Decennial.—As already announced, the tenth anniversary of the discovery of the Röntgen rays will be celebrated next year at Berlin by a congress and exposition of Röntgenology, to be held April 30 to May 3, 1905. The committee of organization includes Eberlein, Immelmann and Cowl of Berlin, with Albers-Schönberg of Hamburg and Rieder of Munich. Professor Röntgen will be the guest of honor and von Bergmann will preside.

The Medical Insurance Company in Belgium.—We recently referred to the accident insurance company founded and conducted by physicians in Belgium. The annual meeting was held April 17, and out of the total 14,000 stockholders 6,085 were present in person or by proxy. Although organized only three years ago, the income last year was $25,000. A dividend of 5 per cent. could have been declared, but it was voted to set the sum aside for future contingencies when the new law on accident insurance goes into effect. Dr. L. Beco is president of the company, and the *Gazette Médicale Belge* of Liège has been its mouthpiece. The details of the annual meeting are given in the issue of April 21.

LONDON LETTER.

Central African Natives in the Transvaal.

The report of the health of the Central African natives imported to work the Transvaal mines is far from satisfactory. Three batches have been imported, as follows: 385 in June last, 345 in August and 88 in September. The total mortality was very high, nearly 82 per 1,000. The heaviest mortality occurred in the first batch, in which influenza broke out soon after its arrival. About 20 died from it in 6 weeks. A great mistake appears to have been made in bringing these natives of hot, low-lying regions to the high plateau of the Transvaal in the middle of winter. They should have been brought down during the hot season so as to enable them gradually to become acclimatized to the cold weather. Another source of illness was gross carelessness of the natives in respect to health and disregard of the most elementary precaution with regard to change of temperature.

The Port of London.

The annual report of the health officer for the port of London shows the immense amount of sanitary work involved in the shipping of the world's metropolis; 35,485 visits of inspection to vessels in the river and docks were made, and 3,133 ships required cleansing. The total number of vessels medically inspected at Gravesend was 2,552, which was higher than any number in the preceding five years. At Sheerness 342 ships were inspected; 157 cases of infectious disease were reported and 103 patients were removed to the Port Sanitary Hospital, of whom 3 were suffering from suspected plague, 11 from smallpox, 55 from typhoid fever, and 13 from "continued fever." The increased diffusion of plague throughout the world, the outbreaks of yellow fever in Mexico, Brazil, and elsewhere, and the existence of cholera in Syria and Palestine caused every precaution against the importation of these diseases to be taken. In order to enable the port sanitary authority to deal with outbreaks of typhoid fever due to shell fish polluted by sewage its jurisdiction will have to be considerably extended so as to include the estuaries in which the most famous oyster layings are situated. During the year 955 tons of food were seized and condemned. The imports of frozen mutton and lamb showed an increase of 960,000 carcasses.

The Plague.

In Cape Colony for the week ending March 26 no fresh cases of plague were found in man, but infected rats were discovered at Port Elizabeth and East London. In the Transvaal the number of reported cases up to April 9 was 154, of which 18 occurred in Europeans. The deaths amounted to 72, of which 7 were in Europeans. Up to April 16 only 4 more cases were reported.

Death of Sir Henry Thompson.

One who occupied a foremost position both in the profession and in the social life of the metropolis in the last part of the nineteenth century has passed away. Sir Henry Thompson (see notice of death, The Journal, April 30, p. 1154) was at once a great surgeon, a talented artist, a successful novelist, an authority on dietetics, a bon vivant, and the most prominent advocate of cremation in the country. He was indeed one of the most brilliant and versatile men that has ever adorned the profession. Born in 1820 he entered University College as a medical student in 1848, where he gained many honors. He graduated at the University of London in 1851, taking the gold medal in surgery. He became a fellow of the Royal College of Surgeons in 1853, having previously been awarded the Jacksonian prize of 1852 for his essay on "The Pathology and Treatment of Stricture of the Urethra." In 1860 he again successfully competed for the Jacksonian prize, the subject being "The Healthy and Morbid Anatomy of the Prostate Gland." In 1853 he was appointed assistant-surgeon to University College Hospital, in 1863 full surgeon, and in 1866 professor of clinical surgery. He proved a most successful teacher and operator. As indicated by his prize essays he devoted special attention to genito-urinary surgery from the beginning of his career. He assiduously studied under the great masters of other schools, and particularly came under the influence of the French surgeon, Civiale, who may be said to have first shown the possibility of lithotrity. Thompson soon became the foremost authority on genito-urinary surgery in this country, greatly improving instruments and laying down with great precision the rules for this specialty, of which he was the pioneer. These he embodied in his principal work, "Diseases of the Urinary Organs," which was published in 1868. It soon became a classic, and ran through eight editions, and was translated into French, German, Italian, Spanish, and Russian. A supplementary work, "Practical Lithotomy and Lithototry," achieved equal success. In 1863 he scored his greatest success by successfully operating on the king of the Belgians. The famous Civiale had previously discovered and crushed a stone in the bladder. After some relief the symptoms returned and many operations were performed without permanent success. The king endured great suffering, which he thought was due to a fragment of stone impacted in the neck of the bladder. At last he determined to seek the aid of English surgery, but he was so sceptical of the value of surgery that when Thompson was summoned he refused to submit to exploration of the bladder. The English surgeon, in the presence of his Belgian colleagues told the king that he was convinced that there must be a stone in the bladder, and that if he were not allowed to make a complete examination, and to act according to the condition found he must ask permission to be allowed to retire from the case. The king was very angry and dismissed all the physicians from the room. But the Belgians thoroughly approved of Thompson's course, Dr. Koepel exclaiming as they passed out "Vous avez bien parlé at bien fait." On the following day the king consented to an operation, which was completely successful. Thompson received a fee of $15,000 and various honors. The incident might have aroused some feeling of jealousy in Civiale, but Thompson, with admirable courtesy and tact, wrote him a letter describing the case, and attributing his success to the benefit he had derived from Civiale's teaching. The French surgeon returned the compliment by recommending Thompson's work on the prostate to the Académie de Médecine for the Prix d' Argenteuil, given for the best work on urinary surgery, with the result that it was awarded to him. His operation for stone on Napoleon III when in exile in England was not so successful, but this was not his fault because the king for political reasons deferred the operation too long. Fatal uremia followed lithotory. Sir Henry Thompson contributed largely to the medical journals, societies and surgical text-books. In "Holmes' System of Surgery" he wrote the section on the "Surgery of the Urinary Organs." Outside his specialty he took the greatest interest in and contributed to the literature of many topics. His indeed was a strenuous life. He wrote on such diverse subjects as "Moderate Drinking," "Cremation and Disposal of the Dead," "Diet in Its Relation to Age and Activity," and "An Attempt to Estimate the True Value of Prayer for the Sick," which aroused a theological storm. He was master of a graceful and trenchant style, and his writings were always effective and widely read. His two novels "Charlie Kingston's Aunt" and "All But," though not sufficient to form the groundwork of a literary reputation were most successful and pleased the public. The former ran through 15 editions in a short time. It was founded on the fate of a lady, who when away from home was suddenly deprived of all memory of her name, residence or identity. The opening scene was laid in the dissecting room of the University College Hospital. As an artist his position was much higher. He no doubt inherited his talent from his maternal grandfather, who was a distinguished artist. He was seldom without a pocketbook in which he would make pictorial memoranda of events whether witnessed in the wards or streets. After studying under Elmore and Alma-Tadema he became a regular exhibitor at the Royal Academy. His academy pictures "The à la Russe" and "Old Blue, Still Life" were hung in the Paris salon. Since 1874 he was president of the cremation society, and with his pen did much to help the movement both in England and on the Continent. As a host his reputation was unique; he reduced entertaining to a fine art. He established his famous "octaves"—dinners of 8 courses, for 8 people, at 8 o'clock. The main idea was that the guests should not exceed a number which seated round an oval table could all unite in the discussion of a single topic which might arise. The food was exquisite in kind, perfectly cooked and perfectly served, and the guests were chosen and seated with due reference to tastes and topics. These dinners were continued for 30 years, and at them met nearly every one of eminence in science, public life, art, letters, law and medicine.

The Treatment of Sewage.

The transmission of typhoid fever by shellfish taken from sewage-contaminated waters has been pointed out more than once recently in The Journal. The commission appointed to inquire into the methods of treating and disposing of sewage have now issued a third volume of their fourth report. a copiously illustrated blue-book of 316 pages, which is entirely devoted to reports by Dr. Houston on bacteriologic investigations, with special reference to the contamination of shellfish. The following conclusions are drawn "on a broad and common-sense view of the whole investigation": 1. That a water, which from the bacteriologist's point of view would be considered very impure, may after filtration, although still containing an appreciable number of bacteria seemingly of intestinal origin, be used for domestic purposes without definite or detectable harm. 2. That the water of a tidal river grossly polluted in its lower estuarial reaches may, after a flow of some twenty-five miles, become so far purified by sedimentation, dilution, and the operation presumably of bactericidal agencies, as to become seemingly as little objectionable, or in some respects less objectionable, bacteriologically, than certain public water supplies. 3. That the deposition in the sea of chemically precipitated sludge in enormous quantities, if carried out under proper conditions, need not result in the production of serious pollution. The first conclusion is somewhat modified by an appended note stating that it is not implied that impure waters after careful filtration are necessarily safe. The results are not very definite, but are a contribution toward the solution of the questions raised. They show the danger of hastily condemning waters without a wider knowledge of comparative bacteriology, and of the correlation of bacteriology and epidemiology than is available at present.

Malaria in the Malay Peninsula: Success of the Anti-Mosquito Campaign.

The state surgeon of Selangor, one of the federated states of the Malay Peninsula, has described a severe outbreak of malignant malarial fever in the malarial district of Klang. A new port was constructed and opened under the name of Port Swettenham in September, 1901. Almost immediately malaria increased to an alarming extent. Almost the whole of the laborers were attacked, and many severe cases occurred among the ships' crews. Of 133 persons living in government quarters 80 were attacked between September 15 and November 26. Of 27 temporary shop houses with 127 inmates no fewer than 78 persons living in 25 of the shops contracted the disease during the same period. Blocked drains and shallow pools were found along the whole sea front and by the side of the road, containing large numbers of anopheles and culex larvæ. A drainage scheme was carried out and all pools containing larvæ were regularly sprinkled with crude kerosene oil. The majority of the coolies working at the port were given a daily dose of 10 grains of quinin. By December 10 marked improvement was reported. During 1901, 52 deaths from malarial fever occurred in the district hospital; in 1902 there were only 9 deaths. In the town of Klang and the port of Swettenham, where extensive sanitary works were carried out, malarial fever has decreased by 67 per cent., whereas in the remainder of the Klang district which has not been dealt with in any way malarial fever has increased by 3.5 per cent.

Correspondence.

Sleeping Car Improvement.

Memphis, Tenn., May 2, 1904.

To the Editor:—Now that the Pullman Company intends making sanitary changes in their sleeping cars, might this not be an opportune time to advocate some change in the car structure, whereby sick and injured persons can be moved without so much inconvenience? At times patients have to undergo torture in being squeezed through the narrow and tortuous entrance of a sleeper, or else have to be hoisted up to and through a narrow window. This at times frightens a patient, and is not entirely without risk. I believe that with slight changes in the construction of a sleeper, all of this could be avoided, and would certainly add to the comfort and safety of patients.

Alfred Moore.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

YOHIMBIN.

Sandersville, Miss., May 3, 1904.

To the Editor:—I wish to secure some yohimbin hydrochlorate for use in practice. Can you inform me what it is and where it may be obtained? Have not found it listed by any pharmaceutic house. Any information concerning it will be appreciated.

M. D. Ethridge.

Answer.—Yohimbin is the alkaloid of the yohimbehe bark—the bark of a tree growing in the Kameroons, in German Africa—belonging to the natural order *Apocynacce,* species *tabcnacmontana.* The alkaloid, supposed to be the active principle, is obtained by a process patented in England by Spiegel of Berlin. The alkaloid occurs in needles, is almost insoluble in water, melting at 234 degrees C., and has the chemical composition $C_{22}H_{30}N_2O_4$ or $C_{23}H_{32}N_2O_4$. The hydrochlorid has been used in impotency in dose of 0.005 (five milligrams). Manufacturers: Riedel in Berlin and Merck in Darmstadt, Germany; factors for the United States, Lehn & Fink, New York City. Since its first introduction, about two years ago, it has been given little mention in the medical literature.

Marriages.

William Blender, M.D., to Miss Meda Klotz of Columbus Junction, Iowa.

John Houff, M.D., to Miss Elizabeth May Nichols, both of Baltimore, April 30.

Oswin W. Berry, M.D., Bally, Pa., to Miss Amy Latshaw of Barto, Pa., April 29.

Calvin B. Stark, M.D., Shiloh, Ark., to Miss Leila Roper of Rosebud, Texas, April 12.

Emil T. Cherry, M.D., Altoona, Pa., to Miss Mary R. Eddy, of Ashland, Ohio, April 26.

D. W. Wright, M.D., Langley, S. C., to Miss Nannie Keister, at Roanoke, Va., April 27.

Charles Huff Waters, M.D., to Miss Meta L. Thorn, both of Trenton, N. J., April 21.

Carl Victor Malmgren, M.D., to Miss Abbie Smith, both of Virginia, Minn., April 21.

Edward F. Dowd, M.D., to Miss B. Gertrude Connelly, both of Waltham, Mass., April 27.

Lewis Jefferson Daniels, M.D., to Miss Anna Estelle Jung, both of Milwaukee, April 20.

Charles Herbert Phifer, M.D., to Miss Eleanor Lois Grover, both of Chicago, May 4.

Sylvester James Deehan, M.D., to Miss Gena Gallagher, both of Philadelphia, April 27.

Charles A. George, M.D., Berryville. Ark., to Miss Georgia Robinson, of Kansas City, Mo.

William J. Frick, M.D., to Miss Katharine J. Menet, both of Kansas City, Mo., April 28.

John M. Anderson, M.D., to Miss Minnie La Belle Jones, both of Montgomery, Ala., April 30.

Harper Ansie Wright, M.D., Calvin, Pa., to Miss Bertye Josephine Maier of Baltimore, February 9.

William Inscho Dean, M.D., Mayville, N. Y., to Miss Margaret Moran of Lyons, N. Y., April 27.

Arthur C. Lewis, M.D., Fall River, Mass., to Miss Fanny Lynch of South Somerset, Mass., April 27.

Alfred G. Bull, M.D., Wilkesbarre, Pa., to Miss Mary Eleanor McDonald of Philadelphia, April 27.

Robert Gordon Norfleet, M.D., to Miss Nancy Elzey Woolford, both of Princess Anne, Md., April 27.

William Clark Hienen, M.D., Whittemore, Iowa, to Miss Claribel Cook Leonard of Newton, Iowa, May 3.

Robert Moore Blanchard, M.D., assistant surgeon U. S. Army, to Miss Mary Wallace Dewitt, daughter of Brigadier-General Calvin Dewitt, M.D., U. S. Army, at Washington, *April 26.*

Deaths.

William Barton Hopkins, M.D. University of Pennsylvania, 1874, of Philadelphia, died of uremia, after a few days' illness, May 4, aged 50. He was the grandson of Dr. Samuel Hopkins, and the grand-nephew of that eminent physician, Dr. John Rhea Barton. After graduation he served twenty months as resident physician in the Pennsylvania Hospital. He had been an active member of the College of Physicians since 1879. Dr. Hopkins was made dispensary surgeon to Episcopal Hospital in 1879 and regular surgeon in 1884. He was made surgeon to the Pennsylvania Hospital in 1895. He was also visiting surgeon to the Orthopedic Hospital. Dr. Hopkins contributed many valuable and practical papers to medical literature. The two most prominent works were his book on "The Roller Bandage" and his recent book, "Clinical Treatise on Fractures."

Luther D. Jacobs, M.D. University of Pennsylvania, Philadelphia, 1866, a member of the American Medical Association; one of the most prominent and respected physicians of Emporia, Kan.; local surgeon of the Santa Fe system; member of the National Association of Railway Surgeons and the Kansas Medical Society; ex-president of the Santa Fe Railway Medical and Surgical Society; president of the Lyon County Medical Society, and fellow of the American Academy of Medicine, died in a hospital in Chicago, April 28, after an operation for disease of the stomach.

Almon Clarke, M.D. University of Michigan, Ann Arbor, 1862, formerly chief surgeon of the National Soldiers' Home, Milwaukee, president of the Wisconsin Medical Society in 1894, and professor of physical diagnosis in Milwaukee Medical College, a surgeon in the Vermont Volunteers during the Civil War, died at his new home in Pensacola, Fla., May 1, after a short illness, aged 63.

Edward Reed Wheeler, M.D. Bellevue Hospital Medical College, New York City, 1864, of Spencer, Mass., surgeon during the Civil War; a member of the American Medical Association; founder of the Spencer Free Dispensary; formerly president of the Worcester County Medical Society, and a councilor of the Massachusetts Medical Society, died suddenly from angina pectoris at Winthrop Beach, Mass., April 30, aged 64.

Giles S. Mitchell, M.D. Medical College of Ohio, Cincinnati, 1875, a member of the American Medical Association; professor of gynecology in the Cincinnati College of Medicine and Surgery; ex-president of the Cincinnati Academy of Medicine, and the Cincinnati Obstetrical Society; surgeon to St. Mary's Hospital, died suddenly at his home in Cincinnati, May 5.

John McQ. Stansill, M.D. University of Maryland School of Medicine, Baltimore, 1872, a member of the American Medical Association and the Medical Society of the State of North Carolina; surgeon of the Seaboard Air-Line Railway, died suddenly from heart disease while attending a meeting of school trustees at Rockingham, N. C., April 25, aged 55.

John R. Hawkins, M.D. Rush Medical College, Chicago, 1900, a member of the American Medical Association, coroner of Minnehaha County, S. D., prominent professionally and in National Guard circles, died from liver disease at his home in Sioux Falls, May 3, after a prolonged illness.

Orissa W. Gould, M.D. Woman's Medical College of the New York Infirmary, New York City, 1892, noted for her charitable and philanthropic work among the poor of the East Side, died at the New York Hospital, May 3, from cerebrospinal fever, after an illness of three days, aged 43.

James Griffin Conly, M.D. Rush Medical College, Chicago, 1862, the oldest practitioner in South Dakota, died at his home in Elk Point, May 8, from pneumonia, aged 66. He served throughout the Civil War as surgeon of the Third Wisconsin Volunteer Infantry.

Melvin W. Caster, M.D. Medical College of Ohio, Cincinnati, 1877, formerly coroner and health officer of St. Louis County, Mo., and for the last four years postmaster of Clayton, died at his home in that place, April 30, from pneumonia, after a short illness, aged 73.

Benjamin F. Moulton, M.D. Harvard University Medical School, Boston, 1867, who, while still a student, served as surgeon during the Civil War; a member of the Essex North District Medical Society, died at his home in Lawrence, Mass., *May 3, aged 59.*

Ole S. Merager, M.D. Sioux City College of Medicine, 1899, a member of the American Medical Association, and of the Seventh District Medical Society of South Dakota, died recently at his home in Sioux Falls from pneumonia.

Augustus F. W. Reimer, M.D. University of Göttingen, Germany, 1860, some-time coroner of Queen's County, N. Y., died at his home in College Point, N. Y., April 29, from Bright's disease, after an illness of six weeks, aged 66.

Robert M. Price, M.D. Baltimore Medical College, 1861, who retired from practice in 1884; state fire marshal of Maryland died at his home in Centerville, April 30, from pneumonia, after an illness of six days, aged 62.

Henry C. Whitehead, M.D. Vanderbilt University, Nashville, 1893, for several years city physician of Fort Worth, Texas, died at his home in that city, from consumption, April 22, after a prolonged illness, aged 43.

Emma L. McCollum Clawson, M.D. University of Michigan, Ann Arbor, 1891, of Battle Creek, Mich., a member of the American Medical Association, died April 24, from pneumonia, at Los Angeles, Cal., aged 39.

John Antoine Gibbons, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1883, demonstrator of anatomy in that institution for three years, died from inanition at his home in Keokuk, May 1, aged 41.

Marshall O. Butterfield, M.D. Medical College of Ohio, Cincinnati, 1880, of Ross, Ohio, committed suicide at the home of his brother, near Venice, Ohio, by shooting himself in the head, May 1, aged 51.

Thomas B. Saulsbury, M.D. College of Physicians and Surgeons, Baltimore, 1882, of Towson, Md., died at the Maryland General Hospital, Baltimore, May 1, after an illness of two years, aged 53.

John Parker Holmes, M.D. Harvard University Medical School, Boston, 1888, an ophthalmologist of Boston, died at his home in West Newton, Mass., May 1, after an illness of eight weeks, aged 43.

John B. Blanton, M.D. Medical College of Virginia, Richmond, 1860, regimental surgeon in the confederate service, died at his home in Chico, Texas, April 25, after a prolonged illness, aged 65.

Elias B. Herr, M.D. New York University, 1854, during 1869 and 1870 a member of the Pennsylvania legislature, died at his home in Lancaster, Pa., April 28, from organic heart disease, aged 70.

Walton Fuqua, M.D. Medical College of Virginia, Richmond, 1896, a member of the Medical Society of Virginia, died at his home in Stewartsville, Va., April 26, after a short illness, aged 32.

Louis Bedford Welch, M.D. University of Maryland School of Medicine, Baltimore, 1879, of Shireock, Pa., died, April 27, at the family residence in West Elizabeth, Pa., aged 68.

Roberts Bartholow, M.D. University of Maryland, Baltimore, 1852, died at his home in Philadelphia May 10. An extended notice will appear in the next issue of The Journal.

William J. Anderson, M.D. Faculty of Medicine of Queen's University, Kingston, Ont., 1861, died at his home in Smith's Falls, Ont., February 19, after a lingering illness.

Thomas John Chew, M.D. University of Maryland School of Medicine, Baltimore, 1868, died suddenly from apoplexy at his home in Washington, D. C., May 2, aged 57.

B. Frank Jones, M.D. Jefferson Medical College, Philadelphia, 1888, died at his home in Idaho Falls, Idaho, February 3, from septicemia, after an illness of three months.

Adelaide Lorena Ainsworth, M.D. State University of Iowa College of Medicine, Iowa City, 1903, died recently from typhoid fever at her home in Fort Dodge, Iowa.

Herman L. Staudinger, M.D. Humboldt Medical College, St. Louis, 1867, died suddenly at his home in St. Louis, April 24, from disease of the stomach, aged 63.

Grant H. Richtmyer, M.D. University of Vermont, Burlington, 1890, died at his home in New York City, April 21, from pneumonia, after a short illness, aged 39.

Elijah Tennant, M.D. Castleton (Vt.) Medical College, 1858, of Boone, Iowa, died at the Eleanor Moore Hospital in that city, April 26, from pneumonia, aged 67.

Daniel W. Shoemaker, M.D. Pennsylvania, 1881, died at his home in Philadelphia, from pneumonia, April 27, after an illness of one week, aged 44.

William T. Gerisch, M.D. St. Louis Medical College, 1880, Omaha, died suddenly from heart disease at his home in Omaha, April 29, aged 65.

Louis Drescher, M.D. Bellevue Hospital Medical College, New York, a retired physician of Newark, died at his home in that city, April 27, aged 84.

Duncan Fraser, M.D. Toronto University Medical Faculty, 1874, died recently at his home in Lakefield, Ont., after a short illness, aged 57.

Joseph P. Chartrand, M.D. University of the Victoria College, Cobourg, Ont.. died at his home in Quebec, April 25, from spinal meningitis, aged 43.

Elizabeth Schmidt, M.D. Central College of Physicians and Surgeons, Indianapolis, 1880, died at her home in that city, March 4, aged 77.

Allen H. Farquhar, M.D. Ohio, 1868, died at his home in Ridgeville, Ind., April 21, from cancer of the stomach, after a prolonged illness.

William K. Wheat, M.D. Philadelphia College of Medicine and Surgery, 1851, retired, died at his home in Caro, Mich., May 1, aged 74.

William G. Christoe, M.D. University of the Victoria College, Cobourg, Ont., 1866, died recently at his home in Flesherton, Ont., aged 79.

William S. Balken, M.D. College of Physicians and Surgeons, New York, 1886, died at his home in Brooklyn, N. Y., March 23, aged 42.

T. Lloyd Carey, M.D. Chicago Medical College, 1868, died suddenly at his home in Chicago, May 2, from heart disease, aged 60.

William J. Gillespie, M.D. Jefferson Medical College, Philadelphia, 1890, died at his home in Philadelphia, March 14, aged 35.

William B. Rimes, M.D. Medical College of Georgia, Augusta, 1891, of Pembroke, Ga., died in Savannah, Ga., March 21, aged 36.

Thomas A. Mullryne, M.D., of Coffee Bluff, Ga., was drowned in Ossabaw Sound, Ga., by the capsizing of a sailboat, April 28.

Rufus K. Hinton, M.D. Jefferson Medical College, Philadelphia, 1852, died at his home in Philadelphia, April 4, aged 74.

Francois Muguet, M.D. Ecole de Médecine, Paris, France, 1843, died at his home in Louisville, Ky., March 18, aged 84.

William Merritt, M.D. University of Virginia, Charlottesville, 1850, died at his home in Roxboro, N. C., May 1, aged 79.

Charles H. Winslow, M.D., retired, of New York City, died from paralysis at New Rochelle, N. Y., April 30, aged 72.

Charles H. Crawford, M.D. Albany (N. Y.) Medical College, 1881, died suddenly at his home in Chicago, April 28.

Henry P. McDowell, M.D. Medical College of Indiana, Indianapolis, 1882, died at his home in Peru, Ind., April 24.

M. Frank Terry, M.D. Pennsylvania, 1864, died at his home in Seattle, Wash., April 23, from dropsy, aged 64.

W. R. Hurst, M.D. Medical College of Georgia, Augusta, 1854, died at his home in Decatur, Ga., May 2, aged 76.

Henry T. Murphy, M.D. Rush Medical College, Chicago, 1890, of Chicago, died recently and was buried April 18.

Eli Swarts, M.D. Ohio, 1878, died at his home in Kansas City, Kan., April 28, from erysipelas, aged 68.

William C. Rosamond, M.D. Alabama, some-time state senator, died at his home in Jasper, Ala., April 23.

James L. Adams, M.D., died at his home in Dallas, Texas, April 30, after a prolonged illness, aged 72.

Thad L. Johnson, M.D. Ohio, 1891, died at his home in Pomona, Cal., March 9, after a long illness.

W. S. Evans, M.D., a practitioner for forty years, died at his home in Marion, Ill., April 26, aged 95.

J. T. McKey, M.D., of Atlanta, Ga., died at Grady Hospital in that city, April 29, after a long illness.

A. J. Carter, M.D., died at his home in Lyndon Center, Vt., April 20, from Bright's disease, aged 62.

E. Edgar Maryott, M.D. Albany (N. Y.) Medical College, 1882, of Coxsackie, N. Y., died recently.

Algernon S. Holderness, M.D. Arkansas, died at his home in Fordyce, Ark., April 29, aged 71.

Neil Q. Pope, M.D., died, April 27, at his home in Atlanta, Ga., after a long illness, aged 45.

Horace H. McDonald, M.D., died at his home in Conyers, Ga., May 3, aged 71.

Deaths Abroad.

V. A. Ratimoff, M.D., professor of surgery at St. Petersburg for twelve years, died in the Crimea in March, after three years of illness, aged 53. He was the successor of Pirogoff and was frequently a delegate from Russia to international medical congresses, and a contributor to medical literature.

Sir Philip Crampton Smyly, M.D., F.R.C.S.I., 1863, ex-president of the Royal College of Surgeons in Ireland, honorary surgeon to the king in Ireland, senior surgeon, Meath Hospital, Dublin, died suddenly at his home in Dublin, from cerebral hemorrhage, April 7, aged 65.

Karl von Koch, M.D., died at Stuttgart, February 25, aged 75. He had been at the head of official medical affairs in Wurtemberg for many years, and inaugurated the official medical reports for the kingdom, editing the first issues.

B. T. Thierfelder, M.D., ex-professor of medicine at Rostock and author of numerous works on infectious diseases and on affections of the stomach and liver, died at Rostock, March 17, aged 79.

Augustin Reyes, M.D., one of the founders and until recently president of the present national board of health of Mexico, died at Mexico City, Dec. 18, 1903, aged 74.

F. deP. Chacon, M.D., one of the most prominent physicians and professors of Mexico, died March 20.

Jean Roger, M.D., inspector general of the French quarantine service, died recently.

Book Notices.

POLK'S MEDICAL REGISTER AND DIRECTORY OF NORTH AMERICA, Comprising List of Physicians and Surgeons, Arranged by Location, Giving Postoffice Address with Population, the School Practiced, Date and College of Graduation, All the Existing and Extinct Medical Colleges in the United States and Canada, with Locations, Officers, Number of Professors, Lecturers, Demonstrators, etc., the Various Medical Societies, Penal Reformatory and Charitable State Institutions, Hospitals, Sanitariums, Dispensaries, Asylums and Other Medical Institutions, Boards of Health, Boards of Medical Examiners, Health Officers at Principal Points, the Laws of Registration and Other Laws Relating to the Profession, Medical Journals, with Names of Editors, Frequency of Publication and Subscription Rates, Medical Libraries, Therapeutic Classification of American Health Resorts, Mineral Springs, Official List of Officers of the Medical Departments of the U. S. Army, Navy and Marine-Hospital Service, Roster of Examining Surgeons of the U. S., Pension Department, a Descriptive Sketch of each State, Territory and Province, Embodying such Matter as Location, Boundary, Extent in Miles and Acres, Latitude and Longitude, Statistics Relating to Climate, Temperature, Rate of Mortality, etc., Full Particulars of All National Associations and Societies Relating to Medicine and Surgery, and an Index to the Physicians of the United States. Arranged Alphabetically with the Number of the Page and the Column on Which the Name Appears. Eighth Revised Edition. 1904. Cloth. Pp. 3,076. Price, $10. Detroit, Baltimore, Chicago: R. L. Polk & Co.

The eighth edition of this work is now being distributed. The new edition embraces the entire North American continent, and considering the vast territory it covers and the data for so many thousands of practitioners, it is fairly accurate and complete. Many new and valuable features are noted and the publishers seem to have covered the ground so thoroughly that all information to be expected in the field it occupies has been anticipated and fully supplied. The register has grown to be a voluminous publication and it is noted that this edition comprises 3,074 closely printed pages. Its exhaustive data certainly brings the medical men of the land in closer touch than could be the case otherwise. It is a roster of the profession in the northern half of our hemisphere and it is probably the largest professional directory in the world.

DIRECTIONS FOR LABORATORY WORK IN PHYSIOLOGICAL CHEMISTRY. By Holmes C. Jackson, Ph.D., Assistant Professor of Physiologic Chemistry in the University and Bellevue Hospital Medical College. Second Edition Rewritten and Enlarged. First Thousand. Cloth. Pp. 148. Price, $1.25. New York: John Wiley & Sons. 1903.

The original edition of this work appeared last year and the author has already revised and brought it up to date in the present volume. For a student's laboratory manual it would seem to meet the requirements in the department of physiologic chemistry.

MANUAL OF CLINICAL MICROSCOPY AND CHEMISTRY, Prepared for the Use of Students and Practitioners of Medicine. By Dr. Hermann Lenhartz, Professor of Medicine and Director of Hospital at Hamburg, etc. Authorized Translation from the Fourth and Last German Edition, with Notes and Additions, by Henry T. Brooks, M.D., Professor of Histology and Pathology at the New York Post-Graduate Medical School and Hospital. With 148 Illustrations in the Text and 9 Colored Plates. Pp. xxxii-412. Cloth. Price, $3.00 net. Philadelphia: F. A. Davis Company.

Dr. Brooks has done a service by translating this German work, which has rapidly passed through three editions in its own country, and by adding to it many valuable annotations. He has also been able to insert the additions furnished by the author from the fourth German edition soon to be published. The book may be, therefore, considered well up to date and a very useful handbook in clinical microscopic diagnosis. It covers a wider range than some of the works of its class, including not only the ordinary urinary, blood and other examinations, but also the detection of parasites, macroscopically as well as microscopically.

WHAT SHALL WE EAT? The Food Question from the Standpoint of Health, Strength and Economy. Containing Numerous Tables, Showing the Constituent Elements of Over Three Hundred Food Products, and Their Relations, Cost and Nutritious Values, Time of Digestion, etc., Indicating Best Foods for All Classes and Conditions. By Alfred Andrews. Pp. 116. Price, 75 cents. New York: Health Culture Co.

The title explains the book. It is not supposed to be a medical treatise, but its elaborate tables, comparative statements, diagrams and charts will be of great value to any physician or nurse or other person interested in dietetics. It can be recommended also for popular use in the household.

CHEMISTRY, INORGANIC AND ORGANIC, WITH EXPERIMENTS. By Charles Loudon Bloxam. Ninth Edition, Rewritten and Revised By John Millar Thomson, LL.D., F. R. S., Professor of Chemistry, King's College, London; and Arthur G. Bloxam, F.I.C., Consulting Chemist and Chartered Patent Agent. Cloth. Pp. 871. Price, $6.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

This English work, long before the public, is intended for a student's manual of chemistry and in its present form appears to be very satisfactory. Some little changes have been made in the order of the contents and some new illustrations have been added. Otherwise, aside from additions required by the progress of science, the work is not materially changed from the former editions. It is one of the better handy works for reference and study on the subject.

THE VALUE OF URETERIC MEATOSCOPY IN OBSCURE DISEASES OF THE KIDNEY. A Study in Clinical and Operative Surgery. By E. Hurry Fenwick, F.R.C.S., Surgeon to and a Lecturer on Clinical Surgery at the London Hospital. Cloth. Pp. 219. Price, $2.30 net. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

This work brings out a point in genito-urinary diagnosis that is probably not familiar to most practitioners—the value of the inspection of the ureteral orifice. The author has formulated certain rules for ureteric meatoscopy and gives examples of his experience with this method during ten years. It seems to us that the author has made a very good case for this method of examination. How far it can be substituted for the more elaborate examinations or other methods is beyond our province to state.

AIR, FOOD AND EXERCISE. An Essay on the Predisposing Causes of Disease. By A. Rabagliati, M.A., M.D., F.R.C.S. Edin., Honorary Gynecologist and Late Senior Honorary Surgeon, Bradford Royal Infirmary. Third Edition, Greatly Enlarged and Almost Entirely Rewritten. Cloth. Pp. 559. Price, $3.00 net. New York: Wm. Wood & Co. 1904.

The author of this bulky volume rather courts criticism in his preface to the work, noting the fact that since the former volume (noticed in THE JOURNAL, July 6, 1901), which was addressed to the medical profession, received a comparatively uncordial reception, he has written this work frankly for the public. It appears to us that it will receive a much less degree of attention from those to whom it is addressed than would be the case were it written more for the medical profession itself. Still, what the public can understand, physicians ought to. His ideas are well worth at least respectful consideration. The main motive of the work, as we see it, is to portray the evils of over-eating; the public certainly needs advice on this subject. The book is full of good points and while it may be that the author overestimates the rôle played by the systemic conditions due to nutritive excesses and defects, especially in their relations to infections, his ideas are such as will induce a certain amount of profitable thinking.

PEDIATRICS. Lea's Series of Medical Epitomes. A Manual for Students and Practitioners. By Henry Enos Tuley, A.B., M.D., Professor of Obstetrics in the Medical Department of Kentucky University, Louisville, Ky. Cloth. Pp. 266, with 33 Engravings. Price, $1.00 net. Philadelphia and New York: Lea Brothers & Co. 1903.

This is simply a handy epitome of the care and disorders of children and apparently meets a need, within its limitations. For a handy reference book or a condensed summary of the principal points it seems thorough and complete. Of course, it could not be substituted for the more thorough works on the subject.

THE MAN WHO PLEASES AND THE WOMAN WHO CHARMS. By John A. Cone. Cloth. Pp. 131. Price, 75 cents. New York: Hinds & Noble.

This is a delightful treatise on a practical subject. It is full of hints how to be agreeable, attractive and lovable, and how to awaken by one's presence happy impressions in another. The physician will be glad of its advice on tact, address, optimism, etc., not only in his social duties but in his professional life.

INFANT FEEDING IN ITS RELATION TO HEALTH AND DISEASE. A Modern Book on All Methods of Feeding. For Students, Practitioners and Nurses. By Louis Fischer, M.D., Visiting Physician to the Willard Parker and Riverside Hospitals of New York City. Third Edition, Thoroughly Revised and Largely Rewritten. Containing 54 Illustrations, with 24 Charts and Tables, Mostly Original. Cloth. Pp. 357. Price, $2.00 net. Philadelphia: F. A. Davis.

We have already noticed the preceding editions of this work. The book now comes out completely revised and greatly enlarged; it is in fact practically a new book, representing modern views. It contains a large number of practical formulas, and can be recommended to those who want an up-to-date work on the important subject of infant feeding.

AN INTRODUCTION TO VERTEBRATE EMBRYOLOGY. Based on the Study of the Frog and the Chick. By Albert Moore Reese, Ph. D. (Johns Hopkins), Associate Professor of Histology in Syracuse University and Lecturer on Histology and Embryology in the College of Medicine. With 84 Illustrations. Cloth. Pp. 291. Price, $1.40. New York and London: G. P. Putnam's Sons. The Knickerbocker Press. 1904.

While this is not a medical work, it is one with which the medical preparatory student ought to be acquainted. The needs of the medical student are largely considered in compiling the text. A certain amount of knowledge of comparative embryology ought to be an important preliminary requisite to the study of medicine. In this little handbook such information is very conveniently summarized.

A MANUAL OF MEDICINE. Edited by W. H. Allchin, M.D., Lond., F.R.C.P., F.R.S. Ed., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. V. Diseases of the Digestive System and of the Liver, Diseases of the Peritoneum and of the Vessels of the Abdomen, Diseases of the Kidneys, Diseases of the Ductless Glands. Cloth. Pp. 687. Price, $2.00. New York: The Macmillan Co. 1904.

The list of authors of this fifth volume includes such names as John Rose Bradford, J. Henry Bryant, William Hale White and other prominent English practitioners. The articles, as in the other volumes, are convenient condensed monographs of the different subjects. The work has its omissions, but they are few. There is a lack of reference to recent American work, such, for example, as that of Opie and of others on the pancreas, but this is not unusual with English works.

LA RACHITIDE E LE DEFORMITA DA ESSA PRODOTTE. By Dott. P. Mancini. Un vol. di pag. xxviii-300, con 116 inc. L. 4. Milano: Ulrico Hoepli. 1904.

This is another of the Hoepli manuals, and is a complete little compilation and description of rachitis, which in some forms is probably more frequent in this country than many practitioners have realized. The portions on the pathologic anatomy and on treatment are also commendably full, and for the pediatrist and orthopedist surgeon, the work is of value, even in the Italian language. The bibliography is extensive in its references to European writers, but, in omitting many other authorities, it is incomplete.

LE MALATTIE DEI PAESI CALDI LORO PROFILASSI ED IGIENE con un'appendice: *La vita nel Brasile.* By Dott. Carlo Muzio. Un vol. di pag. xi-560 con 154 inc. e 11. L. 7.50. Milano: Ulrico Hoepli. 1904.

With the world-wide expansion of commercial enterprise, especially in this country, the importance of tropical medicine is becoming more and more appreciated. The comparatively few text-books on the subject are none too many, even with the addition of this little volume. Dr. Muzio, the author and compiler of this work, is a physician of the Italian navy, and undoubtedly has had large opportunities for observing and studying the disorders of which he here treats. Not every one reads Italian readily, and yet it is a language of which a reading knowledge of medical matters is easily acquired. Every physician going to the tropics will do well to add this little treatise to his working library. In fact, it is not less voluminous in its way than Manson's work, though not so complete and elaborate as that of Scheube. We are sorry to see that the author, perhaps from patriotism, hurts the value of his work by still adhering to the theory of the etiologic relations of Sanarelli's bacillus in yellow fever and minimizing the importance of the researches that have exterminated the disease in Cuba. In this respect the work is behind the times, and not a safe guide.

Miscellany.

A MODERN PROFESSIONAL INSTANCE.

BY U. O. B. WINGATE, M.D., MILWAUKEE, WIS.

Dr. X was engrossed in writing notes for his lecture to his class of medical students; it was not his custom to see any one under such circumstances, as it was past his office hours. He fully understood his state of mind when thus engaged; it was difficult for him to grasp any new or foreign proposition at short notice. But a gentleman was announced from the waiting-room, with the statement that an old friend desired to see him on important matters; a man entered, well dressed, wearing gloves, and with his glasses dangling at the end of a long gold chain.

Stranger: How do you do, Doctor? I doubt if you remember me (extending his hand). You may recall the fact that I was presented to you by Dr. D of B——— at the World's Exposition at Chicago. I am Dr. P.

Dr. X: I do not recall the circumstance.

Stranger: No doubt it has escaped your memory; one can not remember so many persons, and that was some time ago. You know Dr. S and Dr. Y of Philadelphia, I presume?

Dr. X: Oh, yes; I know them well.

Stranger: I met Dr. Y a few days ago. He is much interested in the next session of the American Medical Association at Atlantic City. You expect to attend, Doctor, do you not?

Dr. X: I may, but it is too soon to say positively.

Stranger: I learn that Dr. T (naming a physician of Dr. X's city) has taken a position in the Navy. I would not suppose that he would like such a position.

Dr. X: It may seem strange, but I believe Dr. T likes the Navy better than civil practice.

Stranger: Doctor, I have called on a very unpleasant errand. I came to the city a few days ago and expected a draft to reach me here, but it has not yet arrived, and I need ten dollars very much. Can you, as a brother physician, let me have it? I must go to K——— to-night on a matter of business there, and will receive some money there, and whether the draft arrives or not, I will hand you back the loan tomorrow, as I shall come back here in the morning.

Dr. X: Certainly; I am glad to accommodate you.

Stranger: Thank you very much, Doctor. I shall not forget this kindness, and if you should not be in when I call in the morning I presume I may leave the money with your office boy, or with your servant who may open the door?

Dr. X: Certainly; that will be all right.

Stranger: Good day, Doctor; a thousand thanks. (Exit stranger.)

Dr. X (alone): Confound it! Will I ever learn anything? That fellow is a sharper; I never met him before, and probably will never see him nor my money again. Why will I continue to break my rule and let a person in when I can not defend myself nor my pocket-book? In the language of Spiegleburger, "Such a chackass vat I am!"

Another Instance—Perhaps the Same Individual.

WM. ALLEN PUSEY, M.D., CHICAGO.

About two weeks ago a man came in to see me who announced that he was a graduate from the same school and had the same specialty with me, and had come in to call on me simply to make my acquaintance. He was a dapper, well-dressed man, about forty years old, five feet six or seven inches in height and weighing probably 160 pounds. He looked rather like a foreigner, dark complexion, with dark hair and moustache, the latter charmingly waxed. He talked for a few minutes with apparent intimacy about some of the professors in my old school; said he was on his way back from Europe, and that his residence was in San Francisco, and then departed. There was so little apparent reason for his call, and he was so smooth in manner and appearance, that I wondered what could have been the motive of his call.

About two days later he came in again and asked to see me for just a moment. With very brief preliminary excuse he told me that he wanted to borrow $10 for twenty-four hours. As he did not get the money I should have forgotten the matter, but that in talking with Dr. Frank Andrews to-day I find that he tried the same scheme, with unessential variations in details, on him, and got $5 for twenty-four hours, which has not been returned. Apparently, therefore, he is going over the country making small levies on his brother alumni and brother specialists—doubtless from all schools and in all specialties.

I recite the experience with the hope that its publication may save some one from this impostor.

MEDICAL PRACTICE IN IRELAND.

The Unfortunate Condition of Many Practitioners Under Contract Practice in Ireland.

A special commissioner of the *British Medical Journal* gives, in the issue of March 26, the history and an account of the Irish poor law medical system—and a black picture it is.

It appears that this service, which has grown up since the famine of 1847, has become a system for sweating the medical profession, and that under the more recent Irish legislation it affords a strong suggestion of the worst political practices in this country. The honest physician who wishes to do his duty finds himself subject to the beck and call of a much larger number of superiors than was formerly the case, obliged to carry out an elaborate system of clerical accounts, beside attending each year four or five hundred dispensary cases for which he is to dispense all medicine and also attending to three or four hundred patients at their homes, making an average of probably 2,000 calls, ranging over a territory of from twenty to eighty square miles in extent; all this for a pittance of about $500 a year and what little extra he can obtain from the services to the Irish constabulary and lighthouse establishment and from acting as registrar of vital statistics for the district. As the *British Medical Journal* figures it out, these qualified medical men serve the public at an average of pay that the Irish constable is allowed for horse keep and servant, and the conditions are not improving. If he asks for more he is insulted. The newer and more democratic administration under the recent Irish laws is, if anything, worse than it was under the old landlord system. Of course, if the medical man chooses to neglect his work, as some do, to devote himself to side issues he may make it profitable. According to the commissioner's report, there are persons appointed for purely political reasons who are utterly unfit for such positions. This testimony comes not only from his own personal observations, but from the statements of both the Protestant and the Catholic clergy, and, in fact, from everyone who is cognizant of the true condition of affairs. As it stands, evidently the Irish poor law medical service—which in many districts includes practically the most of the rural practice, the paying cases being taken up by physicians from the towns—is a fraud.

There is no special comfort in becoming acquainted with the evils from which our neighbors suffer, but this is an example of how the public service ought not to be administered. English writers are not, as a rule, over anxious to wash their dirty linen in public or to magnify existing abuses, but the statement published by our contemporary is apparently an honest account of a condition without any redeeming features.

The commissioner does not leave the matter with a mere statement of the conditions as they exist, hopeless as they apparently are, but points a way out by reorganization, better pay, more discrimination in the appointments and better privileges and facilities generally, all of which can be met by the curtailment in certain other expenses which are likely to be useless in the future, and with a slight addition to the taxation. It is a matter, he says, in which the welfare of the whole profession of Ireland is at stake. The number of dispensary physicians is so large that the whole medical profession is in a way in closer connection with the government than with any other country. We can not expect, however, that this reform will be brought about without outside instigation. The organized medical profession in Ireland and Great Britain will have to take up the matter and see that the wrongs of the poor law medical officers throughout the kingdom are properly redressed. The *British Medical Journal* has done well to take up their cause and this showing is, we hope, a first step to the reform that is needed.

Free Treatment.—The man who would be grossly offended if some organization should send him a bundle of groceries or a dinner at Christmas will very complacently apply next day at a dispensary or hospital for free treatment. He is quite contented to have his hospital bill and doctor's bill paid by some one else or not paid at all, as the case may be, but when it comes to groceries then his pride asserts itself. Truly, the working of the human mind is mysterious and difficult to understand.—*The National Hospital Record.*

Cattle More Important Than Man.—The following from the *Sidney* (Ohio) *Journal* is not bad, coming from a lay journal:

> The legislature would not enact a law requiring patent-medicine manufacturers and venders to print in plain words on their proprietary products a formula of their contents, but it did provide a law for such an announcement of elements in proprietary foods for animals. By this is meant feed for quadrupeds, and hence the ten thousand breakfast foods so freely advertised for animals of the man and woman kind are not included. We poor, helpless bipeds must continue to munch the hay and eat the sawdust and drink the brain liquids so liberally recommended by our church journals and ethical magazines as heretofore, in ignorance of the specific elements therein contained. Here is a case wherein the "dumb driven cattle" have the advantage of us.

Anesthesia.—The blessing of anesthesia is commonly thought to concern only the patient. To free him utterly from the awful agony of a major surgical operation was, of course, the chief and striking glory of the discoverers of anesthetics. But one is likely to forget that there are other results of more real benefit to the world which follow inevitably though more indirectly. The first of these is the vast progress anesthesia has made possible in laboratory research. Operations and experiments on living animals would not have been possible in the olden times that are common now, men could not have been found in sufficient number and with the requisite insensitiveness to carry on the experiments necessary without anesthesia. The present freedom of animals from suffering would enable even the mythical fiend of the antivivisector's imagination to do his work more easily and better. In the second place, anesthesia during surgical operations has been a not negligible cause of the establishment of the nursing profession. Women could not have been found to help the surgeon under the old conditions. Thirdly, anesthesia has enabled the profession to do away with the former absolute necessity of the utmost quickness in operation. The result was a haste that made the best operations impossible. The mortality of anesthetic operations must be a hundred times better than when the patient writhed and begged for mercy.—*American Medicine.*

An Arctic Health Resort.—It is stated that a health resort is to be established in Lapland. It is proposed to erect a sanatorium on the shores of Lake Torne, a long and beautiful sheet of water at Wassijauve, near the end of the Ofote railroad. That railroad, it may be mentioned, has only one station in a distance of 121 miles. There is no human dwelling near that station, which is on the line between Sweden and Norway, and was erected solely for the requirements of the customs office. Except for a small settlement at Wassijauve, the only sign of human existence in the district is the occasional passage of a few Laplanders with their herds of reindeer. Apart from the scenery, the inmates of the Arctic sanatorium will have no external object of interest but a scientific station which has been erected with the help of private subscriptions by men of science. The work pursued at the station includes biological, geological, botanical and entomological and other investigations conducted during the summer, and meteorological, magnetic and other observations made at all seasons. The station is a solidly built block-house containing seven rooms, and it is proposed to build the sanatorium in the same way. The Arctic health resort would seem to offer ideal conditions for persons suffering from neurasthenia who require quiet and rest.—*Brit. Med. Jour.*

Use of Alcohol.—Within our profession the attitude toward alcoholics has been modified. We do not prescribe them any more indiscriminately and in as large quantities as was the custom formerly, but only in accordance with exact indications and in medicinal amounts. In the personal use of alcoholic stimulants, physicians have improved, probably in keeping with improved public sentiment. The doctor, whom it was hard to find entirely sober and of whom his admirers used to boast that he was just as good drunk as sober—true, only the proper statement would have been, just as bad sober as drunk—is seldom heard of, left here and there as a relic of the past. The great majority of our profession are temperate men, earnest, high-minded co-workers for the advancement of humanity.—*Wisconsin Med. Record.*

Association News.

THE SCIENTIFIC EXHIBIT AT ATLANTIC CITY.

Brief Resume of this Display of Pathologic Specimens, etc.

Four years ago the first Scientific Exhibit of the Association was inaugurated at Atlantic City. It was the distinctive feature of that memorable meeting. The practical benefits of the exhibit idea have been appreciated by everyone. Experience has shown the desirability of attaining two important ends: First, there should be each year the complete illumination of only a few pathologic topics, rather than a miscellaneous collection of specimens. Let the phases chosen for illustration be those of live interest to the profession, and such as are likely to be prominently considered in the Section work. Secondly the specimen groups should be demonstrated by competent persons at stated hours indicated on the official program. For the past five years those most interested in securing greater practical efficiency of the exhibit have striven for the attainment of these objects.

The coming session offers a flattering prospect of their realization. Demonstrations will be made on Wednesday, Thursday and Friday afternoons, in the Scientific Exhibit Hall, by William H. Welch, W. T. Councilman, Alfred Stengel, W. M. L. Coplin, Harvey W. Wiley, M. J. Rosenau, Henry Christian and others. The chief topics of demonstrations are as follows: Lantern demonstrations of recent work at Harvard on variola, vaccinia, scarlatina, Aleppo boil, diphtheria and typhoid; tuberculosis in all its phases, human and animal; arteriosclerosis and allied organic lesions; heart lesions; yellow fever; adulterated food products; new physiologic apparatus; miscellaneous exhibits.

Although in point of size the Scientific Exhibit will not equal those previously given, its practical effectiveness as a teaching factor will undoubtedly be greater. All exhibits should be in Atlantic City by Saturday or at latest Monday preceding the session. They should be addressed to Frank B. Wynn, Director of the Scientific Exhibit, Young's Pier.

FRANK B. WYNN, Director.

Slight Modification of Railroad Rate Conditions.

The Trunk Line Association announces that tickets to Atlantic City will be sold June 1, in addition to June 2, 3, 5

MAP OF PART OF ATLANTIC CITY, SHOWING MEETING PLACES AND HOTELS.

SECTION MEETING PLACES.

General Sessions—Young's Pier. A
Registration Bureau—Young's Pier. A
Practice of Medicine—Young's Pier.
Scientific Exhibit—Young's Pier.
Diseases of Children—Young's Pier.
Surgery and Anatomy—Steel Pier.
Ophthalmology—Steel Pier.
Obstetrics and Diseases of Women—Steel Pier
Laryngology and Otology—Steel Pier.
Hygiene and Sanitary Science—Garden Hotel.
Stomatology—Islesworth Hotel.
Nervous and Mental Diseases—Brighton Casino.
Cutaneous Medicine and Surgery—Shelburne Hotel.
Materia Medica, Pharmacy and Therapeutics—Young's Hotel.
Pathology and Physiology—Green's Hotel.
House of Delegates—High School. B

SECTION HEADQUARTERS.

Marlborough—General Headquarters.
Shelburne—Cutaneous Medicine and Surgery.
Dennis—Diseases of Children.
Seaside—Ophthalmology.
Strand—Laryngology and Otology.
St. Charles—Obstetrics and Diseases of Women.

and 6 as previously announced. Further, stop-over will be allowed at Philadelphia on the going trip within the limit of June 6, provided that the ticket is deposited at the Philadelphia office immediately on arrival. In the Central Association tickets will be sold May 31 also.

NEW MEMBERS.

List of new members for the month of April, 1904:

ALABAMA.

Hagood, J. W., Pratt City.
Jones, Julius, Rockford.

ARKANSAS.

Flinn, B. W., Little Rock.
McKinney, Asbury, Corning.
Thomason, H. E., Siloam Spring.
Toland, W. H., Mineral Springs.
Inman, M. M., Quitman.

CALIFORNIA.

Brighouse, H. E., San Francisco.
Zeile, Eugene, San Francisco.
Seymour, F. A., Los Angeles.
Nusbaumer, P. S., Oakland.
Anderson, Annie M. S., Mill Valley.

COLORADO.

Bennett, Albert S., Denver.
Rover, H. W., Denver.
Black, Herbert A., Pueblo.

CONNECTICUT.

Sullivan, J. F., New Haven.
Flynn, Jas. H., New Haven.

DELAWARE.

Lowber, Alex., Wilmington.

DISTRICT OF COLUMBIA.

Balch, Alfred W., Washington.
Wells, Walter A., Washington.
Greene, Louis S., Washington.

FLORIDA.

Hamblin, A. C., Tampa.
May, Robt. L., Jacksonville.
Bowen, Frederick, Jacksonville.
Andrade, Eduardo, Jacksonville.
Phillips, N. D., Gainesville.

GEORGIA.

Davidson, Albert A., Augusta.
Lyle, Wm. C., Augusta.

IDAHO.

Gill, J. W., Mackay.
Alley, J. N., Lapwai.

ILLINOIS.

Fairbrother, H. C., E. St. Louis.
Reedy, Ernest S., Bloomington.
Finnell, Jos. J. L., Peoria.
Wallace, Jeannette C.; Peoria.
Yates, J. N., Chicago.
Pitkin, Alice F., Chicago.
Burry, Jas., Chicago.
Gregory, W. G., Cave-in-Rock.
Griswold, C. A., Fulton.

INDIANA.

Pfafflin, C. A., Indianapolis.
Bitting, Arvill W., Lafayette.
Young, Simon J., Valparaiso.
Rieman, Wm. H., Millersburg.
Clark, J. T., Hammond.
Wood, James M., Greensburg.
Axline, J. A., Noblesville.

IOWA.

Decker, Geo. E., Davenport.
Albert, Henry, Iowa City.
Park, L. E., Tracey.
Waterbury, Chas. A., Waterloo.
De Lano, Albert H., Lone Tree.
Eglaff, Wm. J., Mason City.
Werkman, D. J., Hull.
Lyon, Paul Iliffy, Ridgeway.

KANSAS.

Brierley, J. H., Glasco.

KENTUCKY.

Morris, John Mason, Louisville.
Swetnam, Elmer, Yocum.
Sams, J. W., E. Bernstadt.

LOUISIANA.

Sims, Chas. C., Dixie.

MAINE.

Clough, Herbert R., Bangor.
Woodside, Albert, Rockland.
Giddings, Wooster P., Gardiner.

MARYLAND.

Scholl, Geo. Barr, Baltimore.
Opie, Eugene L., Baltimore.

MASSACHUSETTS.

Everett, E. E., Boston.
Pratt, Jos. H., Boston.
Olin, F. F., Southbridge.
Estabrook, Chas. T., Worcester.
Knickerbocker, Percy G., Allston.
Brown, W. A., Worcester.
Leen, Thos. F., Charlestown.

MICHIGAN.

Yutzy, Simon M., Ann Arbor.
Cooley, T. B., Ann Arbor.
White, Julia A., Battle Creek.
MacMillan, J. A., Detroit.
Bagshaw, David E., Saginaw.
Sharpe, Walter R. T., Romeo.
Belknap, Fred R., Benton Harbor.
MacKinnon, Archie C., Mio.
O'Neil, Chas. H., Frederic.
Harris, L. A., Gaylord.
Insley, Stanley N., Grayling.
Gulde, Andros, Chelsea.

MINNESOTA.

Cameron, Wm. G., Staples.

MISSISSIPPI.

Harrison, W. H., Tutwiler.

MISSOURI.

Dandurant, L. J., St. Joseph.
Rush, Wm., St. Louis.
Babler, Edmund A., St. Louis.
Miller, S. H., Joplin.
Lee, Bert J., Norborne.
Barney, Reuben, Chillicothe.
Greene, Chas. F., Poplar Bluff.

NEBRASKA.

Miller, Harold B., Lincoln.

NEW HAMPSHIRE.

Gallinger, Ralph E., Concord.

NEW JERSEY.

Walling, W. H., Atlantic City.
Shera, Geo. W., Jersey City.
Kelchner, Wm. J., Camden.
Steiner, Edwin, Newark.
Brooke, Wm. W., *Bayonne.*
Bennett, John W., Long Branch.
Tomlinson, Joseph, Bridgeton.

NEW YORK.

McKernon, J. F., New York City.
Foster, Gard W., Clyde.
Allen, G. S., Clyde.
Rusk, G. Y., New York.

NORTH CAROLINA.

Russell, E. R., Charlotte.
Monk, H. L., Spencer.
Trautham, H. T., Salisbury.
McKenzie, W. W., Salisbury.

NORTH DAKOTA.

Welble, Ralph E., Fargo.

OHIO.

Kramer, S. T., Cincinnati.
Hay, C. H., Cleveland.
Jerome, M. A., Toledo.
Graber, C. Lee, Mt. Eaton.
Mabry, Wm. C., Columbus Barracks.
Culbertson, L. R., Zanesville.

OREGON.

Hutchinson, Woods, Portland.

PENNSYLVANIA.

Bulford, D. N., Allegheny.
Robertson, Stewart, Allegheny.

State Boards of Registration.

COMING EXAMINATIONS.

State Board of Medical Examiners of South Carolina, State House, Columbia, May 17. Secretary, S. C. Baker, Sumter.

University of the State of New York, State Medical, Homeopathic and Eclectic Boards, New York, Albany, Buffalo and Syracuse, May 17-20.

Board of Medical Examiners of the State of North Carolina, Raleigh, May 18. Secretary, G. W. Pressly, Charlotte.

Nebraska State Board of Health, June 1-2, Creighton Medical College, Omaha. Secretary, Geo. H. Brash, M.D., Beatrice.

New Mexico Board of Health, Santa Fe, June 6. Secretary, D. B. Black, M.D., Las Vegas.

Iowa State Board of Medical Examiners, June 6-7, Des Moines, June 9-10, Iowa City. Secretary, J. F. Kennedy, M.D., Des Moines.

Minnesota State Board of Medical Examiners, Capitol Building, St. Paul, June 7-9. Secretary, C. J. Ringnell, M.D., Minneapolis.

Michigan State Board of Registration in Medicine, Lansing, June 14. Secretary, B. D. Harison, M.D., Sault Ste. Marie.

Ohio State Board of Medical Registration and Examination, Columbus, June 14-16. Secretary, Frank Winders, M.D., State House, Columbus.

Board of Medical Examiners for the State of Texas, Houston, June 15. Secretary, M. M. Smith, M.D., Austin.

Board of Medical Examiners of Maryland, Lehman's Hall, Baltimore, June 15-18. Secretary, J. McP. Scott, Hagerstown.

Missouri State Board of Health, Kansas City, June 20-22. Secretary, W. F. Morrow, M.D., Kansas City.

Medical Society of Delaware, Dover, and the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, June 21. Secretary Medical Council, P. W. Tomlinson, M.D., Wilmington.

New Jersey State Board of Medical Examiners, June 21-22, Trenton. Secretary, E. L. B. Godfrey, M.D., Camden.

Medical Examining Board of Virginia, June 21-24, Richmond. Secretary, R. S. Martin, M.D., Stuart.

State Medical Society of Pennsylvania, June 28 30, Philadelphia and Pittsburg. Secretary, Isaac B. Brown, M.D., Harrisburg.

Territorial Medical Examining Board of Oklahoma, Guthrie, June 29. Secretary, E. E. Cowdrick, M.D., Enid.

Nebraska April Report.—Dr. George H. Brash, secretary of the Nebraska State Board of Health, reports that at the written examination held at Lincoln, April 21 and 22, 1904, 80 questions were asked on 8 subjects, and a percentage of 75 was required. Of the 21 who were examined, 16 passed and 5 failed.

PASSED.

Lincoln Medical College (Eclectic), (1904) 90.1, 81, 75.3, 82.7, 85.1, 75 3, 86.1, 75.6, 84, 75.8, 84.8, 79.1, 75.6, 81.7, 87.
Bellevue Hospital Medical College..............(1870) 84.1

FAILED.

Lincoln Medical College (Eclectic), (1904), 57.1, 71.5, 72.5, 73.2
Ensworth Medical College..........................(1904) 69.2

Indiana January Report.—Dr. W. T. Gott, secretary of the Board of Medical Registration and Examination of Indiana, reports that at the written examination held at Indianapolis, Jan. 12, 13 and 14, 1904, 130 questions were asked on 18 subjects, and a percentage of 75 (with no one subject below 40 and no two below 50 per cent.) was required. Of the 57 who were examined 46 passed, 9 failed, and 2 did not complete the examination.

Connecticut March Report.—Dr. C. A. Lindsley, New Haven, secretary of the Connecticut State Board of Health, reports for the committee of the Connecticut State Medical Society, that at the written examination held at New Haven, March 8 and 9, 1904, 80 questions were asked on 10 subjects, and a percentage of 75 was required. Of the 21 who were examined 16 passed and 5 failed.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending May 7, 1904:

Mason, Chas. F., surgeon, granted four months' leave of absence. to take effect on or about June 1, 1904.

Maus, Louis M., deputy surgeon general, sick leave further extended thirty days on surgeon's certificate of disability.

Ford, Clyde S., asst.-surgeon, leave of absence extended ten days.

Boak, S. Davis, Lauderdale, Clarence E., Rietz, Hugo C., Waddell, Ralph W., Ware William H., and Wing, Franklin F., contract dental surgeons, will be relieved from duty in the Philippine Division on or about July 1 and sent to duty in the United States.

Mason, George L., and Whinnery, Jean C., contract dental surgeons, will be relieved from duty in the Philippine Division on or about August 17 and sent to duty in the United States.

Wolven, F. Homer, contract dental surgeon, will be relieved from duty in the Philippine Division on or about September 6 and sent to duty in the United States.

Long, Charles J., contract dental surgeon, will be relieved from duty in the Philippine Division on or about September 17 and then permitted to return to the United States by the Suez route, with leave of absence for three months.

Oliver, Robert T., contract examining and supervising dental surgeon, will be relieved from duty in the Philippine Division on or about October 17 and sent to duty in the United States.

Craig, Emmett J., contract dental surgeon, ordered from Ord Barracks, Cal., to temporary duty at Fort Rosecrans and San Diego Barracks, Cal.

Stoney, Randell C., contract surgeon, granted an extension of one month to his leave of absence from Fort Hamilton, N. Y.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending April 30, 1904:

Hull, H. F., asst.-surgeon, ordered to the Naval Hospital, Naval Training Station, Newport, R. I.

Wickes, G. L., asst.-surgeon, ordered to the Naval Hospital, Philadelphia.

Brown, H. L., asst.-surgeon, detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the *Lancaster*.

Langhorne, C. D., P. A. surgeon, ordered to continue on duty on the *Monongahela* at the Naval Station, Guantanamo, Cuba.

Wheeler, L. H., May, H. A., Belknap, J. L., and Flint J., asst.-surgeons, appointed asst.-surgeons, with the rank of lieutenant, junior grade, from April 22, 1904.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended May 5, 1904:

Pettus, W. J., asst.-surgeon general, leave of absence for seven days granted by Bureau letter of April 25, 1904, amended so as to be for three days from April 26.

Sawtelle, H. W., surgeon, granted leave of absence for five days from May 6.

Stoner, G. W., surgeon, five days' leave of absence from April 29, 1904, under Paragraph 189 of the Regulations.

Carter, H. W., surgeon, to report at Washington, D. C.

Carmichael, D. A., surgeon, granted leave of absence for fifteen days from May 12.

Young, G. B., P. A. surgeon, two days' leave of absence from April 29, 1904, under Paragraph 189 of the Regulations.

McMullen, John, P. A. surgeon, granted leave of absence on account of sickness for seven days from April 21, 1904, under Paragraph 191 of the Regulations. Granted extension of leave of absence on account of sickness for ten days from April 28.

Burkhalter, J. T., asst.-surgeon, granted leave of absence for four days from May 4.

Boggess, J. S., asst.-surgeon, to proceed to Newport News, Va., for special temporary duty.

Salmon, T. W., asst.-surgeon, relieved from duty at Stapleton, N. Y., and directed to proceed to Philadelphia, Pa., and report to medical officer in command for duty.

Stiles, C. W., zoologist, to proceed to Missoula, Mont., for special temporary duty.

Bierman, C. H., pharmacist, granted leave of absence for eight days from May 26.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from April 29 to May 7, 1904:

SMALLPOX—UNITED STATES.

California: Los Angeles, April 8-23, 23 cases, 6 deaths.

Colorado: Denver, Feb. 27-April 16, 5 cases.

Delaware: Wilmington, April 23-30, 1 death.

District of Columbia: Washington, April 23-30, 3 cases.

Illinois: Chicago, April 23-30, 5 cases.

Kentucky: Covington, April 23-30, 4 cases; Louisville, April 14-28, 4 cases.

Louisiana: New Orleans, April 16-30, 11 cases, 4 imported.

Maryland: Baltimore, April 23-30, 1 case.

Michigan: Detroit, April 23-30, 8 cases; at 97 localities, April 16-23, present.

Nebraska: Omaha, April 23-30, 4 cases imported: South Omaha, April 16-23, 1 case imported.

New Hampshire: Manchester, April 23-30, 2 cases.

New Jersey: Camden, April 23-30, 1 case.

New York: Niagara Falls, March 5-12, 3 cases.

Ohio: Cincinnati, April 15-29. 14 cases; Cleveland, April 22-29, 1 case; April 23-30, Dayton, 3 cases, 2 deaths; Toledo, 1 case.

Pennsylvania: April 23-30, Johnstown, 4 cases, 1 case imported: Philadelphia, 23 cases, 8 deaths; Pittsburg, 4 cases; Titusville, April 16-30, 23 cases.

South Carolina: Charleston, April 16-30, 6 cases, 1 death.

Tennessee: April 23-30, Memphis, 27 cases; Nashville, 6 cases.

Wisconsin: Milwaukee, April 23-30, 13 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, March 5-12, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, April 8-16. 13 cases.

Belgium: Antwerp, April 2-16, 44 cases, 20 deaths; Brussels, April 9-16, 1 death.

Brazil: Bahia, April 2-9, 1 case.

Colombia: Barranquilla, April 11-17, 3 deaths.

France: Paris, April 8-16, 22 cases, 1 death.

Great Britain: Dundee, March 26-April 16, 6 cases; Glasgow, April 15-22, 43 cases, 3 deaths; Leeds, April 8-23, 6 cases; London, April 2-16, *62 cases, 4 deaths; April 8-16, Edinburg, 5 cases; Hull, 6 cases; Leith, 3 cases; Manchester, 4 cases; Newcastle-on-Tyne, 11 cases; Nottingham, 6 cases; Sheffield, 6 cases; South Shields, 5 cases.

*Week ended April 2, 1904, cases 42, deaths 3, erroneously reported in previous report.

India: Bombay, March 30-April 5, 24 deaths; Karachi, March 28-April 3, 12 cases, 2 deaths.

Italy: Catania, April 14-21, 1 death.

Japan: Nagasaki, March 21-31, 4 cases, 5 deaths.

Java: Batavia, Feb. 7-March 19, 35 cases, 4 deaths.

Malta: March 26-April 2, 1 case.

Mexico: City of Mexico, April 10-17, 3 cases, 2 deaths; Tampico, April 16-23, 1 death; Torreon, April 17-23, 14 cases, 14 deaths.

Netherlands: Amsterdam, April 8-23, 2 cases.

Russia: Moscow, March 6-April 9, 13 cases, 3 deaths; St. Petersburg, April 2-9, 11 cases, 2 deaths.

Turkey: Beirut, April 2-16, present.

YELLOW FEVER.

Colombia: Barranquilla, April 11-17, 1 death.

℞.	Ext. hyoscyami	gr. i		06
	Ext. belladonnæ	gr. 1/6		01
	Morph. sulph.	gr. 1/10		0065

M. Ft. cap. No. i. Sig.: One such to be given at bedtime.

All instrumental interference and bladder washing should be avoided when tuberculosis is the cause, as the symptoms are only aggravated by such procedures.

In acute inflammations of the bladder *Merck's Archives* recommends the following:

℞.	Largin	gr. iv		25
	Aquæ destil. (warm)	Oii	1000	

M. Sig.: Irrigate the bladder with this solution once daily.

To relieve the pain the following suppository is recommended:

℞.	Pulv. opii	gr. xii		75
	Pulv. camphoræ	gr. xxx	2	
	Ext. belladonnæ	gr. iii		20
	Olei theobromæ q. s.			

M. Ft. suppos. No. vi. Sig.: One to be inserted at bedtime.

As an antiseptic and sedative given internally the following:

℞.	Ext. belladonnæ flu.	m. xx	1	30
	Sodii boratis	ʒii	8	
	Acidi benzoici	gr. xx	1	30
	Tinct. opii camph.	℥iss	45	
	Olei gaultheriæ	m. xii		75
	Syrupi	℥ii	60	
	Aq. destil. q. s. ad	℥iv	120	

M. Sig.: One dessertspoonful in water four times a day. When the urine is acid the following is of service as an antiseptic:

℞.	Pot. acetatis	ʒiv	15	
	Solut. potassæ	ʒi	4	
	Ext. uvæ ursi flu.			
	Tinct. hyoscyami			
	Tinct. lupulin, āā	ʒiv	15	
	Aquæ	℥ii	60	
	Syr. zingiberis, q. s. ad	℥viii	240	

M. Sig.: One tablespoonful in water after meals and at bedtime.

As an irrigation in the chronic forms of cystitis, ichthyol is recommended as follows:

℞.	Ichthyol	ʒiiss	10	
	Aquæ destil.	Oii	1000	

M. Sig.: Irrigate the bladder once daily, warm. Methylene blue has been lauded in the treatment of cystitis, given internally in three-grain (.20) doses three times a day, or locally as an irrigation in strength of 2 per cent.

Treatment of Cough.

According to Foxwell, in *Ther. Gaz.*, the irritable dry cough of gouty patients is best relieved by constitutional remedies, such as colchicum or the following combination:

℞.	Aspirin			
	Sodii iodidi, āā	gr. v		30

M. Ft. cap. No. i. Sig.: One such capsule three times daily. Along with this general treatment the throat may be painted with a 5 per cent. silver nitrate solution or a ½ per cent. solution of iodin in glycerin. In laryngeal disease the cough may be relieved by an insufflation of the following powder:

℞.	Iodoformi	gr. i		06
	Morph. hydrochlor.	gr. 1/6		01
	Amyli q. s. ad	gr. ii		12

M. Sig.: To be insufflated before each meal.

This enables the patient to eat comfortably and allays the tendency to cough. If the condition be painful and acute the inhalation of the vapor from the following is valuable:

℞.	Spts. chloroformi	m. x		65
	Succi conii	ʒi	4	
	Glycerini acidi carbol.	m. l	3	30
	Aq. bullientis	℥viii	240	

M. Sig.: As an inhalation.

For chronic tubercular ulceration of the larynx, sprays are of service. They are best employed when the patient is sitting out of doors for periods of half an hour at a time several times daily. For this purpose the author recommends a mixture of the oil of pine, eucalyptus and cassia oils with menthol and benzoin. For the frequent, dry, hacking cough of acute bronchitis some medicament is required which will moisten the tubes. For this purpose the author recommends pilocarpin in doses of *grain* 1/60 (.001) to 1/30 (.002) every four hours. For less urgent cases sodium iodid is perhaps the best drug given in three-grain doses six times a day.

To either of these, if the cough be extreme, a mild sedative may be added, as five grains of sodium bromid. Opium preparations should be avoided. In subacute bronchitis, where the cough is in excess of the expectoration, sodium iodid should be used *combined as follows:*

℞.	Sodii iodidi	gr. lxxv	5	
	Ammon. carb.	gr. xlv	3	
	Tinct. scillæ	ʒiiss	10	
	Syr. simplicis q. s. ad	℥ii	60	

M. Sig.: One teaspoonful every four hours in water.

Where the bronchial secretion is considerable in twenty-four hours the following is *of value to clear out the tubes:*

℞.	Liq. strych.	m. v		30
	Spts. ammon. arom.			
	Spts. etheris, āā	ʒss	2	
	Tinct. aurantii	m. x		65
	Aquæ q. s. ad	℥ii	60	

M. Sig.: One-half the amount to be taken and the dose repeated in two hours. In old chronic bronchitis, where the tubes produce suppurative secretion, the syrup of tar or creosote should be given, the latter given in capsule or sandwiched between bread.

In phthisis sedatives are essential. For this purpose the patient should be put to bed out of doors and given small doses of codein. If the *phlegm clings to the tubes* small linseed poultices should be placed to the neck and renewed every hour to render the phlegm less tenacious.

Furuncles and Carbuncles.

The following combinations are recommended by the *West. Druggist* in the treatment of boils and carbuncles:

℞.	Spts. chloroformi	℥i	30	
	Olei caryophylli	gtt. lxxv	5	
	Creosoti	gtt. xv	1	
	Lin. camphoræ	℥ii	60	

M. Ft. linimentum. Sig.: Apply locally; or:

℞.	Hydrarg. salicylatis	gr. ii		12
	Acidi salicylatis	gr. xv	1	
	Spts. vini rect.	℥ss	15	
	Aquæ destil. q. s. ad	℥iv	120	

M. Sig.: Apply locally on a compress.

At the same time one of the following combinations should be injected into the parenchyma:

℞.	Acidi carbol.	gr. i-iii		06-.20
	Sodii salicylatis			
	Pulv. boracis, āā	gr. xv	1	
	Glycerini	ʒss	2	
	Aq. chloroformi	ʒii	8	

M. Sig.: Ten to fifteen minims to be injected into the substance of the boil; or:

℞.	Iodoformi	gr. v		30
	Salol	gr. viii		50
	Acidi carbol.	gr. iss		09
	Spts. etheris	ʒss	2	
	Spts. vini rect.	ʒiss	6	

M. Sig.: Ten drops to be injected into the diseased tissue.

Renal and Cardiac Dropsy.

Renaut of Lyons, in *Med. Press*, recommends the following new treatment of dropsy due to kidney or heart complications:

Take one or two absolutely fresh pork kidneys, chop them up fine, and then wash them thoroughly with water. The chopped meat is then pounded up in a mortar with about twelve ounces of salt water (half a teaspoonful of salt) and allow the whole to macerate for four hours and then decant. The entire amount to be taken during the day. In order to make it palatable the patient may be instructed to add to the solution a little warm soup. This treatment should not be continued longer than ten consecutive days, when a rest should be taken for five days and the treatment re-commenced, using fresh kidneys every day.

Olive Oil in Dysentery.

Dr. H. H. Rutherford, Med. Dept. U. S. Army, of Fort Mackenzie, Wyo., in an article in *Amer. Med.* (March 12, 1904), has given some attention to the therapy of olive oil in chronic dysentery. According to his statements, experimentation has shown that olive oil increases the flow of watery bile which acts as an intestinal antiseptic. In cases of dysentery where olive oil has been administered, the amount of bile in the feces has been increased; the number of bowel movements have decreased and improved in character; there has been a gradual cessation of the signs of fermentation in the intestinal tract along with subsidence of pain and tenderness. There has been a gain in the appetite and repair of digestive facilities and rapid gain in weight and strength. The author also states that apparently positive cures have taken place after a period of two months and upward with but few recurrences in the cases he has treated. The author goes into the history of a few cases which have undergone this treatment with very favorable results.

G. Parker Dillon, in the same periodical, states it as his opinion that the value of olive oil lies in the fact that it is an easily assimilable food. The method of carrying out the treatment is as follows:

First Period.—The patient is given one ounce (30 c.c.) of olive oil three times a day for the first three days, when the quantity is increased to two ounces (60 c.c.) three times daily, and on the sixth day the same quantity is given four times a day. During the first three days the patient is to be kept on a milk diet. During the latter half one to three ounces (30-90 c.c.) of scraped beef or its equivalent of egg albumin will be added daily. During this treatment a slight loss in weight may be temporarily noticed.

Second Period.—During this period the amount of oil is given in greater quantities (not less than three ounces—90 c.c.—three times a day without discomfort to the patient) and must be kept up for a length of time in severe and chronic cases, perhaps for two months or longer, during which period convalescence will have been established and the weight regained.

Third Period.—During this period the patient is gradually restored to a full diet and the oil decreased in amount until the ulcers have permanently healed and a recurrence not probable.

Medicolegal.

Attorney Can Not Bind County for Analysis of Stomach.—The Supreme Court of Mississippi says, in the case of Jones vs. Sunflower County, that it knows of no statute in that state enabling a district attorney to bind a county by his contract with a surgeon to make an analysis of the stomach of a corpse suspected to have been poisoned. In the particular case it wishes there was such a law. In the absence of it courts can not order an appropriation of public money.

May Testify to Results of Dissection Made by Assistant.—The Second Appellate Division of the Supreme Court of New York holds, in the personal injury case of Steinacker vs. Hills Bros. Co., that it was competent for a physician who made an amputation of a leg to direct an assistant to dissect the leg after it was removed, and to testify as to the results which he saw. It was not necessary that he should have been present during the time the dissection was actually in process; it was enough if he knew the facts to which he testified.

Having Canker Not Evidence of Having Cancer.—An applicant for life insurance told the medical examiner that he had had a canker sore on his tongue, and this fact appeared in the record of that examination. The Second Appellate Division of the Supreme Court of New York says, Peck vs. Washington Life Ins. Co., that if there was any reason to anticipate danger from such canker it was the duty of the medical examiner to have determined that fact. Because the insured subsequently developed a cancer on his tongue, and because he subsequently died from the effects of blood poisoning growing out of an operation, did not establish that he had a cancer at the time of the examination, or that he had any reason to believe that the canker sore was in fact a cancer, and the burden of proof was on the company on this proposition.

Rule Applicable to Hypothetical Questions.—The Supreme Court of Illinois says, in City of Aledo vs. Honeyman, a personal injury case brought by the latter party, that, in order to take advantage of an exception on appeal to the trial court's ruling on the objection that the facts assumed by a hypothetical question were not in evidence, counsel should have called the attention of the trial court to the particular evidence assumed in the question which was wanting. The rule applicable to hypothetical questions is that the party seeking the opinion of an expert may, within reasonable limits, put his hypothetical case as he claims it has been proved, and take the opinion of the witness thereon; leaving the jury to determine whether the case, as put, is the one proved. In this case the party suing had a right to ask the question, assuming only the elements as she claimed they appeared in the evidence; and, if the question so put did not fully and fairly cover all the points, then, on cross-examination, counsel for the city had a right to change the question so as to cover the facts which they contended were applicable to the case, and which reasonably appeared from the evidence; and, having failed to pursue that practice, they can not now complain.

Measuring Damages in Personal Injury Cases.—The Supreme Court of Rhode Island says in the personal injury case of Hill vs. Union Railway Co. that the jury having found the company guilty of negligence as alleged by the party suing, it was their plain duty to assess damages in her favor in such an amount as would fairly compensate her for the injuries sustained, together with the necessary expenses incurred in connection therewith; that is, they were bound to make her whole, in so far as money damages could do so. The court says it is aware that there is no fixed standard by which the damages can be determined in a case of this sort, and that courts do not grant new trials on the ground of inadequacy of damages unless the verdict of the jury in this regard is clearly wrong. Pain and suffering and physical disability are incapable of exact measurement by any commercial standard or rule, and hence all that can be asked or expected is that in fixing damages in such a case the jury will exercise their fair and unbiased judgment. But their plain duty is to award such an amount as will compensate the party suing for the injuries sustained. What sum will accomplish this object in a given case depends wholly on the evidence, and unless it is very clear therefrom that the jury have been influenced or controlled by other considerations, or have acted under the influence of a perverted judgment in fixing the damages, the court will not review their finding. But where it is clear that the jury either wholly misconceived their duty, or else willfully disregarded the same by paying no attention to the evidence offered on the question of damages, their verdict can not be allowed to stand.

Definition of Sodomy.—The Supreme Court of Georgia says that in the motion for a new trial in Herring vs. State, the greatest effort on the part of counsel was devoted to presenting his contention that the offense of sodomy can not be committed otherwise than per anum. The court says that it has no access to the English statutes on this subject, but that this was the construction of the common-law writers seems to be settled by the weight of authority. See 3 Russ. Crim. (6th Ed.) 250; 1 Whart. Cr. Law (10th Ed.) sec. 579; Bac. Abr. tit. "Sodomy"; Clark's Cr. Law (2d Ed.) 367, and cases cited. But the judicial determinations which actually so limit the way in which this crime may be committed are few and unsatisfactory, and the text writers just mentioned, in declaring that the offense must be committed in that part in which it is "usually" committed, seem to imply that it might be practiced in some other way. In 1 Hawk. Pleas of the Crown (which was a leading text-book at the time the first penal code of Georgia was adopted) it is said, on page 357, that: "All unnatural carnal copulations, whether with man or beast, seem to come under the notion of sodomy, which was a felony by the ancient common law." The Penal Code of Georgia of 1895, sec. 382, defines this crime as follows: "Sodomy is the carnal knowledge and connection against the order of nature, by man with man, or in the same unnatural manner with woman." It will be noted that this definition contains no limitation as to the organ with which such unnatural connection may be made. It will also be observed that bestiality (which was, according to the common-law authorities, a form of sodomy or buggery) is omitted from the foregoing definition of sodomy, and is made a separate and distinct offense. Pen. Code 1895, sec. 384. The latter section reads as follows: "Bestiality is the carnal knowledge and connection against the order of nature, by man or woman in any manner with a beast." It is also to be noted that there is no limitation as to the means by which this crime may be committed. After much reflection the court is satisfied that, if the baser form of the abominable and disgusting crime against nature—i. e., by the mouth—had prevailed in the days of the early common law, the courts of England could well have held that that form of the offense was included in the current definition of the crime of sodomy. And no satisfactory reason occurs to the court why the lesser form of this crime against nature should be covered by the Georgia statute, and the greater excluded, when both are committed in a like unnatural manner, and when either might well be spoken of and understood as being the "abominable crime not fit to be named among Christians." Wherefore, the court holds that sodomy, as defined in section 382 of the Penal Code of 1895, is a crime which may be committed otherwise than per anum.

5 *A Plea for the Meatus. A. Nelken.
6 Medicine an Exact Science: Query. Joseph Clements.

1.—See abstract in The Journal of January 9, p. 118.

1½. **Pervigilium or Physiologic Wakefulness.**—Gould points out that voluntary vigil is possible for what would be considered extreme periods and quotes the experience of several prominent physicians, among them Dr. W. L. Rodman of Philadelphia, whose experience covered eight days and nights; Dr. T. B. Greenley, who at one time went for eighteen days and nights without lying down to rest, the only sleep during that time being on horseback, and Dr. R. Matas of New Orleans, who on one occasion kept awake for fifteen days and then suffered with insomnia for weeks. It would seem that perfectly normal individuals can, under special conditions, undergo long periods of wakefulness, though not as a rule without damage.

4. **Temporary Sutures for Hemostasis.**—The method suggested by Wood consists in taking a temporary deep suture under the artery, either in the wound itself or above it. The suture may be of any material, even strong linen thread, which can be removed as soon as the danger of bleeding is over or the artery tied in a more regular way. Three cases are reported in which the emergency suture was employed with advantage.

5. **A Plea for the Meatus.**—Nelken argues against meatotomy, pointing out its inconveniences and holding that the moderately contracted meatus is made responsible for more than it should be. In the last two years, since he first began to question the expediency of the operation, he has done but one meatotomy and has failed to recognize the necessity of the procedure in chronic urethritis. By a moderately contracted meatus he means one measuring between 18 and 22 French scale. The presence of stricture does not necessitate a sacrifice of the normal orifice. When we desire to employ gradual dilatation the ordinary metal sound can be used up to the caliber of the meatus. Beyond this point dilatation can be continued with the urethral dilator. The greatest objection, in spite of the inconveniences which it produces by the irritating spraying jet of urine, is the increased liability to urethral infection; Nelken quotes Belfield in support of this view.

7 Some Observations on the Surgery of the Common Duct of the Liver. William J. Mayo.
8 *Appendicitis in Children. John W. Brannan.
9 Uric Acid and Its Relation to the Clinical Manifestations of Gout and Lithemia. Egbert Le Fevre.
10 *Insufficientia Pylori. Mark I. Knapp.
11 *Hemorrhage After Tonsillotomy; Its General Consideration. H. Jarecky.

8. **Appendicitis in Children.**—Brannan thinks that this subject is somewhat neglected in the literature. He has found only four papers on the subject. With the exception of vomiting the symptoms, especially pain and tenderness, are much less constant in children than in adults. Tenderness is to be more depended on as being objective rather than subjective. When the diagnosis is once made the treatment is generally surgical. That does not mean an immediate laparotomy, but that a competent surgeon should see the case and determine whether to operate, and at what time. He has never seen a case where operation was too early, but several where it was too late.

10.—This article appeared in The Journal, April 16, p. 1005.

11. **Tonsillotomy.**—Jarecky calls attention to the importance of being prepared for troublesome hemorrhages during tonsillotomy which may occur in children and which are rather frequent in adults. When they occur he suggests using a good light and cleaning the parts to ascertain the cause. He recommends morphin, if necessary, to control the pain, and says that one should never operate without being prepared for hemorrhage.

17 *The Scope of Physical Economics: an Inquiry Into the Possibilities of Enhancing Human Efficiency Through Physical Education. J. Madison Taylor.

12. **Bronchopneumonia.**—This condition is a disease of the poor and must be studied for the most part in tenements, dispensaries and infant asylums. The immense preponderance of cases occurring amid such surroundings is explained by the character of the tissue on which it is implanted and not by the germ itself. Insufficient air and sunlight, improper food, clothing, impaired health and lack of attention to the pathologic conditions of the upper air tract are here included. Nicoll has analyzed 167 cases of the so-called primary type in the New York Foundling Hospital during the past three years, and finds the clinical picture more characteristic than in the secondary type. Bronchopneumonia is generally a secondary or complicating disease. He thinks the estimate of one-third of the cases as primary is too large. It occurs—unlike lobar pneumonia—at all seasons. Males are somewhat more frequently affected than females, and 70 per cent. of the cases were in children under two years of age. The symptoms are exceedingly irregular on account of the variety of the bacteria which singly or in combination are responsible for the primary lesion and the varying amount of the lung involved. The onset is invariably sudden and it may be ushered in by vomiting, convulsions, chills, diarrhea, disturbed expiratory action, temperature elevated 4 or 5 degrees, respirations 40 to the minute or more, and the pulse 120 or over. The ratio

of respirations to the pulse approaches 1 to 3; moist râles occur over a greater part of the chest. Subcrepitant and fine râles should be diligently sought for. They are frequently heard over only a small area, at one or both bases near the spine, in the axilla, or at the apices; with consolidation there is exaggerated, diminished or bronchovesicular breathing. Considerable areas of consolidation may be found at autopsy of which there was no evidence during life except a few râles. In atypical cases the fever rises rapidly to 104 or over, and continues, with morning remissions, for a number of days. The pulse is first rapid and strong, but later feeble. Cough may be absent and often suppressed in fatal cases. Stiffness of the neck and shoulders is marked in many epidemics and there may be muscle spasms. When a child under three years of age becomes suddenly and gravely ill, bronchopneumonia should always be thought of, even if symptoms referable to other organs, as the brain or intestines, serve to draw the attention from the lungs. If in the course of a convalescence of infectious disease the temperature suddenly rises and the pulse and respiration increase, this disorder is probably the cause. The differential diagnosis is reviewed. It may be distinguished from bronchitis of the large and medium bronchi by the lower temperature and shorter course of the latter and the absence of toxic symptoms. There is no need of any diagnosis between it and the so-called capillary bronchitis as the distinction is not a valid one. Fluid in the chest is often a complication or sequel. Bronchopneumonia is sometimes mistaken for laryngeal stenosis, but the slow, painful and characteristic respirations of the latter, the marked epigastric and sternal recessions, constitute a typical picture which should prevent mistakes. If it occurs in the course of a laryngeal diphtheria the diagnosis must be largely made on the symptoms, fever, respiration and pulse. It may lead to a mistaken diagnosis of meningitis, but the respiration in the latter is slow and usually quite unlike that of pneumonia, as is also the pulse. In obscure, acute, febrile cases in young children the possibility of bronchopneumonia should not be overlooked.

13. Pathology of Bronchopneumonia.—Bovaird describes the findings in cases of consolidated lung with associated pleurisy and the predominance of the pneumococcus and its bacteria.

(Medical News April 30/04)

14. Treatment of Bronchopneumonia.—How to care for a baby with bronchopneumonia is summarized by Northrup in the following:

1. Castor oil to clear the field of operation. It is the first aid to the injured.
2. Fresh air, cool and flowing. It reddens the blood, stimulates the heart, improves digestion, quiets restlessness, aids against toxemia. Regulate the temperature of air of the room inversely to that of the child. The patient's feet must always be warm, and the head cool.
3. Water, plenty, inside and outside. Temperature of the water as indicated by child's temperature.
4. Quiet and rest. Tranquillizing influences about patient. Undisturbed sleep.
5. Correct feedings to avoid fermentation and gas in abdomen. If there is need, high hot salines
6. Antipyretics. Water. No coal-tar products.
7. Heart stimulants Fresh air, hot foot baths. Relieving tympanites and crowding. Hot *foot-baths and* hot salines can be given in a cold room. Both can be given under the bedclothes.

Drugs.—Whisky and strychnin. These are the first drugs mentioned in this paper, unless that household remedy, castor oil, be included. Promote *general comfort* in every rational way.

How to Kill a Baby with Pneumonia.—Crib in far corner of room with canopy over it. Steam *kettle*; *gas* stove (leaky tubing). Room at 80 F. Many gas jets burning. Friends in the room, also the pug dog. Chest tightly enveloped in waistcoat poultice. If child's temperature is 105 F. *make a* poultice thick, hot and tight. Blanket the windows, shut the doors. If these do not do it, give coal-tar antipyretics and wait.

15. Behavior of the Costal Arch in Abdominal Disease.—Eliot reports cases and gives a general summary as follows:

1. The symptom of costal resistance may always be elicited in the
acute and subacute es of the contiguous un-
derlying organs. In of these same organs it
is present irregularl when the organ is in-
creased in size, or di acerbation of the chronic
inflammatory process. *In neoplasms* or cysts, increased costal resistance may be obtained only when the tumor has reached a sufficient size to mechanically interfere with the movement of the arch. 2. The degree of resistance is in direct ratio to the intensity of the inflammatory process. 3. The increase of costal resistance is most marked in that segment of the costal arch which is closely situated to the *original point* of infection, or, in the case of neoplasm, to that part of the arch which lies over the most prominent part of the tumor. 4. Its value as a diagnostic symptom is greatest in pathologic conditions invading the upper half of the abdominal cavity, especially of the liver, the stomach, the pancreas, the gall bladder, the spleen, the duodenum, the kidneys, and in extensive aneurism of the abdominal aorta. The writer has had but little opportunity to observe this symptom in supradiaphragmatic processes. In cases of empyema the abscess cavity is generally encapsulated and does not usually occupy the lowest part of the thoracic cavity. Only when so situated is there resistance of the costal arch proper. In higher positions any difference in the rigidity of the overlying rib or ribs is very difficult to detect and unsatisfactory. 5. The presence of asymmetry in the elastic recoil is very much less frequently observed than asymmetrical increase in the costal resistance, the former being present only in cases of cysts, neoplasms and inflammatory exudates in which the acute symptoms have subsided, while it is invariably absent in all the acute and subacute inflammatory. 6. With the subsidence of the inflammatory process, whether by radical or palliative procedure, the costal resistance again returns to its normal condition. 7. The presence of this symptom is very valuable, not only in facilitating accurate diagnosis, but also in serving as a useful guide to that incision through which the inflammatory focus may be most rapidly exposed and satisfactorily treated. 8. Finally, proper and skillful technic in determining the presence or absence of this symptom may be easily acquired, and, therefore, the application of the symptom may be utilized by the general practitioner and not confined to those engaged in the pursuit of any particular specialty.

17. Physical Economics.—The chief objects to be attained by exercises are to produce elasticity of the hardened tissues and a capacity to relax as well as improve nutrition. Relaxation being gained and appreciated, Taylor outlines the principles of physical economics as follows:

1. To Acquire Normal Attitudes.—Few persons are free from local or general faults of posture and most have acquired deformities.
2. To Overcome Contractures.—It is rare to find one who possesses perfect mobility of limbs, or neck, or other frequently used voluntary muscles, and it is exceedingly *common to* find the less used joints grievously stiff and contracted, especially the hip joint and the junctures of the ribs, the origin and insertion of many muscles, deep-seated tendons and ligaments.
3. To Attain Full Flexibility of the Muscles by which Alone *Their Competence Is Established.*—Here relaxation is an imperative condition. Also steady stretching is most effective, protracted till the tensions are overcome, or taught to overcome themselves.
4. To Acquire Accuracy in Movements.—Along with deliberation graduated increments of force should be employed, particularly in extensions, which should be from full relaxation in a parabolic curve of *force to* the perpendicular of extreme tension. This is the chief index of power and on this basis alone is economy of *forces* to be estimated and conserved. After accuracy is attained speed may follow, and then be of some utility. It is desirable also to secure:
5. Full capacity for extension, first passive, and later active, by which the tendons are stretched to their uttermost and through this much improvement is possible, not only in the efficiency of *the muscles, but also* reflexly in the nutrition of the centers, is enhanced.
6. *Full* respiratory capacity; the basis of oxygenation in lungs as well as muscles. This may be acquired by systematic breathing, rhythmic inspiration and expiration, both increasingly, *until* by securing invigoration of the thoracic tissues, supplemented by the abdominal muscles and especially the diaphragm, not only is full forced inspiration accomplished, but, of equal importance, fullest expiratory emptying of the lungs. This should expel the last possible remaining complemental air from the recesses of the lungs and *greatly enhance* the interchange from the residual air.
7. Circulatory capacity, the heart and great veins need development; a long story and attainable through automatic movements repeated to the limit, or by movements *of skill*, training, balance, accuracy, variety, etc.
8. Capacity for muscular endurance, *by repetition* of automatic simple acts or variegated movements, such as in fencing, the various games of skill, tennis, squash, handball, etc.
9. Muscle building; of little or no use to those not young or fairly vigorous, but of great importance to those who are markedly weak at any age, provided there is no contraindication.
10. A *combination* of muscle-building accuracy, endurance, full
muscul s and heart from such means as
fencing, her dual contests.

It is y one who desires to pursue physical
economi of acquiring full bodily efficiency,
short o to work mainly for elasticity and
accurate tensions.

22 Professional Relations, Mutual and *Public*. John H. Neal.
23 *The Hopkins-Folin Method *for* the Determination of Uric Acid in Urine. W. D. Dreyfus.

19. The Action of Sunlight in Tuberculosis.—Kime describes the apparatus used in his sanatorium at Denver. He finds that the order of improvement in most cases is cessation of chills and of night sweats, gain in body weight, increased appetite, lessening of the diarrhea, increase of strength, decline of the fever and decrease in the number of *bacilli*. While the bacteria are still to be found they may disappear after the discontinuance of the treatment. He thinks the light acts as a restorative agent, tonic and tissue builder.

20. **Epigastric Hernia.**—Cumston finds that this condition is moderately frequent, more so, however, in the male sex and in the laboring classes. It may be the result of trauma, but he thinks the most frequent causal factor is certain changes in the structures of the abdominal walls. Congenital or acquired diastasis of the recti has been present or there is an abnormal relaxation of the fibrous tissue, partly congenital and partly the result of an inherent tissue weakness. It was pointed out many years ago that the fibrous tissue from the umbilicus to the xiphoid process was always thinner and broader than that below the umbilicus and that it more readily gives way. Another important factor, however, to which he attributes the hernia to a large extent is subperitoneal lipoma deposited in the region of the epigastrium having a tendency to approach and separate the fibers of the linea alba. Two cases reported were undoubtedly caused by this condition, and two others were the result of a preformed defect in the fibrous tissue of the linea alba. The contents of these herniæ vary, but the omentum is usually found, and occasionally a loop of the small intestine or a portion of the large intestine. Even the stomach may form part of its contents. An epigastric hernia has a most characteristic appearance, but is often overlooked and medical treatment is too long resorted to. Strangulation is very infrequent, though it does occur. The sac will usually be found adherent to the ring and the contents more or less adherent to the sac. The proper method of examining a patient is to have him stand in an erect position with the trunk bent forward. By the act of coughing the hernia will be made to protrude and it disappears more or less completely in the recumbent position. If the intestine forms part of its contents, resonance will be obtained on percussion and the peculiar gurgle will be heard as it recedes into the abdominal cavity. Cases are reported of hernia from pregnancy and from trauma. The latter variety is not common. It would appear that the prognosis is very favorable if the condition is discovered in time and the proper treatment instituted. Trusses are of little use. The proper treatment is to operate radically; a cutaneous incision is made over the tumor, exposing the lipoma that is always present, and this is dissected out and the neck of the sac is sought for. The sac is opened and the contents, if any, are returned into the abdominal cavity. The sac is ligated behind the neck. The linea alba may be closed by any device desired, but overlapping or mattress sutures appear to be the most satisfactory.

21. **Uterine Cancer.**—According to Maier the reduced mortality from uterine cancer is chiefly due to timely operations, earlier diagnosis and more ready recourse to medical and surgical aid by the patient. In the present state of our knowledge we can conservatively accept, in the absence of a more tangible explanation, the view that trauma is often responsible for at least the propagation of, if not the cause of, the disease. The fact that women suffering from the so-called condition of "cancerophobia" are comparatively free from the disease is to be regarded as not altogether a coincidence, but as rather due to constant medical surveillance which the patient is under. Since the healthy uterus is less likely to undergo progressive malignant changes a highly important element in the prophylaxis should be to keep the uterine mucosa in as normal a condition as possible, and under no circumstances to neglect lacerations, inflammation, and erosions, especially during the menopause.

23. **Uric Acid in the Urine.**—Dreyfus thus describes the Hopkins-Folin method of determining uric acid:

(1) A solution of 1 litre volume containing 500 grams of ammonium sulphate; 5 grams of uranium acetate; 60 c.c. of 10 per cent. acetic acid; and distilled water to bring the bulk up to 1 litre. (2) A one-twentieth normal solution of potassium permanganate.

The method of procedure is as follows: Place 300 c.c. of urine in a beaker, add 75 c.c. of the ammonium sulphate reagent, and mix thoroughly. After the precipitate has settled sufficiently (say in about five minutes) filter through a double folded filter. When 250 c.c. of the filtrate has passed through, this volume is divided into two portions of 125 c.c. each, to serve as a duplicate. To each portion add 5 c.c. of concentrated water of ammonia, mix thoroughly and allow to stand over night. The precipitated ammonium urate is then transferred to a filter and washed with a 10 per cent. solution of ammonium sulphate. Then wash the precipitate with about 100 c.c. of water into the same beaker, add 15 c.c. of concentrated sulphuric acid, and immediately titrate with N/20 solution of potassium permanganate until the first permanent tinge of pink color appears. One c.c. of potassium permanganate solution equals 3.75 milligrammes of uric acid. From this calculate the amount in twenty-four hours.

A shorter process, but one which is less accurate, consists in the precipitation of uric acid with ammonium chlorid (30 grams for each 100 c.c. of urine), allowing it to stand over night, then filtering off the ammonium urate, washing with cold saturated solution of ammonium chloride, and dissolving in hot water (about 100 c.c.), containing about 15 c.c. of concentrated sulphuric acid, and titrating as before.

26 *Choice of Operation for Prostatic Hypertrophy. F. S. Watson.
27 *Results of Operations on the Prostate, Massachusetts General Hospital, from Jan. 1, 1892, to July 1, 1893. Hugh Cabot.
28 *Use of the Cystoscope in Determining What Operation is Advisable in Prostatic Hypertrophy. F. C. Balch.
29 *Brief Résumé of the Present Status of the Treatment of the Enlarged Prostate. Arthur T. Cabot.
30 *Prostatectomy—Spinal Anesthesia. F. B. Lung.

24, 25, 26, 27, 28, 29 and 30. **Prostatic Hypertrophy.**—Prostatic hypertrophy and its various relations is discussed by a number of authors. Crandon describes the surgical anatomy of the prostate and Chute the gross pathology and mechanism of its obstruction. In discussing the choice of operation Watson reviews and tabulates the results in 2,600 cases and concludes that the perineal operation done according to the best technic is the most satisfactory, and the method of choice. The suprapubic and Bottini methods both, however, have their place; the former in cases in which the very large middle lobe makes the perineal operation difficult and the Bottini operation in patients whose condition is such as to expose them to shock or post-operative pulmonary complications. If a Bottini can not be performed and something must be done for relief a palliative operation for drainage may be performed. H. Cabot summarizes the results in the Massachusetts General Hospital and Balch points out the advantages of the use of the cystoscope, especially where the galvanocautery has to be resorted to. As regards the present status of operation A. T. Cabot thinks that the Bottini with cocain anesthesia may be advisable in very feeble patients where the organs are too unsound to bear other operations, but he thinks the perineal operation is less dangerous and more sure of giving good functional results. He notices the fact that in many cases where the gland is rather blindly shelled out lacerations forming flaps in the urethra and interfering with micturition may still remain. Complete prostatectomy, however, is so well supported by evidence as the most satisfactory that it is the operation to be preferred. In some cases, however, thorough removal of the third lobe will accomplish all that is needed. The operation is one that should not be neglected. Its most rational employment is where the bladder is opened for other purposes and this condition of the prostate noticed. Its removal adds little or nothing to the danger of the operation, and there is a very fair chance of recovering the power of urination. Lund reports a case performed under spinal anesthesia by the Morton method, putting powdered cocain in a sterile syringe, withdrawal of the spinal fluid and allowing it to dissolve the cocain and then re-injecting it. The operation required the ultimate removal of the middle lobe by the suprapubic wound, and he had good results.

31 *Concerning the Acidimetry of the Gastric Juice. J. Henry Schroeder and Henry W. Bettmann.
32 Suppurative Diseases of the Middle Ear. Samuel Iglauer.
33 *Strangulated Bowel, Laparotomy. Earl Harlan.*

31. **The Acidimetry of the Gastric Juice.**—Schroeder and Bettmann have experimented with Toepfer's indicator, tropeolin, alizarin, and congo red, giving their reactions with the different acids in distilled water, the comparative sensitiveness and their end reactions, with special reference to Knapp's statement that Toepfer's test is unreliable for free HCl. From the result of their studies they find that the weak solutions of organic acids may interfere with the end reactions of these indicators. They do not think it probable that Toepfer's re-

agent will ever give positive reactions when free HCl is totally absent and in that case the free organic acids will combine with the albuminous substances, and can not be detected by Toepfer's test.

Denver Medical Times.

April.

34 *Report of X-ray Therapeutics. G. H. Stover.
35 *Volvulus of the Stomach. C. D. Spivak.

34. **X-Ray Therapeutics.**—Stover gives the report of considerable experience in *x*-ray treatment of various conditions. It is his opinion that the *x*-ray is the specific for epithelioma—better than the knife or caustics, as it does not disturb the healthy tissue, and as the final cosmetic effect is infinitely better. He does not think recurrence is any more frequent than after other methods, and would probably be found less so. If it should occur the ray can be again applied and no tissue necessarily sacrificed. In carcinoma the results are not so gratifying, especially in deep-seated ones, but he thinks the time will come when the results will be much better than now. For cancer of the breast or cancer of the internal organs surgery is the proper treatment, but it is well to use the rays before and after operation. Primary raying may destroy some outlying and but little developed invasion and help to render the tissue sterile, thus preventing infection. He has exposed his left hand considerably to the rays during the past seven years, and injuries, cuts, etc., heal up much more readily than in any other part of the body and without suppuration. He is watching the development of what one writer calls a precancerous keratosis due to the *x*-ray, but so far has not seen any bad effects. In bone tuberculosis the results have been gratifying, and he hopes the results in glandular tuberculosis will continue to be good. He is not ready to say much as regards the other forms. He thinks there is too much rushing into the *x*-ray treatment, and that there will be a reaction against it, but hopes the pendulum will not swing too far, as it has established a rightful place for itself.

35. **Volvulus of the Stomach.**—Spivak remarks that volvulus is not confined to the intestines. He quotes from the literature of reported cases, 8 in number, and remarks that where adhesions, contractions and tumors exist the occurrence is explainable by some effort of the imagination, but it is hard to solve its mechanism where no organic changes are found. One thing is certain, that volvulus of the stomach is never produced spontaneously. The condition works slowly and silently for days, weeks and possibly longer. The conclusions are given as follows:

> 1. The occurrence of volvulus of the stomach is a possibility beyond the shadow of a doubt; it remains, therefore, for physicians to bear this condition in mind when making a differential diagnosis between pyloric obstruction, occlusion of the bowels, poisoning, cyclic vomiting, cholelithiasis, peritonitis, etc.; for surgeons to be ready to operate when necessary and not to forget to empty the stomach of its contents: . . . . and, for authors to devote some space to this condition in their text-books on diagnosis and surgery. 2. Volvulus of the stomach occurs in all ages and in both sexes. 3. Digestive disorders may be considered as etiologic factors. 4. From a pathologic standpoint volvulus of the stomach may be divided into (*a*) that due to organic changes produced by adhesions, and (*b*) that in which no visible organic changes have taken place. 5. The characteristic symptoms of volvulus are: Sudden onset; distention, which commences in the left hypochondriac region, and which gradually increases in size; a tumor, which gives on percussion a tympanitic sound; vomiting or regurgitation immediately following ingestion of food or drink; no belching, no escape of flatus; inability to pass a sound into the stomach. 6. When the condition is recognized, early operative interference is indicated, and recovery is almost certain. Since the ability of turning around its axis is vouchsafed the stomach, I verily believe that the next thing we hear will be invagination of the stomach—the pylorus will slip into the funnel-shaped cardiac orifice, and for aught I know, may traverse the esophagus and prolapse itself from the mouth. To my articles of medical faith I shall add: I believe anything one may say of the stomach.

44 An Interesting Case of Inherited Syphilis. George F. Suker.
45 Present Status of the Mechanical Treatment of Spondylitis. Wallace Blanchard.
46 Straightening of the Curvatures of Tubercular Spondylitis. John Ridlon.

42. **Accessory Sinuses.**—Eckley's conclusions are in substance that: The accessory sinuses of the nose in man are phylogenetically very ancient structures and figure physiologically as feeble, subsidiary, respiratory organs. The maxillary sinus in the higher vertebrates has its prototype in the amphibian accessory nasal chamber in which it was an olfactory organ, hence, phylogenetically, the antrum in man is an obsolete organ of smell. For reasons not explained, the sinuses develop *pari passu* with the generative organs and there is evidence of an intimate physiologic relation between these two. The variations, even in healthy sinuses, are so great that it is risky to attempt any analytic classification as to size, shape or openings. For embryologic reasons each sinus is a law unto itself. The sinuses are supplied by the trifacial nerve, hence reflex phenomena between them and the peripheral cervical nerves are possible. The specialist should bear in mind the possibility to reversion to structural fixed types in the lower vertebrates. Operations on the sphenoidal sinuses are anatomically unjustifiable. A sound tooth should never be sacrificed. The nasal route of gaining entrance to the antrum is never dangerous.

Therapeutic Gazette, Detroit.

April 15.

47 *Case of Total Laryngectomy (Unsuccessful) and a Case of Abdominal Hysterectomy (Successful), in Both of Which Massage of the Heart for Chloroform Collapse Was Employed, with Notes of 25 Other Cases of Cardiac Massage. W. W. Keen.
48 Some Observations on the Surgical Physiology of the Vascular System. Geo. W. Crile.
49 *The Advantages of Abdominal Over Vaginal Hysterectomy in Carcinoma. John B. Deaver.
50 *Use of Atropin in Ophthalmic Practice. Aaron Brav.

47. **Massage of the Heart.**—The title of Keen's article explains the case, but principal stress is laid on the attempted relief by massage of the heart. He also reports another case of chloroform collapse with massage of the heart and recovery, the operator being Dr. Ingelsrud of Tromso, Norway. Keen also reviews the other reported cases, omitting, however, until the close of the article the case reported by Cohen in The Journal, Nov. 7, 1903. With this case the total number of cardiac massages to restore its action in heart failure during surgical operations is 28, with 4 recoveries by this means.

49. **Abdominal Hysterectomy.**—Deaver advocates the total ablation of the uterus by the abdominal route in early cancer of the cervix, holding that the operation is more promising than when done by the vaginal route.

50. **Atropin in Ophthalmic Practice.**—The indications and contraindications of atropin in ophthalmic practice are noticed by Brav. Among the former he includes correcting errors of refraction in patients under 40 years of age, unless there are special contraindications to its use. No other drug is as good in measuring refractive errors. In the spasms of accommodation with resulting apparent myopia, it is the drug to clear up the condition. In the treatment of convergent strabismus, due to an excessive degree of hypermetropia in its early stage, it is of value as paralyzing the accommodation, keeping the eye focused for distant vision, thus preventing undue convergence. In diagnosing posterior synechia and seclusio pupilla atropin is of considerable value. In various inflammatory conditions it is a most valuable therapeutic agent, acting as an antiphlogistic by contracting the blood vessels and a direct sedative and analgesic. In disease of the cornea of almost every type atropin is indicated, and especially in the interstitial and parenchymatous types of the disease. In corneal ulcers it is also invaluable, and it appears, according to the author, that the increase of intraocular pressure it produces in these cases is so slight that it may be overlooked when we consider its advantages otherwise. It is essential in the treatment of disease of the iris and ciliary body and of benefit in scleral wounds and recent injuries. In disease of the uveal tract, choroiditis, retinitis, it paralyzes the ciliary muscles and pre-

vents the constant pulling of these bodies forward. It is also indicated in circular iridodialysis. The contraindications are glaucoma; in all conditions with an increase of intraocular tension, in people above forty for the correction of refractive errors and in cyclitis as increasing the pain; and in ulcers of the cornea with threatening perforation the greatest caution should be used in its employment. In radial iridodialysis atropin is contraindicated. Its employment in children especially should be with care. Some people have a marked intolerance and toxic symptoms are easily produced. The preparation should not be contaminated. The solution should be neutral in reaction and not too strong, and while using it the lachrymal sac should be compressed or the lid everted. The solution should be aseptic, especially in inflammatory conditions by a fraction of bichlorid. The diagnosis should be certain and the eye should not be glaucomatous. No more than three drops daily should be instilled. It should not be used after forty-five years of age.

51 Vernal Catarrh: Pathologic Study. Richard H. Johnston.
52 *Association of Cataract with Uncinariasis or Hook-worm Disease. A. W. Calhoun.
53 A Luminous Test Cabinet. Nelson M. Black.
54 *Case of Panophthalmitis Following Cataract Extraction in an Apparently Healthy Eye—Cause. Pneumococcus Infection. Hiram Woods and Richard H. Johnston.
55 *An Unusual Accident to a Glass Eye. B. L. Millikin.
56 An Adjustable Lid Speculum. Mark D. Stevenson.
57 Use of Prisms in Determining the Refraction by the Shadow. Charles D. Jones.

52. **Cataract and Uncinariasis.**—Calhoun calls attention to the association of cataract with hook-worm disease. He has operated on several cases within the last few months and has become impressed with the conviction that the hook-worm was the cause of the cataract and can also recall several other cataract cases in persons having similar symptoms that occurred in his practice before the recognition of the parasite.

54. **Panophthalmitis Following Cataract Extraction.**—Woods and Johnston report the case of a cataract extraction in an apparently healthy eye which was followed, without any obvious causes of infection, by general panophthalmitis which left the left eye a painless stump. A bacteriologic examination found the diplococcus in abundance in the pus of the affected eye. The aseptic precautions seemed to be complete and Woods asks whether a cold that the patient had six weeks before the operation could have left the organisms which at once invaded a fresh wound, and whether the case suggested the propriety of gauze covering for the mouth and nose of the operator and spectators, a point which was somewhat emphasized by Dr. Gifford at the last meeting of the American Medical Association. The pneumococcus appears from the literature to be a frequent cause of panophthalmitis.

55. **An Unusual Accident to a Glass Eye.**—Millikin reports the case of an explosion of a glass eye in a woman who was subjecting it to considerable heat in the process of ironing clothes and asks whether the expansion of air in the cavity of the eye can not be the cause of the explosion. The eye was what is called the "reform" eye, in which the air is partially exhausted. The manufacturer suggests that possibly the vacuum was too complete and that anything that would crack the eye would allow the air to rush in to fill up the vacuum, possibly causing the sharp report which occurred. No very serious consequences followed the explosion.

59 Case of Bronchiectasis Following Pneumonia, Complicated with Yellow Fever. J. T. Moore.
60 *Some Observations in Intestinal Anastomosis, with a New Technic. J. F. Eanes.

60. **Intestinal Anastomosis.**—Eanes has experimented on dogs in producing intestinal anastomosis by means of a bobbin composed of the sterilized pasteboard portion of a shotgun cartridge split on one side so that it can be adapted to the lumen. He thinks the device worth mentioning, since many surgeons are not prepared with other appliances and this is generally available. In his experiments on eight dogs, using the duodenum, jejunum and ileum as the field of operation, he has not had a single failure. The cylinders were passed in four to eight days.

68 Surgical Treatment of Gallstones; with a Report of Six Cases. J. Wilson Poucher.
69 Hysterectomy for Infectious Disease of the Uterus and Uterine Appendages. H. C. Deaver.

61. **Retroversion of the Uterus.**—Martin's paper is mainly a review of the various operations for the treatment of retroversion, reporting also some cases of the Alexander operation he performed. The main part of the article is a review of the literature.

62. **Postoperative Paresis and Adhesions.**—Craig assigned himself the problem of finding a means of regulating peristalsis after operations by counteracting the stimulated reflexes acting through the splanchnics and restoring energy to the exhausted nerve endings and muscles of the intestine. He first experimented with salines, but came to the conclusion that their use in this condition was irrational. He then followed the line suggested by Murphy in giving a full dose of the extract of cascara a few hours before the operation. This, however, has serious drawbacks and it does not seem practicable in emergency operations. While he was equally dissatisfied with calomel and salines postoperative and cascara preoperative, the article of the late F. A. Packard came to his aid on the use of eserin. On investigating eserin salicylate he finds that though the active principle has been considered extremely poisonous, it is not more so than many other commonly employed drugs and that it is highly spoken of by most clinicians in the treatment of atrophy of the intestinal muscular coats, especially by von Noorden, who is the only one that had regarded the use of eserin as a remedy for postoperative paresis. Craig has employed it subcutaneously because most easily employed in doses ranging from 1/60 to 1/40 of a grain, according to the susceptibility of the patient to respond to cathartics. More than 1/40 has not been found necessary. Active peristalsis can do far more to inhibit the formation of adhesions than can possibly be accomplished by any dusting powder or foreign membrane and does not overtax the peritoneum. The effects of peristalsis, he says, can be materially enhanced by leaving within the peritoneal cavity a moderate quantity, say a liter, of sterile salt solution, which enables the intestines to float away from the abraded surfaces. It is a fortunate thing that the natural antidote to the drug is one that co-operates with it as regards peristalsis—atropin. Moreover, nothing better prepares the patient for anesthesia than a small dose—1/50 to 1/100 of a grain—of atropin sulphate either by the mouth an hour previous to anesthesia or subcutaneously immediately before. Some have objected on account of its aggravating the patient's thirst, but the use of eserin has just enough counteracting effect to render the throat moist. He says anyone adopting this method of treating celiotomy patients will be impressed with the great comfort and general well-being of the patient as compared with the hours of distress and more or less abdominal distension, while we have been waiting until the patient can take a cathartic by the mouth. The only discomfort thus far observed was a rather severe epigastric pain in two patients, which yielded to codein sulphate by the mouth in ½-gr. dose, the codein interfering with the peristalsis far less than morphin. He thinks, however, that the eserin had nothing to do with the pain and that it could probably be attributed to the prolonged maintenance of the Trendelenburg position in difficult operations. He also assists the peristalsis, unless special

contraindications exist, by having the nurse turn the patient every half-hour until the peristaltic rumbling is heard. The patient is encouraged to assist in turning herself frequently as soon as she has recovered consciousness. Three cases are reported.

63.—*This article appeared elsewhere.* See THE JOURNAL of April 23, ¶1, p. 1100.

64. **Plastic Surgery of the Generative Organs.**—Newman offers some suggestions as to why plastic surgery of the female genitalia should be undertaken, and the qualifications of the operator. He insists particularly on the importance of recognizing the fact that operations are not simply cosmetic, but are for the restoration of functions, hence the superficial skin unions seen in some perineorrhaphies are hardly to be considered useful. Gynecic judgment is required in all cases. The woman's pelvic organs are largely the foundation of her health, and if their functions are interfered with her general health suffers. This brings about another suggestion to which he attaches the greatest importance, namely, the necessity of operating at a single sitting instead of dragging the surgery out in numerous operations. He makes it a practice to do at one and the same time all the different procedures which are pathologically justified, putting all the parts into as nearly as possible the normal anatomic relations and giving nature the best opportunity to do what is required of her. The gynecologist can then assure the patient that she is as nearly normal as mechanical surgery can make her, and she should be fully instructed as to the rational course of life for her to obtain vigorous health. It may take time to overcome the disordered functions and habits, but it is best done by this method of operation.

65. **Uterine Displacements.**—In the treatment of uterine displacements the first and most important element is to have some estimate of the causative factors under which the case can be classified, together with a thorough appreciation of all the local uterine and peri-uterine lesions and conditions. A complete and accurate diagnosis and a rational treatment based on this are not always easy. The first consideration, Palmer says, is improvement of the general health by diet, exercise, rest, baths, medication, posture, etc. Constipation must be relieved. Local uterine and peri-uterine alterations must be bettered. The bulk and weight of the displaced organ must be reduced by depletion, as the puncture and curette; the suppuration aided by general tonics and local astringents. The intra-abdominal pressure from above should be reduced by the proper adjustment of the clothing, better posture and the conservation of the normal angle of 55 degrees of the pelvic brim to the horizontal plane and increasing the tonicity of the uterine walls by quinin, strychnin, etc. In all retroversions the broad and round ligaments are more or less lax and the uterus in a passive hyperemia. Irreducible retroversions from adhesions usually call for abdominal section, indicating a chronic pelvic peritonitis with diseased appendages. Before using the pessary or major surgical operations it is worth while to see what electricity can do. The pessary itself is a choice of evils, but has its place like a crutch or cane, though never intended for constant or indefinite use. Its proper adjustment requires a thorough knowledge of gynecic pathology, much experience and not a little tact in manipulation. After having done all that can be done as indicated then surgical interference may be called for. In the first place all lacerations should be repaired and a skillfully performed sharp curettement of the whole endometrial cavity, a tracheoplastic operation, etc., the removal of primary causative factors in many cases and the withdrawal of aggravating associations. The Alexander operation, Palmer considers, has a very limited field and almost any displacement thus benefited can likewise be equally improved without operation, only with more time. Ventrofixation has a seemingly wider field, but the position of the uterus after this operation is not physiologic and is likely to interfere with future pregnancies. Hysterectomy is justifiable after marked prolapse in certain cases when pregnancy becomes impossible because of age or an artificial menopause. The pelvic circulation must be benefited in any case. No method of shortening the long round ligaments is equal, he says, to the intra-abdominal. The weakest feature is the comparatively feeble points of attachment of the anterior ends of the round ligaments. Most of the operations that have been advised for the rectification of posterior malpositions are more or less unsatisfactory or useless. He speaks particularly of the advantages of the utilization of the plastic uterine and vaginal operations and the well-performed Hegar operation on the perineum or posterior vaginal wall in which the denuded area should vary in length, width and shape, but always somewhat triangular, is a wonderful aid in many intrapelvic infirmities. The Stoltz operation on the anterior vaginal wall is much enhanced, he thinks, in its execution and results by denudation of a rather long, deep eliptical area, varying to suit the individual conditions and the stitching together of the raw surfaces with silkworm gut transversely. The anterior wall is then narrowed and strengthened and not shortened, as it would be by the ordinary Stoltz operation. A thoroughly done Stoltz operation, modified as suggested, and an equally broad and deep Hegar, may so strengthen and narrow the vagina that a descending uterus can not pass through it. The denudations should be abundantly wide and more or less deep, to and into the muscular coats of the vagina, so that when the sutures are passed transversely, firm and strong supporting partitions are secured and maintained. He advises with undue relaxation of the pelvic floor to utilize a continuous suture into the deep pelvic fascia with fine catgut before the superficial layers of silkworm gut are adjusted. This method secures complete and accurate coaptation of the opposing denuded areas and thorough construction of the solid perineum and vesico-vaginal septum.

67. **Uterine Ligaments.**—According to Goffe the uterus is supported and retained in position exclusively by its ligaments; each has a certain function, but the only one whose exclusive work is that of support is the uterosacral ligament. It furnishes the principal sustaining power. An additional function of the uterosacral ligament and the muscle fibers at the base of the broad ligament is mentioned. It is connected with the process of parturition and consists in rhythmically lifting the cervical tissue over the head of the child as uterine contractions and muscular pressure force the head of the cervix down toward the vulva, the process being similar to the slipping of a glove onto the finger.

74 *New Method of Treating Foreign Bodies in the Cornea, as Evidenced in the Treatment of 808 Recent Consecutive Cases. Edwin M. Fuller.

74. **Foreign Bodies in the Cornea.**—The point insisted on by Fuller is to denude the cornea well away from the part in which the foreign body has been lodged, leaving a free, smooth base, thus avoiding resulting corneal ulcer or scar. He prefers a fairly strong solution of cocain used once to a weaker solution used two or three times in the operation. An astringent solution like glycerotannin should be employed, as it will frequently prevent conjunctivitis. The use of hot baths, freely the first few hours, will often arrest such a complication. Colored glass should be prescribed at once. If a conjunctivitis or iritis arises total exclusion of light. Never bandage the eye and force the upper lid against the eyeball after the removal of foreign bodies. Oiling the edges of the lids of the offending eye at bedtime to prevent them sticking together is of importance. He condemns the removal of foreign bodies from the cornea by the laity with toothpicks, knives, etc.

77 Medical Paris During the Reign of Louis Philippe. J. Chalmers Da Costa.
78 Experimental Toxic Leucocytosis. J. G. Silverman.

75. Cervical Rib.—Riesman finds that cervical rib may exist without symptoms, which when present are local and functional. The local symptoms are a prominence above the clavicle or feeble pulsation high in the supraclavicular fossa. The functional symptoms are circulatory and nervous. The principal circulatory ones are a form of feebleness, absence of pulse, coldness of the extremities, occasional cyanosis and edema. The chief nervous symptoms are pain in the distribution of the brachial plexus, with parasthesias such as numbness, formication and awkwardness in the use of the hand, and in some cases weakness and atrophy. In cases of brachial neuralgia the possibility of the presence of the cervical rib should be considered. The treatment, except in the mildest cases, is excision of the rib.

76. Typhoid Fever Eruptions.—Edsall describes a peculiar vesicular eruption occurring over the sacrum, the buttocks and loins of typhoid fever patients and extending over the back and thighs. The cultures gave the pure growths of the *Staphylococcus aureus.* The cause of the infection he attributed to carelessness in the use of the bedpan and insists on more care as toward utensils than is commonly given them. The infection seemed to be carried in these cases by the bedpan.

83 Treatment of Syphilis, with Report of Two Obstinate Cases. C. G. Clark.

80. Intestinal Peristalsis.—Ott reports experiments on rabbits, cutting the right vagus and sewing up the wound. On the fifth day the wound was reopened and the peripheral end of the vagus irritated, when it was found that the cardio-inhibitory fibers had degenerated and vagus irritation had no effect on the heart. During the irritation of the vagus he studied the movements of the intestines and under these conditions it was found that peripheral irritation of the vagus produced a slowing and in some cases an arrest of movement for half a minute. He thinks the results prove that the vagus contains intestino-inhibitory fibers.

86 Case of Pancreatic Lithiasis with Atrophy and Lipomatosis of the Pancreas, Associated with Pulmonary Tuberculosis. George P. Muller.
87 Case of Filaria Immitis in the Heart of a Dog. Frederic H. Howard.

84. Muscle Infection in Pulmonary Disease.—Coplin has studied the condition of the intercostal muscles in disorders affecting the lungs and pleura and finds marked changes, dissociation of fibers, leucocytosis, infiltration, granularity, etc., and the presence of bacteria. The cause seems to be clear. In inflammations of the lung and pleura the lymphatic systems are engorged and the toxic materials are brought in close proximity to the intercostal muscle and diaphragm. It seems probable that the lymphatic channels may be occluded and the collateral currents must form through the intercostal muscles, exposing them to the dangers induced by contact with the toxic lymph. The influences of changes on the thoracic wall are suggested and alterations in the intercostal muscles may explain many side symptoms of pulmonary disease, etc.

8 *Intraspinal Cocainization. Alfred S. Gubb.

2. **Roentgen and Radium Rays.**—Morton concludes that we have in the *x*-rays an agent of considerable power, capable of doing much good. The results in rodent ulcer alone are a great triumph. It is capable, however, of doing much harm in the hands of unskilled and unqualified persons. He opposes the popular notion that the instruments are all in all, and deprecates the way the work is being commercialized in London in the various institutions that have started up. One of the worst features of the case is that many regular members of the profession habitually employ unqualified men to do their electrical work. Proper medical training is as necessary here as elsewhere. As regards the practical application of radium rays, they are the same as the *x*-rays. While on account of the high price and the scarcity of the substance we lose in quantity there are some advantages in its convenient and direct application. The chief results so far have been in the treatment of rodent ulcer and lupus vulgaris and the number of reported cases are increasing. He things the most convenient apparatus is the small glass tube, one or two inches long, containing five milligrams, which can be applied for half an hour or so, as at the London Hospital. There the applications are made every second or third day, and there have been no severe reactions as yet. When an adequate standardized supply of radium is obtained, the applications will be very much simplified. Their value in cases of malignant disease is still under investigation, but some favorable results have been reported, at least as regards the relief of symptoms.

6. **The Danysz Bacillus.**—Danysz here describes the coccobacillus which he has isolated in spontaneous disease of field mice, and gives the results of experiments. He shows from Kirter and Kottyen's experiments in the Dunbar laboratory that the culture diminishes in virulence by passing through animals. It is, therefore, difficult to maintain the virulence or to increase it when it is found to be small. It can be increased only by making a large number of experiments and thoroughly testing the virulence of the cultures. When making experiments on a number of rats at a time, say thirty or more, it has been found that one or two cultures may be obtained more virulent than those from the others, and this virulence may be maintained for two or three months. By working in this fashion he has succeeded in keeping up the supply of virulent cultures for eight years. He gives an account of work in Odessa and its suburbs where the bacillus cultures were used with great advantage in the destruction of rats, and absolutely no ill effect to human beings or domestic animals was reported from their use.

8. **Intraspinal Cocainization.**—Gubb reports results with this method of anesthesia; he has been very favorably impressed with it.

9. **Skull Fractures.**—Rawling's third lecture treats of injuries to the nerves in skull fractures. The olfactory nerves are affected when the cribriform plate is involved. The optic nerves are sometimes involved, though gross lesions of this nerve are not so common. The seventh and eighth are more commonly involved than any other basic nerves in basic fractures owing to their complicated intrapetrous course. In a transpetrous fracture the nerve is cut off completely near the genu and irreparable damage is often done. The ninth, tenth and eleventh nerves in the jugular foramen generally escape injury. He thinks that any implication of the condyloid foramen and the twelfth nerve is improbable and must be rare. The temperature in head injuries is classed under three types: First group, an earlier subnormal temperature, then a steady and progressive rise. The prognosis is unfavorable. In group two, the temperature is at first subnormal, but rises gradually to 101 or 102 and then remains for awhile. This indicates the crisis of the case and the subsequent fall, a favorable outcome, while a rise would indicate the contrary. In the third group, the temperature, at first subnormal, remains at that level or rises to about normal without any further subsequent elevation. In the former case the patient never recovers from the collapse; in the latter the injury is so slight that the stage of shock being neither prolonged nor deep is not subsequently followed by a reaction. These three groups of temperature changes are so constant that he considers the temperature chart an almost infallible guide to the prognosis of the case. Brain lacerations and concussions are noticed at some length. In most cases the typical compression symptoms are absent. The special symptoms of compression are probably referable to increased pressure on the vital centers in the medulla. In the early stages of shock and collapse the ordinary treatment must be adopted; the head kept low and the heart's action stimulated. The temperature should be taken every quarter of an hour, and as soon as a reaction appears, the head should be elevated and the body depressed, ice applied to the head and warmth to the trunk, with free venesection, the amount of blood to be withdrawn being in proportion to the severity of the injury and the violence of the reaction. Free bleeding is especially useful in lessening the subsequent intracranial exudation and pressure. The lower bowel should be emptied early by copious enemata, purgatives given, and the bladder periodically attended to. All punctured fractures and all markedly depressed fractures call for operative interference, but in many cases the question of injury to the internal table is dubious. The tendency is to establish an expectant treatment. Still he thinks a large number of these cases develop subsequent symptoms and that more general trephining and exploration is advisable in most doubtful cases. In comminuted vault fractures a thorough exploration generally necessitates the removal of the fragments and their reposition is open to objections, as they are a source of irritation and increase the tendency to

the formation of adhesions between the dura mater and the bone; the actual utility of their reposition is open to doubt. It is advisable, therefore, to remove all small fragments and to protect the brain by metal plates cut to a suitable size, shaped, pegged and nailed in position. When there is brain laceration and the chances of suppuration are great the plate should only incompletely close up the bony gap. In basic fractures without an obvious compressing agent present, such as a foreign body, middle meningeal hemorrhage, etc., he suggests that the cerebellar fossa should be trephined as low down as the muscular attachments will allow, accordingly, as the force was applied to the right or the left side of the head, the opposite cerebellar fossa should be explored. The opening should be of good size, the dura mater opened and the bone not replaced. A drainage-tube should lead through the flap to the gap in the skull. The cases where this is advisable are almost always fatal, but this method, he thinks, may add to the chance of recovery by lessening pressure in the region of the fourth ventricle. He pleads for long attention to all head cases. Six months at least should elapse before the patient should return to his ordinary occupation.

10. **The Neurology of Vision.**—Parsons' second lecture treats more especially of the innervation of the pupil.

15. **Myxedema.**—The mental state in myxedema, according to Wolseley-Lewis, is simply the retardation of psychomotor action. The perception is usually good, the memory is retentive, though less impressible, and the judgment and reasoning power are not defective. Ideation and the formation of concepts do not seem to be diminished and the association of ideas seem to be good, but there is a retardation of thought and the elaboration of an idea is difficult. It is in the volition and action that the mental symptoms of the condition manifest themselves. Changes in the mental condition of cases of myxedema are almost confined to the sphere of action. Wolseley-Lewis seems to think it necessary to suppose that either some toxin in the plasma surrounding the motor cells inhibits the chemical processes that originate the motor impulse or that the absence of some substance from the blood interferes with the discharge. This toxin is neutralized or this essential substance is supplied by thyroid extract, and he has observed that the simultaneous exhibition of syrup of iodid of iron adds to its action.

18. **Thorium Nitrate.**—Sharp has experimented in hypertrophic pharyngitis and laryngitis by using an inhaler with a solution of neutral thorium nitrate, apparently with very good results. Whether these are due to emanations from the thorium he does not positively say, but he feels encouraged to give the treatment further trial.

20. **The Declining Birth Rate.**—McLean, the government statist of Victoria, has taken up the question of the decreasing birth rate in that state, and concludes that it is not so actual a factor as regards increase and decrease of population as has been held. The country has a reduced birth rate owing, in part, to the fact that a specially selected population at first occupied it, and this has with time been replaced by a less fecund but more normal population. It has also suffered from emigration and urban concentration, both of which tend to diminish the birth rate. The average physique of the women is not equal to that of earlier years, and their fecundity is correspondingly diminished to some extent. The increase of the average age at marriage is too obvious a cause to call for special comment. The lowered death rate, however, keeps the increase of population above that even in some countries where there is a much higher birth rate. At the assumed rate of natural increase the population of Australia would double itself every forty-seven years, independent of immigration. He asks what are the advantages of a high birth rate when accompanied, as seems always to be the case in a normal population, with a high infantile death rate.

22. **Dermametropathism.**—In 1902 Lawrence read a paper called "Skin Markings" at the Medical Society of Victoria (see abstract in The Journal, xxxix, Aug. 23, 1902, p. 456) on a new clinical method of diagnosis and exhibited cases. He has since studied the subject and holds to his former opinion that by this method of clinical observation the irritability of tissues in general may, in some diseases, be calculated by the irritability of the tissues of the skin; that certain markings aid the prognosis in certain diseases and may forecast a relapse of the disease and may explain the exaggeration of the symptoms in some individuals; that suitable treatment may perhaps be worked out by observing the effect of treatment on the markings of the skin. He illustrates his ideas with reports of cases of irritating dermatitis, urticaria pigmentosa and scleroderma.

30. **Differential Diagnosis of Human Actinomycosis.**—Poncet reiterates that the centers of human actinomycosis are merely the medical centers where it is better differentiated. He states that 176 cases had been published in France by June, 1903, and 48 have been observed in Paris alone. He thinks that the clinical diagnosis is more apt to be correct than the microscopic, especially when—as often happens—the parasites have withdrawn to inaccessible recesses before encroaching secondary lesions, or been destroyed by the agents of the associated infections. He emphasizes that this affection should occur to the mind as regularly as syphilis and tuberculosis when examining a patient. Every local suppuration of a tenacious, recurring character should be regarded with suspicion, especially chronic fistulous phlegmons suggesting a neoplasm by their hardness, limitation and location on sites particularly affected by these parasites, the face, neck, abdominal wall, iliac fossa, chest, ano-rectal region and, in a much smaller proportion, the limbs. The most striking feature is the association of the characteristics of a cancer with those of an inflammatory lesion. Of course suppuration does not exclude cancer, but the idea of actinomycosis should not be rejected merely from the negative findings of a few microscopic examinations and without having given iodid treatment a chance. He has observed 3 cases in which an old focus of actinomycosis became transformed into a cancer. The ray fungus had been found numerous during the early phase, but after the cancer had been established no more were to be discovered. This form of actinomycotic sarcoma is most frequent on the jaw. In actinomycosis the subjects are generally young, the lesions are not inevitably progressive, the edema, induration and infiltration of the parasite extend far into the surrounding muscle and connective tissue. The infiltration is liable to assume a sclerous consistency, with trismus. The edges of the ulcerations are looser than in cancer, and parts of the edges heal over. The glands are seldom involved, unless from secondary pyogenic infection. The latter is the cause of the impairment of the general health rather than the actinomycosis itself.

32. **Roth Apparatus for Administration of Associated Oxygen and Chloroform.**—Kirmisson relates his experience with this

apparatus, which he regards as a great advance. [Its latest application was in the air-chamber experiments in Germany, mentioned on page 1174.—ED.]

33. **Gravity of Syphilis with Ocular Manifestations.**—Motais has been impressed with the unusual gravity of the tertiary manifestations in cases of syphilis in which eye lesions were observed during the early stages. This exceptional gravity was noted in 52 per cent. out of 82 cases. In the 32 of iritis the tertiary manifestations involved the nerve centers in 15 per cent. and the bones in 20 per cent. In 36 of chorio-retinitis bone lesions occurred in only 2.3 per cent. and brain or spinal in 22 per cent. In the 14 instances of neuritis and atrophy of the optic nerve 5 of the patients have not developed serious manifestations during the three to twelve years since, but bone lesions have been observed in 7 per cent., and brain or spinal lesions in 50 per cent. of the 9 other cases. Fournier thinks that iritis indicates an exceptionally severe fresh syphilis, but doubts whether it presages an unusually grave course later. Motais urges the necessity for prompt and energetic specific treatment of the syphilis in case of eye lesions, with oversight for long after. He found local subconjunctival injections of sublimate a powerful adjuvant in treatment. Hallopeau reported a case of multiple gummatous ulcerations treated by mistake with local applications alone of sublimate, with almost complete healing in three weeks.

34. **Tuberculosis in the Army.**—Kelsch remarks that contagion of tuberculosis between man and man admits of degrees and requires certain conditions for its realization. Far in the lead among these conditions is the consent of the organism to the misdeeds of the bacilli. No other infectious disease can be compared to tuberculosis in respect to the importance of the connivance of the organism. The prophylactic measures in vogue are wise and necessary, but the most solid foundation for prophylaxis of tuberculosis is the development of the physical vigor and the amelioration of social and hygienic conditions. He ascribes the frequent development of tuberculosis among new recruits to the flaring up of some smoldering or almost extinct focus, fanned into a flame by the vicissitudes of army life. New recruits should be taken in during the summer and fall rather than in winter or spring.

38. **Perforated Ulcer of Stomach and Its Drainage.**—Guibal relates that 4 cases of perforation of a stomach ulcer were observed in Tuffier's service in a single year. The first 3 were middle-aged women arriving at the hospital with signs of diffuse purulent peritonitis, the patients unable to answer questions, and incisions on the median line and in the iliac region revealed the pelvis full of pus but the abdominal organs apparently sound. Death followed in less than twelve hours and an undiagnosed perforated ulcer was found in the stomach. The fourth patient was seen early enough for the diagnosis to be made in time from the sudden onset of pain in the epigastrium, the pain and the muscular "defense" following a descending course and predominating in the right side of the abdomen, and the absence of vomiting, with the characteristic attitude and history of stomach trouble during the past two years. The respiration was frequent and of a reversed type, that is, the abdomen subsided during inspiration and protruded during expiration, from paralysis of the diaphragm. The patient promptly recovered after sero-serosa coaptation of the wall of the stomach, drawn together with a Lembert suture. This was preferred to suture of the perforation as the edges were so thin. Guibal ascribes much of the success to his method of draining the peritoneum afterward. Five incisions were made, one in the epigastrium, one in each iliac fossa and a median, suprapubic incision, supplemented by an incision in the posterior cul-de-sac. Each incision was made amply large and a large drain inserted, wrapped in dry aseptic gauze. The incision in the Douglas was the most important as gravity co-operated with capillary attraction to insure copious drainage. Much larger amounts of fluid escaped through this drain and for a longer period than from the other drains. In the case reported fluids still drained away till the fifth day, while the other drains were permanently dry by the third. He has applied these five large incisions for drainage in a number of other cases of diffuse peritonitis and especially the drain in the Douglas, and always with fine results.

39. **Symptoms from Tumors in Motor Region.**—Duret comments on the fact that much the larger number of curative operations on the brain have been in the motor region, 214 out of 344 in his statistics. He reviews here and tabulates 64 cases of tumor in the rolandic or parietal region with special reference to the sensory disturbances in the leg in 12; in the arm or arm and leg in 35, and in the face in 7, with also 10 cases in which the tumor was in the parietal lobule—the sensory disturbances compared for each case with the site and nature of the tumor. He further analyzes the clinical picture of large tumors involving several departments of the motor zone. The vast empire occupied in the brain by the sensory motor zone explains why the tumors developing in it exhibit such a variety of clinical manifestations. The different sensory and motor symptoms presented should be carefully studied not only in themselves but in the date of their appearance, the order of their evolution and their relation to the topography of the cortical centers. It should always be borne in mind that the sensory-motor disturbances may be due to some other origin. Tumors in this region usually develop in several distinct phases, the phases of spasms and convulsions, of paralyses and contractures and of atrophy of the muscles, with sensory disturbances liable throughout. It is a remarkable and encouraging fact that the general troubles may not develop for months or several years or be merely suggested by attacks of headache or convulsions. The diagnosis should be made early, without waiting for the symptomatic procession of the established syndrome. The characteristics of the convulsive attacks, if distinctly localized, should afford grounds for successful surgical intervention. The attack of spasm or convulsion is preceded by a sensory and motor aura, exceptionally, the aura may be mental or consist in sudden and transient aphasia, but generally it is purely motor, a spasm, a tonic or clonic contraction of a small number of muscles, of a finger or toe, or of the tongue or lids. This alarm signal always corresponds to the exact site of the neoplasm in the motor zone. The order in which the convulsive movements occur is typical of the topographic order of the centers in the brain. If there is any irregularity in this order of occurrence it is more probable that the tumor inducing them has only indirect connection with the motor zone, and that it is a question of irritation from a distance.

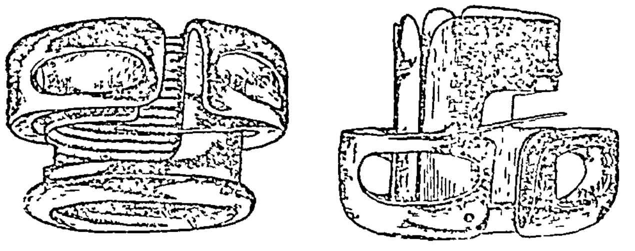
40. **New Theory of Cause of Congenital Dislocation of Hip Joint.**—Le Damany's extensive work presents arguments to sustain the view that congenital dislocation of the hip joint is

due to exaggeration of the strictly human element in the pelvis and femur. These parts have developed anthropologically beyond the present human standard, and such individuals are degenerates not downward but upward.

41. **Metastases from Benign Tumors in Thyroid.**—Colloid tumors in the thyroid gland are liable to induce the formation of metastases which may invade the skeleton or viscera, the skull, jaw, spine, pelvis or limbs having been involved in different cases, although the humerus and femur are the usual sites. The lung is the viscus generally invaded. The metastatic tumor is liable to cause trouble sooner or later even when the thyroid tumor remains constantly latent. Extirpation of these metastatic tumors has generally been a serious operation owing to the lack of delimitation, and recurrence has been noted in some instances. In case the long bones were affected the limb has been sacrificed by some surgeons, but Patel does not think this is advisable, as we can not be sure that the tumor is single, unless one's hand is forced by local trouble. Jaboulay has had a patient cured during the year since he operated for the removal of a metastatic tumor of this kind. The patient was a woman of 65 with a benign goiter and a metastatic tumor at the inner angle of the orbit in the left frontal bone. The goiter had been stationary for thirty years. It was uniformly hard and there were no pains, either spontaneous or on pressure. The ablated tumor revealed parts in which the characteristics of normal thyroid tissue were exactly reproduced, while other parts showed an extremely malignant epithelioma. The particulars of 17 other cases are given as found in the literature of Germany and France. The communication issues from Jaboulay's clinic.

42. **Cancer in Thyroid.**—The special phase of the subject studied in this communication is the invasion of the trachea and esophagus by the cancer. Only 7 instances are known in which the esophagus was actually invaded by the cancer out of 173 cases of cancerous goiter. One is described in detail as personally observed. The cancer developed in this case without preceding goiter, its abrupt onset simulating acute thyroiditis. The particulars of 14 other cases are also cited from the literature.

44. **The Jaboulay-Lumiere Button in Gastroenteroanastomosis.**—Gayet has selected 100 cases out of a larger experience in which this button was used, and extols its advantages. No suture of any kind is required, as it automatically performs its office. The rapidity with which it can be introduced and the anastomosis completed render it particularly valuable in palliative cancer cases "in which even moments count." This button has been in use since 1900, and the mortality in the 100 cases of cancer has been 18 per cent.; during 1902 it was 7.6 per cent., and for six months in 1903 it was only 6.66 per cent. The average survival was seven months, but this includes a number who have shown no signs of recurrence to date. The 100 cases are tabulated. The button does not require any thread thrown around it, as it locks firmly. The slit in the side enables the button to be worked into the viscus through a very narrow opening, on the principle of the cuff buttons inserted by screwing them in.



47. **Topography of Skull and Brain.**—Krönlein's craniometer was described in THE JOURNAL, xxxii, page 312. It has been given a thorough trial at Lyons and the results set forth in this communication are decidedly in favor of it as a simple, easy and inexpensive method of locating the various parts of the fissure of Rolando and of Sylvius. In 25 trials on the cadaver these fissures were exactly located in 14, and in 8 there was variation from the exact location, but never to a distance greater than the diameter of the trephine. Other craniometric methods proved to be much less exact.

52. **Clinical Study of Eclampsia.**—In this communication from the clinic for women's diseases at Zurich the details of 117 cases are tabulated and the postmortem findings in 35 are analyzed. Among the practical conclusions deduced we note the great value of instrumental dilatation in certain cases, also the remarkable predisposition of eclamptic subjects to infectious septic processes. Chloroform was used transiently during the convulsions, sometimes supplemented by chloral per rectum and minute doses of morphin. Inhalation of oxygen proved a valuable adjuvant, especially during the attacks. It seemed to have a favorable influence on the entire syndrome. One patient died in less than two hours after a hot bath. Venesection seemed to have a favorable influence in the 15 cases in which it was used. Bronchopneumonia was found in 6 of the 35 fatal cases, with abscess formation in one case. In some of these cases the lung process was evidently due to food getting into the air passages. The rule should be strictly enforced to give no food to an eclamptic patient by the mouth until consciousness is completely restored. This rule was always observed in the clinic, but the damage had been done before the patients were received. Three of the 35 fatalities were due to sepsis. The eclampsia mortality was thus 27.3 per cent. and in the 90 cases observed during the last decade only the mortality was 23.3 per cent. The mortality of the children was 38 per cent.

56. **Causal Relations of Uterine Myomata and Heart Disease.**—Fleck's article is based on 325 cases of uterine myomata. A heart affection was associated with the condition in 133, that is, in 40.9 per cent. In 46 out of these 133 patients there had been no hemorrhages. At the necropsy of the 12 patients who died in the clinic indications were found which sustain his conviction that a myomatous affection of the uterus is very frequently associated with a degeneration of the heart muscle, which can only be the result of the action of toxic substances. It is sometimes accompanied by a tendency to fatty degeneration, which is probably referable to some anomaly in the metabolic processes. Still more constant is the finding of gross anatomic changes in the ovaries. It is more than probable that these four things are in close mutual relations, and that the tendency to myomatous growths is merely one feature of a general process involving several organs. In all the fatal cases death occurred suddenly, with symptoms of heart failure. In one instance there was embolism in the pulmonary arteries; in 2 others the heart lesions amply ex-

plained the fatality. The others succumbed soon after an operation. In 6 of the fatal cases there had been no bleeding.

58. **Rupture of Cicatrix in Uterus Wall.**—Fellenberg has observed 2 cases of dehiscence of the uterus wall. The rupture was in the cicatrix left from a preceding laparotomy with excision of a wedge from the uterine insertion of one tube. The wall should be sutured in tiers in any intervention on the uterus and the patient should be warned to enter a hospital for future deliveries. Everything should be in readiness for a laparotomy at any moment after labor commences. When such supervision is impossible the birth should be terminated artificially to forestall rupture.

59. **Fate of Children Artificially Delivered Before Term.**—Lorey writes from Halle that the experience there demonstrates that three times as many children are born viable in cases of deformed pelvis when premature delivery is induced in comparison with other cases in which the pregnancy is allowed to go to term. Out of 100 births 74 were born alive, and 60 left the clinic alive, the mortality being thus only 40 per cent., while in 207 previous childbirths of the same women the mortality had been 78.19 per cent. Of the 56 children followed to date, 78.5 per cent. of the 51 legitimate children survived the first year, and 71.5 per cent. of the total number. One of the 83 mothers died of sepsis and 88 per cent. had an afebrile childbed. He advocates induction of premature delivery, but not before the thirty-sixth week, in cases of pelves of 8 to 10 cm. The outlook for the children is good. When the conj. vera is less than 7 cm. artificial delivery should never be attempted. When the birth is long protracted injection of antistreptococcus serum is advisable. In case of sickness of the mother the pregnancy should be interrupted as soon as threatening symptoms are observed. The prognosis for the child is exceptionally bad. In 37 cases in which the mother was suffering from eclampsia, nephritis, heart disease, struma, cancer or cystitis, while 63 per cent. of the children left the clinic alive, only 30 per cent. survived the first year of life.

72. **Hydrotherapy in Lung Affections.**—Brieger is in charge of the Institute of Hydrotherapy connected with the University of Berlin, and he claims that the judicious use of these measures is indispensable in the treatment of tuberculosis. He asserts that routine treatment should be avoided, and this is possible only when the physician himself undertakes or at least supervises the practical application of these physical modes of treatment. Hydrotherapy is a functional therapy, and he has found it accomplish wonders in arousing the resisting powers of the body in various lung affections as he describes in detail. In catarrhal pneumonia the half bath with vigorous friction and pouring cold water on the back of the neck—cautiously applied—form the sovereign remedy, especially valuable for promoting expectoration. The coil of cold tubing over the heart is very useful in croupous pneumonia. Hydriatic treatment will arrest bronchial asthma and prevent its recurrence. The attacks are aborted by reflex stimulation, especially of the skin—extreme temperatures in form of hand or foot baths and douches, or friction to the thorax with hot wet cloths and hot compresses afterward to chest and back. Recurrences are prevented by a systematic course, generally with half baths at about 90 F. and douches at 70 F., Scottish douches and rubbing of the entire body. In one case the attacks increased during menstruation, which impelled him to seek to influence the sympathetic plexus in the abdomen as possibly contributing to the asthma. After a long hot bath he let the water out of the tub and poured cold water from a height on the abdomen, instructing the patient to breathe deep. After a five months' course of treatment with this and other measures the patient, a woman of 41, who had suffered for three years from severe, typical asthma, was completely cured, as likewise a large number of other patients, both men and women. Hydrotherapy hardens the tuberculous patient and enables him to stand the vicissitudes of the home climate. It stimulates the appetite and the patients increase in weight, while they become more resistant to superposed infection and the general health benefits in every way.

74. **Electro-Magnet in Therapeutics.**—Cohn has tested the Konrad apparatus which, with a current of 30 to 40 amperes, induces a magnetism with polarity alternating a hundred times a second. [It has proved very useful in Lilienfeld's hands in an experience with 1,200 subjects.—Ed.] Cohn ascribes the results attained to suggestion only. His experience is limited to 37 cases.

75. **Tuberculin Test Viewed by Light of Recent Research.**—Cornet affirms that later researches have demonstrated that the reaction to tuberculin is a group reaction. It shows that there is some focus where a bacillus belonging to the tubercle group is ensconced, but it affords no information as to whether the bacillus in question is liable to prove dangerous to the existence of the bearer then or later. He expresses amazement that such serious investigators as von Behring, for instance, have allowed themselves to be misled by the Franz and Naegeli statistics and based new hypotheses on them. The positive tuberculin reaction must in future be regarded as in itself no criterion as to possibly progressing tuberculosis. Only in combination with other symptoms pointing to progressing tuberculosis is its testimony of value. Reaction to tuberculin is no proof that the subject requires treatment, and the disappearance of the reaction is no proof that sanatorium treatment has been the cause of the disappearance. The slight amount of benefit now known to be derived from sanatorium treatment in itself must be still further critically sifted. The insignificant anatomic lesions induced by almost entirely avirulent bacilli of the tubercle group—which are yet liable to cause a reaction to tuberculin—are not very important in pathology. The frequency of their occurrence is a question still to be solved.

76. **Paralysis Agitans After Accidents.**—Ruhemann's experience includes 28 cases in which there was no history of trauma out of a total of 35, including 19 women and 16 men. In 13 there had been some emotional shock, in 7 direct trauma. In the others intoxications, over-exertion and organic brain affections were noted in a few, but the rest could not ascribe any cause. A number of the women had suffered from migraine before. The age ranged in the men from 28 to 65, the average about 50, while in women the age ranged from 47 to 70, the average 58. Paralysis agitans is, therefore, liable to develop in elderly subjects without appreciable cause, but in quite a considerable proportion of cases a causal connection between some trauma and the palsy can be unmistakably established. The symptoms developed shortly after the trauma or were markedly aggravated by it. The palsy usually affected the member injured in the accident; otherwise it did not differ from that observed in the non-traumatic cases. When it develops in a comparatively young subject, previously healthy,

the trauma may be regarded as the sole cause. (Compare with Hart's article, page 921.)

93. **Air Chamber to Facilitate Operations in the Thorax.**—In addition to the points previously mentioned in regard to the Sauerbruch air chamber (see page 1174) Mikulicz enumerates among its advantages the access it affords to all organs whose walls encroach on the chest. Extensive resection of ribs during ablation of tumors in the thorax wall, traumatic ruptures and hernia of the diaphragm are robbed of their principal danger. It may be possible to operate directly on the spine from its front aspect, and the possibility of resecting small, circumscribed foci in the lungs has drawn nearer. In operating on the heart we need not fear to open the pleura. From surgical intervention on the heart to restore conditions to normal after some casual injury, it is but a step to intentional interference to relieve certain organic heart defects. He refers especially to mitral stenosis, which he thinks might easily be enlarged by a fine, scissors-like instrument introduced into the ventricle, as *Potter* has already suggested.

94. **Fluorescent Substances.**—Tappeiner claims priority for the suggestion of sensibilizing substances to render them more susceptible to the action of light. (See The Journal, page 806.) He has coined the term photodynamic to express this action, and argues to show that it differs from true sensibilization in several important respects. He warns that erythrosin contains 57.7 per cent. iodin, which excludes it from current use in chronic tuberculous and syphilitic affections. Eosin contains bromin instead of iodin, and is therefore less dangerous while standing next to erythrosin in its optic properties.

95. **The "Scapular Grinding Sound."**—The sound has been likened to that made by a horse chewing oats, although in mild cases it is merely a staccato rubbing sound. It is due to various causes, from lung affections to fracture, and is produced by the rubbing of the scapula against the thorax. Treatment should be addressed to the primal cause.

97. **Chromo-Cystoscopy.**—Voelcker and Joseph describe their experiences to date with cystoscopy after ingestion of a certain amount of some stain. (See The Journal, page 69, paragraph 70.) The findings fully corroborate their preceding announcements as to the great value of this diagnostic measure and its ease and simplicity.

98. **Botryomycosis in Man.**—Frédéric gives an illustration of a lesion on the foot, and remarks that no recurrence has been known after excision of the focus and that the diagnosis is unmistakable after such a lesion has once been seen.

101. *Cancer and Its Treatment.—Hegar concludes* this clinical lecture by expressing his conviction that as general causes unmistakably favor the development of a malignant tumor, the discovery of some successful internal remedy is not without promise. We are unable to prevent old age, but we may be able to postpone senile alterations or at least diminish their influence. He thinks that our knowledge of cancer is already broad and thorough—the final discovery of the specific cause will be merely the last link in the chain. We are already trained in prophylactic measures, avoidance of irritation from pipes, caustics, sharp remains of teeth, etc., removal of warts, cure of cutaneous affections, *ablation of* gall bladder, prevention of stagnation of contents in alimentary canal and cure of erosions at the orifices with restriction of consumption of tobacco and alcohol. There is also the possibility of the discovery of some substance which, injected in sound tissue around the malignant focus, will prevent its spread.

102. **Necrosis of Pancreas.**—In the first of the two cases reported by Hochhaus the affection ran its course completely in nineteen hours and the necropsy two hours after death demonstrated that the necrosis of the gland tissue was the essential and primary factor in the syndrome. There was scarcely any hemorrhage or inflammation. Colon bacilli were found in the pancreas and in the blood in the liver. The patient was a man cook, 39 years old. The second patient was a man of 47, always healthy except for an attack of gallstone colic nearly two years before. He slipped on the lower stone step and fell with his right side on the sharp edge of a step, the trauma causing intense pain in the chest. After lying quietly in bed for a day he felt comparatively well. The third day symptoms of fulminating necrosis of the pancreas developed. The postmortem findings indicated that the trauma had induced a slight hemorrhage in the pancreas and that this in turn had caused necrosis.

103. **Appendix in Ameba Enteritis.**—Hoppe-Seyler warns that greater attention must be paid to the appendix in this condition, and cites a case to show that severe general sepsis is liable to result by way of an altered appendix.

105. **Inherited Syphilis of the Heart.**—Fischer does not know of another instance in which a child with serious hereditary syphilitic lesions in heart and liver lived to be five years old. He also emphasizes the suddenness of the death. Mracek

noted sudden death in 21 out of 58 cases he has collated of unmistakable syphilis of the heart. The findings in the case described were those of a fibrous myocarditis and endocarditis, with a calcified nodule in the right conus arteriosus which might have been the relics of a gumma.

107. **Is There a "Physiologic" Albuminuria?**—Oswald doubts whether we can accept any case of albuminuria as strictly physiologic. He admits, however, that the cases in which there is elimination of euglobulin may have a different prognosis from those in which there is no euglobulin. Further research is needed here.

108. **Adrenalin at the Bedside.**—Voigt writes from Davos that he has witnessed the prompt arrest of threatening hemoptysis in 2 cases after injection of 1 c.c. of a 1/1,000 solution of adrenalin. In both cases there was a marked but transient acceleration of the heart action. He explains its action as inducing—besides the increased heart action—an increased tonicity in the musculature of the vessels, evidenced by the pallor and the hard pulse. This tonicity is displayed most decidedly in the injured region, entailing rigid contraction of the musculature of the bleeding vessels. He urges experiments to determine whether animals after injection of adrenalin bleed less than the controls from a wound made afterward. He was unable to detect any action from administration of the adrenalin by the mouth.

110. **Biologic Blood Test of Mummies.**—Hansemann subjected to the biologic blood test scraps taken from the neck of an Egyptian mummy dating from the first dynasty and thus five thousand years old, also from the mummy of a child dating from the Greek dynasty, two thousand years ago, and also scraps from the leg of a Greek cadaver found in an Egyptian sarcophagus, not embalmed like the others. In every case the modern biologic blood test gave distinctly positive findings.

114. **The Hypnotized Dancer.**—In this communication from von Schrenck-Notzing the particulars of the engagement of the trance dancer mentioned in the news columns, page 1033, are related. She is a professional dancer and came to Munich on invitation of the Psychologic Society, under contract for five private demonstrations, between engagements at the Opera Comique at Paris and in London during May. The lay press made a sensation of her coming, and so many requests and demands were received from private parties and scientific societies for opportunity to see her, that the Psychologic Society, rather than to have her give private demonstrations in the clubs and officers' quarters or elsewhere, chose as the lesser evil to rent a theater and have her performances semi-public. More than 3,000 persons interested in science were bidden free to the performances, but 2,000 others paid high prices for admission, which guaranteed all expenses. Her emotional behavior is on the same plane as the tears shed by Sarah Bernhard and Duse, an ecstasy of autosuggestion, but no one has ever worried over the eventual harm to the nervous systems of the actresses. They take the risks of such performances the same as men who swallow knives or run needles through their tongues. He thinks that the trance dancer with corresponding training outside of the hypnotic state might be able to give fully as remarkable a performance, although different from that of her hystero-hypnosis. Her parents were professionals, a musician and a ballet dancer.

115. **Collargol as a Prophylactic of Septic Processes.**—Camerer practices in a small town, Wertheim a. Main, and its vicinity, and has found inunctions of collargol invaluable as a prophylactic measure. Especially in country practice, where conditions are so unfavorable for asepsis, he has found all menacing complications averted by this simple measure. He prefers to use the collargol in the form of an unguent, as he thinks it is absorbed gradually and evenly over a large surface while this mode of administration is so simple and easy that it does not disturb the patient and it can be safely left to any member of the family. He orders 3 gm. of the Credé unguent to be rubbed into the legs and back alternately, twice a day, the rubbing continued for thirty to forty minutes, until the skin, which is stained black at first, grows a lighter color. He has thus treated 30 parturients, including 3 cases of manual detachment of the placenta, 4 requiring tamponing on account of postpartum hemorrhage, and one case of laceration of the cervix requiring suture. Notwithstanding that the circumstances in these cases invited infection, there was no rise of temperature in any instance.

122. **Treatment of Severe Diabetes.**—Naunyn has long proclaimed that the quantity of the food is of more import than the quality in cases of severe diabetes. He believes that the diabetic needs as many calories as a healthy person, but that for therapeutic purposes it is allowable to reduce the number below the standard. The calories needed may be supplied in fats to supplement the albumin. Usually there is pronounced acidosis in consequence, but if the amount of both albumin and fats is kept down, the sugar in the urine may progressively diminish and finally disappear altogether, and with it the acidosis. Months may be required before this consummation is reached, but that it can be reached is shown by the 2 examples cited. The acidosis was kept under control by large doses of sodium bicarbonate, sufficient to keep the urine alkaline. Both were cases of severe diabetes in young subjects. The first was a young woman with 273 gm. sugar on an unrestricted diet. On a diet of 85 gm. albumin and 215 gm. fat —a total of 2,275 calories—the sugar dropped to 15 gm. a day. Restricting the amount of albumin and fats still lower, to a total of 1,500 calories, equivalent to 28 calories per kilogram, the acidosis began to decline, and with 24 to 27 calories per kilogram both sugar and acidosis had vanished. They returned to a slight extent after indiscretions in diet. The aggravating effect of menstruation was particularly noticeable in this case, as also the return of the menses after long suppression as the patient improved. The acidosis in both cases diminished proportionately much more than corresponded to the restriction of fats. It is evident that it is not proportional to the intake of carbohydrates either directly or the reverse, but the testimony is all in favor of the assumption that it parallels the sinking in the formation of sugar out of albumin. Consequently we are unable to detect any direct influence on the acidosis from the intake of carbohydrates or their suppression, but the acidosis is manifestly dependent on the tolerance. The tolerance was increased in these 2 cases, however, not by suppression of the carbohydrates alone, but by simultaneous restriction of the albumin and fat in the food.

124. **Serum Treatment of Articular Rheumatism.**—Schaefer treated 6 cases of articular rheumatism in adults and children with Menzer's antistreptococcus serum, with the best

results. The attacks were much shortened and the health afterward unusually good. No by-effects were noticed.

125. **Treatment of Myxedema.**—Magnus-Levy draws the picture of myxedema and sporadic cretinism with special reference to the frequently unrecognized indefinite forms, the "formes frustes." Thyroid treatment is liable to prove effectual even in very old and inveterate cases. Unpleasant surprises sometimes occur, which he thinks are usually due to having overshot the mark and induced hyperfunction in the thyroid gland. There is no testimony as yet in favor of the cure of endemic cretinism by this means, but it is not impossible. When patients begin to improve the persistence and progress of the improvement depend on the continued application of the thyroid treatment.

126. **Cypress Oil in Whooping Cough.**—Bravo poured a few drops of cypress oil on the clothes and pillows of children with whooping cough and reported remarkably fine results from its use. Soltmann corroborates his testimony and reports here the clinical histories of 19 cases of pertussis treated in this way. The number of paroxysms was promptly and rapidly diminished, and they were much shorter and less intense, the intervals were longer and the debilitating aftereffects much reduced. The influence of the remedy was most apparent when it was suspended for a time and then resumed, its effect on the paroxysms being unmistakably evident. He used a 1/5 alcoholic solution of the oil and poured 10 to 15 gm. on the pillow, upper part of the bed and the underclothes of the child, repeating this four times a day. The only drawback was that the oil left stains on the linen.

129. **Thiosinamin to Soften Cicatricial Tissue.**—Lewandowski remarks that he has been overwhelmed with questions as to the action of thiosinamin since his publications on the subject. He states comprehensively in reply that it is immaterial how long the cicatrix has existed for it to be amenable to thiosinamin, except that possibly it is better to wait a while in case of recently-formed scar tissue. He has been successful with cicatrices thirty years old. He prefers the subcutaneous mode of administration and states that no one has reported any ill effects of any kind from its use. The injection does not have to be made in the vicinity of the cicatrix. The thiosinamin works through the blood, and the site of injection is immaterial. He describes a case recently observed in which synechia of the iris required instillation of homatropin—the subject a lad with scarlet fever and diphtheria, the disturbance in the left eye having much reduced the vision. Thiosinamin was injected subcutaneously at the same time that the homatropin was instilled and it had an unmistakably favorable action, evidently softening and preparing the soil for the homatropin to work on. See title 116 above, and also pages 805 and 1111.

138. **Perforation of Tubal Pregnancy into Bladder.**—Matto describes a case which had been previously and perseveringly treated on the assumption of urinary calculi, as the patient, a multipara of 35, complained of distress and the sensation of foreign bodies in the bladder. Instrumental examination disclosed a bone, supposed to be that of a chicken at first, but further investigation showed the bladder to be nearly full of bones. The patient six years before had passed through what was assumed to be a six-month abortion, and intrauterine douches had been applied. The menses had been regular since and there had been no symptoms except the presence of a small, hard tumor in the right side and the supposed "urinary calculi." Nearly the entire skeleton of a fetus almost at term was removed piece by piece from the bladder, the missing bones probably having passed and been accepted as calculi, until she began to experience great pain in the region of the tumor, with vomiting, and the urine became dark red and terribly fetid. Alkalines and lithia salts had been prescribed until the discovery of the bones. Six years had evidently elapsed between the tubal abortion and the perforation into the bladder, and the presence of the decomposing fetus had caused no appreciable symptoms during this interval. The tolerance of the bladder for the foreign bodies was also remarkable. The bones first passed and assumed to be urinary calculi had been examined by a druggist—not by a physician—which explains their non-recognition. Matto adds in conclusion a somewhat similar case related in the *Mercurio Peruano* more than a century ago. The patient was a girl of 16 who had aborted in consequence of pounding her abdomen against a door in a passion. The fetus could be palpated from without, but the physician found the foot projecting from the urethra. The entire leg came with the foot, the next day the other leg, five days later other bones were voided and this continued, a few bones at a time, for several weeks. Two or three years later the skull presented and was extracted, but caused such traumatism that there was incontinence of urine thereafter.

141 and 143. **Tubercle Bacilli and the Tonsils.**—Escomel regards the tonsils as the most tuberculizable organs of the entire alimentary canal. He has found tubercle bacilli in them even in healthy subjects, and thinks that tuberculous infection of these organs is frequent and extremely easy, while the diagnosis is difficult. The infection is generally exogenic, but once installed the general lymphatic system is liable to become invaded and no one can say where the infection will end.

Original Articles.

INTESTINAL PERFORATION IN TYPHOID FEVER.

BYRON B. DAVIS, A.B., M.D.
Professor of Principles of Surgery and Clinical Surgery, College of Medicine, University of Nebraska; Surgeon to Immanuel and Wise Memorial Hospitals, etc.
OMAHA.

According to Hugh M. Taylor, 50,000 to 75,000 deaths occur annually in the United States from typhoid fever. If this is correct, and if we accept Osler's statement that one-third of these deaths are due to intestinal perforation, we have, at the lowest estimate, 16,666 deaths annually in the United States due to typhoid perforation. Again, accepting the opinion of Osler, Finney and others who have had the most experience with this condition, that one-half of these lives might be saved by timely operation, we have a grand total of 8,333 persons annually whose lives might be saved by timely surgical intervention. The average age of those dying from typhoid fever is 28.8 years, the greater number being males, most of them the heads of families. If, by carrying out the ideal treatment, 8,333 persons in the most valuable period of life might be saved to their families and to the state every year, the subject assumes an importance not to be ignored.

Considering the rapid progress of abdominal surgery during the last fifteen years, the medical profession has been strangely apathetic in realizing the value of the surgical treatment of intestinal perforation occurring in the course of typhoid fever, first formally suggested by Prof. E. Leyden, an internist of Berlin, in 1884, almost twenty years ago. In 1887, Lucke of Germany and Bontecou of Troy, N. Y., each without the knowledge of the other's work, adopted Leyden's suggestion, but neither of their patients recovered. These were the first cases operated on in which the definite diagnosis of typhoid perforation was made before the operation, though the honor of the first successful case must be given to Mikulicz, who operated in 1884, the diagnosis of typhoid fever not being made until after the operation.

Why have surgeons as well as internists been so slow in employing operative measures for this emergency? In the first place, the widespread opinion that typhoid patients can not stand anesthetics or major-surgical operations, has been an important factor against the general adoption of this procedure. The best answer to a fancy is a fact. The great mass of the profession shook their heads, a few venturesome ones operated, and it was discovered that patients in the midst of typhoid do stand operation remarkably well, and as the time of the operation does not extend beyond twenty or thirty minutes, the deaths from shock are very few. Many of the subjects of perforation are in fairly good physical condition, since it seems to occur in the mild cases relatively as frequently as in the more severe, and is quite a common occurrence after convalescence is well established, being due many times, I believe, to too early increase in the diet.

Another circumstance which has contributed much to cast a doubt on the value of surgical intervention, has been the fact that a large proportion of the operations have been undertaken for general peritonitis—not for mere intestinal perforation. If we had continued to hold our appendicitis cases till general peritonitis was present before operating, the present low mortality for appendicitis would not have been reached. It is my opinion that symptomatology of typhoid perforation as given in our text-books is often much more nearly the symptomatology of general peritonitis than mere perforation. The whole trend of modern surgery in other lesions is to put out the incipient blaze before the general conflagration has begun. Shall we make an exception in typhoid perforations? Before the ideal results are reached, the rules made use of in other acute surgical diseases must obtain, and operations be done as a routine for typhoid perforation, not for general peritonitis.

When it is considered that a very large number of the operations thus far reported for typhoid fever have not been done until general peritonitis has been fully established, 50 per cent. of recovery does not seem unreasonable, if done before the advent of peritonitis. The latest statistics from Johns Hopkins give 41 per cent. of recoveries. There they are striving to operate for the perforation merely, but even there several cases are recorded with a fully developed peritonitis. Another point affecting the mortality is that a small per cent. of the patients dying after operation do not die from the operation or the perforation, but as a result of the general typhoid infection. Such cases should not be charged against the operation.

The length of time intervening between the perforation and the moment of operation will tell us much regarding the difference in the mortality between operations for mere perforation and for general peritonitis. Armstrong, in a paper before the Chicago Surgical Society in May, 1902, reports 33 cases of typhoid perforation operated on in Montreal; 10 were done within twelve hours after perforation, with 4 recoveries, 40 per cent.; 10 were done from twelve to twenty-four hours after perforation, with 1 recovery, 10 per cent.; 5 were done from twenty-four to sixty hours after perforation, with no recovery; 1 was done seven days after perforation, with recovery. The last consisted merely of opening a circumscribed abscess. Even the 20 cases in Montreal, operated on within twenty-four hours, with a mortality of 75 per cent., undoubtedly include a number of cases of general peritonitis, for, in many instances, peritonitis is developed within two to four hours after the moment of perforation.

The table made by Keen in 1900, showing the time of operation after perforation had occurred in the 158 cases recorded by him, seems to throw a doubt on the value of very early operation.

Under twelve hours, 29 died, 7 recovered, or 19.44 per cent.; twelve to twenty-four hours, 27 died, 12 recovered, or 30.76 per cent. Keen thinks the greater mortality during the first twelve hours is due to shock.

It occurs to me that this argument for operative delay is more apparent than real. In the first place, those who are very ill, in a stupor, are much less likely to show symptoms of perforation, and the first indication of the calamity is the advent of general peritonitis. It is more than probable that several among those operated on during the first twelve hours belonged to this class. It is also true that when the perforation is large and the fecal leakage extensive, serious symptoms develop immediately, and the earlier operation is likely to be done, the mortality in this class of cases being higher than among those with minute perforations and little or no extravasation of the bowel contents. Again, some patients are very susceptible to peritoneal irritation, and show marked symptoms from the first, these being very unfavorable subjects for operation. Still further, when for any reason, avoidable or unavoidable, the operation has been postponed, the patients very ill from the disease, those with very large perforations and those who succumb easily to peritoneal irritation, are likely to be moribund or nearly so after twelve hours, and die without an operation.

On the other hand, those operated on during the second twelve hours are likely to be the cases not so very ill from the disease—those with minute perforations and slight leakage or none at all—and those especially unsusceptible to peritoneal irritation. I am convinced that those operated on during the second twelve hours very largely included cases of this kind, and were in every way the better subjects for operation. Not for a moment do I believe that the mortality of Keen's 39 cases operated on from twelve to twenty-four hours after the perforation, would have been greater had they been operated on during the first twelve hours. On the contrary, I believe that several of those who died might have been saved.

The question of whether or not to operate during the existence of shock has been variously answered by different observers. As might be expected, Keen takes the view that the operation should be done "at the earliest possible moment, only waiting until the primary shock, if present, has passed away." Robert Abbe says: "Operations for perforation should be delayed until shock has passed, say within twelve to eighteen hours."

Most authorities I have been able to consult do not wait for shock to pass away, feeling it is better to run some risk from immediate death rather than a greater risk from a general peritonitis. Cushing says the only contraindication to the operation is a moribund condition of the patient. G. G. Davis states that operation should be done at once, even in collapse, rather than wait for severer collapse later on. Armstrong says that when shock is most pronounced is when a large perforation is present with much fecal leakage, and we should not wait for reaction. My own opinion is that if shock is prolonged beyond the time necessary to prepare for operation, the spreading infection of the peritoneum is more dangerous than the operation; that in cases of severe shock, if we wait for a favorable time for operation, we will not operate at all. I would rather operate for perforation without general peritonitis during shock, than for general peritonitis without shock. If we ever expect to reach ideal results in the treatment of typhoid perforation, we shall have to make a practice of operating at once, whether shock is present or not, having everything done possible by all known methods to counteract shock while we work, doing the operation in the shortest possible time and with the least possible amount of anesthetic.

DIAGNOSIS.

The diagnosis of intestinal perforation is not always as easy as the reading of our text-books would lead one to suppose. The keenest observers have failed to recognize it, and have operated for supposed perforation when no such condition existed. Many diagnoses of perforation have been made from the symptoms of general peritonitis, symptoms which might have led to the diagnosis of perforation several hours earlier having been disregarded. The symptoms of perforation are not always violent. Often they are so slight as not to give the alarm. The patient may complain to his nurse of abdominal pain, and be given a hypodermic of morphin, which masks the symptoms effectually until the advent of general peritonitis.

In my own limited experience, the most marked symptoms have been abdominal pain, localized tenderness, thoracic breathing and muscular rigidity. Sudden decline of temperature and the phenomena of shock have not been so constant.

Pain.—Sudden complaint of severe abdominal pain, which persists, should be considered a danger signal. The location of the pain is variable, but is most often manifest in the umbilical region. Sudden increase of pain which has been present as part of the disease is to be regarded as equally significant.

Tenderness.—Still more important is fixed local tenderness usually below the level of the umbilicus and oftenest to the right of the median line.

Thoracic Breathing.—Because of the pain, abdominal respiration is less marked than normally, and the respiration is of the thoracic type.

Muscular Rigidity.—The pain, tenderness and thoracic respiration were present in the three cases reported, but the muscular rigidity present in Case 1, extremely marked in Case 2, was so slight in Case 3 that I was in doubt about the diagnosis. It is, however, a sign of great value, and I believe it to be almost always present, greatest in the region of the perforation.

Shock.—Apparently this is not always present, though a subnormal temperature was observed in two of my cases, not noted in the other. I am convinced that if looked for at the proper time, a small reduction of temperature would be found in most cases. If the patient is not too ill, there is also a feeling of anxiety or impending calamity, often eloquently expressed in the countenance. Chill may or may not be present; also nausea and vomiting occasionally occur, though this is more often an ushering in of general peritonitis. The pulse, if there be much shock, becomes somewhat compressible, followed by an increase in rate.

Obliteration of Liver Dullness.—This is not a frequent phenomenon, and when it occurs may be due to other causes than free gas in the abdominal cavity, as the pushing up of the liver by coils of distended intestines.

Leucocytosis.—This is a sign on which little reliance can be placed. Sometimes it is present, sometimes there is even a reduction in the number of leucocytes. Cabot, in "Clinical Examination of the Blood," says on this point: "It is probable that slight local peritonitis always produces leucocytosis unless the individual is already in a condition of profound general septicemia. On the other hand, a sudden (general) infection of the peritoneum with large quantities of excessively malignant organisms may often result in complete absence of leucocytosis, or a relatively slight rise, followed later by a fall." I think we must conclude with Harte that "the leucocyte count has proven of very little value at the time most needed."

Blood Pressure.—George W. Crile is of the opinion that a sudden rise in blood pressure is an indication of typhoid perforation. In four cases this fact was verified by operation or autopsy. If verified by more extensive observation, this may prove a valuable sign in cases of difficult diagnosis.

Red blood count and estimate of hemoglobin in case differentiation between perforation and hemorrhage is difficult, would doubtless be of much value, as pointed out by Briggs.

The preceding signs and symptoms are many of them present in perforation. The symptoms of the consecutive peritonitis are the usual symptoms of general peritonitis, whatever be its cause, and need not be considered here.

TREATMENT.

How can the ideal method of treatment, early operation for intestinal perforation before general peritonitis comes on, be realized? If every physician, whenever he has a case of typhoid fever, were to keep constantly in mind the possibility of perforation and be prepared for its prompt surgical treatment, a long stride in advance would be accomplished.

The duty of a surgeon, when called to such a case, is, first, to be prompt. If the diagnosis of perforation is fairly certain, immediate operation should be done. The family should be informed of the condition of affairs in a way to convince, and the necessity of avoiding delay should be insisted on. Transportation to a hospital is likely to increase the leakage and disseminate infection. Therefore, the operation should be done in the house where the perforation occurs.

There is another class of cases in which absolute diagnosis of perforation is impossible. The line of procedure in such a case is not so positive. Even here the dictum of Cushing, "when reasonably in doubt, explore," is the safest rule to follow. In doubtful cases, Osler believes in giving the patient the benefit of the doubt and operating. Richardson expresses the opinion that operation should be done "when the perforation is suspected rather than demonstrated." Several operations have already been done and no perforation found, no ill consequences resulting. The symptoms in some of these cases have been demonstrated to be peritoneal irritation or infection from an ulcer about to perforate, and several observers, notably Finney, Cushing, Keen and Briggs, have attempted to formulate the symptoms of this so-called pre-perforative stage, with the view of anticipating perforation by operation. Although not denying that in rare cases such refinement in diagnosis may be reached, I believe that usually it will prove chimerical. Peritonitis may arise without perforation, just as a perforation of the appendix is unnecessary to produce a local or even a general peritonitis, but to call this a pre-perforative stage is not correct and not borne out by the facts, for perforation might never occur in such a condition. Operation for a non-perforative peritonitis is undoubtedly good practice. I only object to the use of the term "pre-perforative stage."

When the surgeon calls and finds general peritonitis already developed, it is unquestionably his duty, if patient is not moribund, to operate, for some of these cases can be saved by this means. Murphy has reported 6 successive cases of general suppurative peritonitis, one of them due to typhoid perforation, all of them recovering after operation. Although our duty is clear to do all in our power to save the cases of general peritonitis by the most radical procedure called for, these cases should not be classed as deaths from typhoid perforation. Our whole effort may reasonably be directed to anticipating the general peritonitis by operation for the perforation before infection begins.

The technic of operation is not a fruitful subject for discussion. There seems little disagreement in regard to technic, all the trouble seeming to arise from the lateness in which the procedure is made use of.

The best incision is doubtless along the right semilunaris or through the outer border of the right rectus muscle. The cecum and appendix are first found and inspected, and then careful search is made along the lower three feet of the ileum where the perforation, if present, is found in most instances. The next most likely place to find the perforation is in the sigmoid flexure. The size of the perforation varies from a pin point to a ragged hole encompassing half the circumference of the ileum, as in my second case. In about 35 per cent. of the cases, the perforation is single.

To close the perforation, fine silk is used, with a Halstead mattress suture or a running suture, the direction in which the stitch is passed being parallel with the bowel so as to encroach as little as possible on the lumen. No paring of the edges of the opening is called for, simply infolding being sufficient. If several perforations are present—crowded together—I doubt whether resection is ever justifiable, this being too formidable an operation for the patient to bear. In such a case the loop may be pulled up into the wound and an artificial anus established, or gauze may be packed about the loop containing the perforation and complete sequestration of the point of leakage made from the rest of the abdominal cavity.

Enterostomy has been formally proposed as a substitute for suture of the perforation, and the results in the few cases reported by this method are so favorable that it deserves further investigation. Escher of the Trieste City Hospital, in Austria, reports four operations made by this method, with three recoveries, and has collected ten other cases treated by enterostomy, with four recoveries. This makes fourteen operations with seven recoveries, the ideal result we are striving to reach. Where much gas is present especially, this procedure would look promising, quickly doing away with the excess of gas. The artificial opening can later be remedied by a simple operation.

After disposing of the perforation, the extravasated bowel contents must be removed from the peritoneal cavity. If only a slight amount is present, and localized near the perforation, I would use no irrigation, fearing to spread the infective material broadcast through the abdomen. In this condition, careful wiping out of the fecal matter will suffice. On the other hand, where the leakage has been extensive and has become scattered, copious irrigations with normal salt solution are most effective, directing the point of the irrigator to all parts of the cavity, giving especial care to the pelvis and flanks. When all seems clear, thorough drainage tubes and large cigarette drains are used, here also being careful that the pelvis and flanks are thoroughly drained. There may be cases where drainage is not required, but it can scarcely be dispensed with unless the amount of leakage has been practically *nil* and the operation has been done at a very early hour.

The operation should be carried out as expeditiously as possible, bearing in mind that the patient is in no condition to endure a prolonged operation. Every effort should be made to overcome shock, if already present, or to avoid it.

Much has been said regarding local anesthesia in these cases, but I doubt the wisdom of operating without a general anesthetic. The shock from the pain and nervousness and fright will, in most cases, be greater than the shock from a general anesthetic. Furthermore, under local anesthesia, the operation takes longer and is not likely to be as thorough.

My own choice in this matter is to use ether by the drop method, make the incision and search for the perforation quickly, and as soon as the perforation or perforations are found, stop the anesthetic, the closure of the perforation and the peritoneal toilette giving very little pain, and usually they will be completed before the patient regains much sensitiveness.

I shall not consume your time by a consideration of the treatment of general peritonitis due to perforation, since the same conditions hold here as in peritonitis due to other causes.

Case 1.—Male, aged 17 years, in the third week of typhoid fever, three other members of his family being down with typical typhoid, was brought to Immanuel Hospital from his home in Florence, Neb., June 29, 1895, with a history of having been progressing favorably till two days before, when he was suddenly seized with intense pain in the right lower abdomen, which had continued since that time, abdominal distention increasing.

Condition on admission: Temperature, 103.5; pulse, 140; thoracic breathing and great abdominal distention. Tenderness everywhere, but greatest in right lower quadrant. Immediate operation. Incision in right semilunaris. General suppurative peritonitis present with a large perforation of the appendix. Appendix removed, there being few adhesions, abdominal cavity thoroughly flushed and drained with gauze and rubber drainage tubes. Ether anesthesia. Patient apparently rallied fairly well, but in a few hours began to fail, and died twenty-four hours after the operation.

The appendix was submitted to Dr. W. R. Lavender, professor of pathology in Omaha Medical College, who stated that he found the bacillus typhosis and pronounced it a true typhoidal perforation, due to ulceration of a solitary follicle.

Case 2.—Male, aged 22. At 4 a. m., Nov. 7, 1902, I reached a farm house four miles from Central City, Neb., where I had been summoned by the Drs. Benton to see a case of intestinal perforation occurring early in the third week of typhoid fever. He had been very ill, but with no alarming symptoms till 2 a. m., November 6, when a sudden intense pain occurred just below the umbilicus, which persisted, and Dr. J. E. Benton was called. He found the temperature 97 F., pulse 110, abdominal tenderness marked just below umbilicus and to the right of the median line. Considerable rigidity of the right rectus muscle. Not improving by afternoon, I was summoned.

Condition at time of my visit: Temperature, 102; pulse, 112; the most intense rigidity of abdominal muscles it has ever been my fortune to observe. Abdominal respiration seemed entirely suspended, his respiration being of the thoracic type. Still complaining of pain, but not so intense. General abdominal tenderness, but most intense near the McBurney point. His countenance did not have the expression of such acute illness as would be expected from his other symptoms.

Operation was immediate, by incision through the outer border of the right rectus muscle. Large quantities of fecal material were free in the abdominal cavity. A large perforation was found in the ileum about two feet from the ileocecal valve. It was very ragged and large enough for one to have inserted two fingers, and included one-half the circumference of the bowel. By a hasty suture the leak was closed. Next a large quantity of normal salt solution was used for irrigation. It was estimated that a quart of feces was washed out of the pelvis. General peritonitis was present. Thorough drainage used. Returned to bed apparently none the worse from the operation, but he sank and died twenty-four hours after the operation. No leucocyte count was made.

Case 3.—Male, 19 years. Was seen at the South Omaha Hospital in consultation with Dr. Curtis, Dec. 15, 1902. The young man had been ill with typhoid fever, as nearly as could be estimated, about two weeks. December 12 he had had an intestinal hemorrhage, which had depressed him greatly. A few hours after the hemorrhage a blood count had been made, showing 9,000 leucocytes. After the hemorrhage he progressed fairly well, the temperature ranging from 101 to 103.5 degrees till about 7 a. m., December 15, when he complained of abdominal pain, but not so marked as in Cases 1 and 2. His temperature dropped to 97.4 degrees just after the complaint of pain, but rapidly rose again.

When seen by me, about eight hours after the symptoms of abdominal pain began, his temperature was 102 degrees, pulse soft and 116 per minute. Respiration not hurried, slight abdominal distention, almost no rigidity of the abdomen, some tenderness in right lower quadrant, but not marked. Leucocyte count showed 11,000; no vomiting. Considering the absence of abdominal rigidity, the slight amount of pain and tenderness, and the history of the previous hemorrhage, I could not feel fully convinced that a perforation was present. No operation was done.

Gradual increase in pulse rate and death occurred thirty-six hours after the onset of the abdominal pain. An incomplete autopsy showed a perforation approximately thirty-six inches from the ileocecal valve.

In this case I think that frequent estimation of the hemoglobin and a red blood cell count might have been of material value, differentiating between intestinal perforation and hemorrhage.

THE OPERATIVE TREATMENT OF ECLAMPSIA.

CHARLES SUMNER BACON, M.D.
CHICAGO.

In threatened eclampsia before the outbreak of convulsions operative interference is sometimes necessary. The indications for such interference may be either maternal or fetal. If in the later months of pregnancy well-known symptoms of intoxication occur that arise from the pathologic condition characteristic of eclampsia, and if these symptoms persist in spite of diet and the use of eliminants like purgatives and diaphoretics and other appropriate treatment, the termination of pregnancy may become necessary. While not entering into a discussion of this indication more in detail, I will say that it should receive greater attention than is ordinarily given it. I do not believe that the emptying of the uterus is often required, for I think that radical appropriate treatment, and most important of all, rest in bed, will generally tide the patient over the dangerous period, yet certain cases will arise, especially when the eyes are involved or when there is much distension of the uterus, where operation will be the only way to prevent convulsions.

It is well established that the fetus often suffers from an eclamptogenic intoxication. Pathologic anatomic changes occur in the liver, kidney, brain, etc., similar to those found in the mother. This is probably the reason why there is such a large number of stillbirths from eclamptic mothers, and why so many children die during the first days of life. It might seem reasonable to hope that a child removed at thirty-five to thirty-six weeks would be in better condition than one exposed longer to deleterious influences of the maternal poison. Moreover, if a child could be safely removed at this time it might escape the danger of a hasty operative delivery. This consideration, while not furnishing an independent indication for labor, may be of supplementary value in making a decision when the condition of the mother is such as to excite apprehension.

If termination of pregnancy is decided on, two methods should be considered: (*a*) the induction of labor, and (*b*) the removal of the child by cesarean section.

The principle that should determine the method of inducing labor for threatened eclampsia is to choose the operation that will least disturb the patient. It is not unlikely that the disturbance of labor is frequently the immediate exciting cause that brings on a convulsion. Hence one should avoid any operation that might have the effect of a prolonged and severe labor.

In accordance with this rule in cases of hydramnion, twins or other conditions where the patient suffers on account of abdominal distension, one would bring on labor by rupturing the membranes. In other cases the Krause method of using a bougie, if properly employed, is efficient, safe, reasonably prompt and causes no more disturbance than normal labor. The bag or manual dilatation of the cervix is not often needed, and while by its use labor can be completed in much shorter time, it disturbs the patient much more and requires sometimes long-continued anesthesia.

The proposition to remove the child in these cases by opening the uterus is a new one, but one that promises several interesting advantages over the induction of labor in certain cases. The danger of convulsions occurring during induced labor is avoided. Other dangers not as yet fully recognized, like the production of organic lesions of the liver and kidneys and myocardium, are present in case of any labor in an eclamptic woman. These would be avoided also by such an operation. Moreover, the chances of the child are, of course, improved in this way.

An abdominal cesarean section would be employed in case of some obstruction in the pelvic obstetrical passage, like contracted pelvis, etc. Otherwise the new operation of vaginal cesarean section would be performed, because it is attended with less shock and leaves no external scar.

I have recently reported a case of this kind that well illustrates the points just made. In brief, the case was as follows: The patient had severe convulsions in her first labor, which led to the birth of a dead child. Four years later, during the latter half of her second pregnancy, symptoms of severe eclamptogenic intoxication appeared. In spite of rigorous treatment, the albumin increased to 35 per cent. by examination with the centrifuge, headache became very severe and vision very greatly impaired. I had hoped to carry the pregnancy to the thirty-fifth week on account of the child, but the appearance of the eye symptoms and the urgent advice of the consulting ophthalmologist who represented that continuance of pregnancy involved great risk of permanent loss of vision, led both Dr. Frank B. Earle, who was associated with me in the case, and myself to decide on interference in the thirty-first week. For reasons given above, vaginal cesarean section was chosen, and the child delivered in fair condition. Although it was placed in an incubator and well cared for, it lived only about forty hours. The condition of the mother began to improve a few days after the operation, and at the end of two months she was in a fair state of health.

After the occurrence of convulsions, rapid operative delivery is indicated when possible, i. e., when it does not in itself involve greater danger than that presented by the eclamptic condition. While in perhaps one-third of all antepartum or intrapartum cases convulsions do not cease immediately after delivery, and in 20 to 25 per cent. of all cases they first appear in the puerperium, yet as the disease is due to the connection of the egg with the maternal organism, it is desirable to separate it as soon as possible. It is also true that in hospitals where active interference has been instituted the mortality from this affection has diminished. In other words, the clinical results prove that proper interference is beneficial. Moreover, the hope of saving the child may have some influence in deciding on the operation.

In order to achieve the hoped-for results from operative interference, it is necessary that the best facilities for performing such operation be secured.

For any of the operations included under the term accouchement forcé, it is necessary that the operator have a table, good light, necessary instruments, assistants, aseptic preparation and the requisite skill. All these essential conditions can be obtained much better in a hospital, and it is therefore desirable to secure the advantages of a hospital whenever possible. The danger of transporting a patient two or three miles is not to be overlooked, but it is more than counterbalanced by the facilities for good work.

The contraindications to operation, when the patient is not moribund, is found in the absence of or impossibility to secure the necessary facilities. It is safer to combat the dangerous symptoms with morphin and promote elimination by purgatives and sweating and perhaps bleeding, than to attempt dangerous operations with an uneffaced and undilated cervix without proper conditions.

All operations should be made under complete anesthesia. The good results now obtained from active operative therapeutics are due in great part to the general observance of this rule. Without anesthesia painful manipulations are apt to bring on convulsions, and in any event the struggles of the patient and the shock to which she is exposed have a deleterious effect on her strength, and especially on the already overburdened and weakened heart. Before the general use of anesthesia in these cases, operation often hastened the fatal issue, and so came into disrepute, from which they have only emerged within the last ten to fifteen years.

The choice of the anesthetic is in dispute. I believe that ether is preferable to chloroform. Some give preference to *chloroform*, because in eclampsia, where there is almost always kidney disease, they believe chloroform less injurious. The statement that ether is more dangerous than chloroform in kidney disease has been passed along from one writer to another, but as in many similar instances, very few have taken pains to confirm it by personal experiment or careful and sufficient study. Lately a number who have studied the subject have come to doubt the statement, and I believe it should not be given much, if any, weight. On the other hand, the much greater safety of ether in case of heartstrain and exhaustion makes it especially indicated in eclamptic cases. Lesions of the myocardium are found very frequently in postmortem examination of patients dying from the disease, and may be considered one of its characteristic pathologic changes. This diseased heart is put to greatly increased strain during a convulsion. It is evident that the anesthetic that works the least harm to the heart should be chosen for an operation, and I feel confident that ether will always serve us best.

The remarks concerning an anesthetic apply only to that used for operation and not to an anesthetic to control convulsions. I believe that anesthetics have no place here; that morphin is much safer, and that the frequent, long-continued use of chloroform for this purpose is very bad practice.

To consider now the operative means to be employed in different conditions antepartum and intrapartum, we may begin with that condition about which there is no difference of opinion, namely, when the cervix is completely dilated. Here all are agreed that the child should be delivered immediately, or as soon as the patient can be anesthetized and preparations made for the operation. In case of head presentation forceps will be used and in a breech manual extraction will be employed. If there be obstruction in the passage due to contracted pelvis or a tumor, or if the passenger be abnormally large or deformed, the case will be managed in accordance with the rules that apply to the management of dystocia.

When the cervix is effaced, but only slightly or partially dilated, we have a condition where our facilities for work may influence our procedure. We have the three methods of dilatation—incision, digital and bag dilatation. The first is accomplished in a moment and allows immediate extraction. It, however, requires good assistance for its proper execution and for the repairs that are quite likely to be needed. Hence it should only be attempted in a hospital or where equally good conditions can be secured.

All preparations for the operation, for repairs and for control of hemorrhage having been made, the patient is placed anesthetized on a table in a good light and large retractors inserted in the vagina to expose the cervix. The posterior lip is first caught with two artery or vulsellum forceps each side of the median line, and then cut through to the vaginal junction with long angular scissors. The anterior lip is then held and incised in the same way. This prepares the cervix for forceps or turning and extraction. The greatest danger is due to the unprepared state of the vagina, which, in primiparæ, is apt to be badly torn during the forcible delivery. If this danger can be minimized or the injury well repaired, this operation may promise the best results for mother and child.

Where assistants and other facilities are lacking, we must rely on digital dilatation or metreurysis, or both combined. For these operations the patient should also be anesthetized, shaved and cleaned and placed on the table. Digital dilatation may be effected by using the fingers of one hand according to the method of Harris or by the fingers of both hands, according to the Edgar method. In the first case the hand is very carefully sterilized and perhaps covered with a glove, and the half hand introduced into the vagina. The forefinger is then pushed through the os. It may be necessary to make a preliminary dilatation with a branch dilator. The forefinger is withdrawn to its tip and the second finger inserted along beside it. After these are carried through the os the distance of one to two inches they are separated as far as possible. They are then withdrawn and the third finger added to the other two. After separation and dilatation, as before, the fourth finger is added and dilatation completed as far as possible. Then the whole hand is carried into the vagina, and the thumb with the fingers pushed through the os to the metacarpophalangeal articulations and the fist closed. The average fist measures about 27 cm. in circumference, which is about three-fourths of the circumference of the average fetal head.

By the Edgar method, after introducing the forefinger of one hand the corresponding finger of the other hand is inserted and the os pulled open as in dilating the sphincter ani in an operation for hemorrhoids. Later two or more fingers of each hand may be used in the same way.

By neither of these methods is the cervix opened completely as in normal labor. The tissue is not pulled up into the lower uterine segment, and a rim remains that is liable to tear during extraction. However, if one can take time to complete the dilatation as well as possible, extraction may be made without great risk. The time required will vary greatly, depending on the amount of the spontaneous dilatation that exists at the beginning and the thickness and distensibility of the cervical tissue. In favorable cases one may succeed in fifteen to thirty minutes, while frequently one to two hours or more may be required.

The metreurynter or uterine bag opens the cervix in a way more nearly approaching the normal, but its use requires the help of one more assistant. The conical, inelastic, vulcanized bags of Voorhees are most to be recommended. With the patient in position as before described, the cervix is seized with a vulsellum forceps, which is held in the left hand. The right half hand is then introduced into the vagina, the forefinger carried through the os and the membranes ruptured. Then the empty folded bag is pushed through the os with the finger and held in place with the finger in the vagina until it is filled with sterile water by means of a bulb or fountain syringe. The hand is then withdrawn and the tube clamped or tied. Some traction is now made on the tube until the bag is pulled through the os. A larger bag with a circumference at the base of 28 to 30 cm. is then introduced and used in the same way. This method generally takes considerably longer than the other, and it may be desirable to let the patient come partly or entirely out from under the influence of the drug during its use.

Recently a strong, powerful metal dilator, operated by a screw, invented by Bossi, has been considerably used in Europe and very rarely in America. Numerous reports of severe and serious tears have shown this instrument to be dangerous and not to be recommended.

After dilatation, or during dilatation if it lasts very long and if the condition of the patient allows, it may be well to let her come out of the ether in order that the child may descend into the pelvis, and if possible be expelled spontaneously. Generally it is to be extracted by forceps or by version and extraction as soon as dilatation is effected. Of course if the child is dead craniotomy should be done.

When the cervix is not yet effaced, either before or at the beginning of labor, the problem of management is more difficult. Cervical incisions are not sufficient.

and sufficient manual dilatation or metreurys's will generally require many hours.

Such long-continued manipulation is dangerous, both on account of the anesthetic and the risks of infection and shock.

If the patient be in a hospital and if the physician possess the necessary skill the vaginal cesarean section will probably procure the best results. It is much safer than an attempt to extract through a partially dilated cervix, the old accouchement forcé. The patient properly prepared is placed on the table and the cervix grasped anteriorly by vulsellum forceps, one each side of the middle, which are then substituted by traction sutures. A longitudinal incision is then made from a short distance behind the meatus urinaris to the external os through the vaginal mucous membrane. The bladder is then separated from the cervix by means of gauze sponges, the loose tissues between the bladder and uterus yielding easily. The cervix is then cut through on the medium line with scissors. As the incision extends upward the edges are caught by vulsellum forceps, on which traction is made to bring more and more of the anterior wall of the uterus within reach. This is split through, the vesico-uterine fold of the peritoneum being pushed up. In this way an opening may be made large enough to admit easily the closed fist through which the head may be extracted. If the child be at term it may be well to split the posterior wall of the cervix. An incision is made in the posterior vaginal wall, the rectum separated and the cervix incised in the same way as the operation was done on the anterior wall. Sometimes it may be necessary, in order to get more room for extraction, to make cross incisions in the vaginal wall. Unless the head is in the pelvis delivery is accomplished best by version and extraction. After the birth of the child it is not necessary to deliver the placenta at once. This might lead to considerable and unnecessary hemorrhage and probably require packing of the uterus. If there has been no detachment of the placenta and no hemorrhage from the placental site, the cord should be cut short and pushed back with any protruding membrane by a sponge and the repair of the incisions begun. The edges of the uterine wound are caught with forceps as before and pulled down until the upper angle of the wound is in plain view. Then with a well-curved needle and strong catgut the wound is closed with interrupted sutures knotted on the inside of the uterus. Before the lower part of the cervix is repaired the placenta must be expressed and any hemorrhage checked by hot uterine injections. The vaginal incisions are closed in the usual way.

If the operation just described is impossible we must choose between giving all of our attention to securing elimination and controlling dangerous symptoms or cautiously assisting labor while attending to the general condition. If the patient is not overwhelmed with the eclamptic poison, if the convulsions are few, the coma not profound and the heart in good condition, the first may be the best plan to pursue. Morphin hypodermically in one-sixth to one-fourth grain doses up to three-fourths grain, is the most reliable agent to control convulsions. Profuse sweating by packing or hot air should be secured. Two to four drops of croton oil placed on the tongue will secure free and prompt purgation.

Bleeding from the arm will rarely be required, but in desperate cases should be resorted to. The subcutaneous injection of one to two pints of normal salt solution will often have a favorable effect. Oxygen should always be used to relieve the overburdened heart.

In connection with these measures, when the symptoms are more urgent, we may induce labor or slowly dilate the cervix. As before stated, rapid dilatation and extraction in these cases is impossible, and any attempt in this direction is apt to lead to great disaster. The proper way to proceed is to anesthetize and prepare the patient, dilate the cervix with a branch or solid dilator to admit one finger, rupture the membranes and introduce a small Voorhees bag. Then ether should be withdrawn and the patient put back in bed. With careful control of symptoms and care for elimination as outlined above the labor should be allowed to progress until the bag is expelled. Then if necessary the anesthetic should be given again and another bag inserted, and again labor be allowed to proceed as before. Finally, after the cervix is well dilated, or after the effacement is complete and more active dilatation is safe, more active measures may be taken to deliver the child.

THE USE AND ABUSE OF HYPNOTICS.*

W. BLAIR STEWART, A.M., M.D.
ATLANTIC CITY, N. J.

"Take a trional powder when you retire and you will not be troubled with insomnia." This is a too common advice given to the laity and patients when either time or lack of interest prevents a thorough examination for the cause of the insomnia. Before falling into the rut of routine hypnotics, it is well to take more time to study every case of insomnia and ferret out the cause, remove it if possible, and little sleep-giving medicine will be needed. It should be remembered that insomnia is a condition or symptom dependent on some disturbing influence in or out of the body. Why give a hypnotic if acute indigestion is the cause; if high or moderate fever is present; if there is an earache, toothache or severe neuralgia; if a brass band is playing next door; if some unusual noise is disturbing? Do we always stop to consider and inquire into these and many other possibilities before we prescribe?

One gentleman who had undergone treatment at the hands of many admitted that no one had given his case a close study, but all jumped to the same conclusion, and had about exhausted the list of narcotic and hypnotic remedies. He was on the verge of a complete nervous breakdown. His constant symptoms were dizziness and a continued buzzing sound referable to the frontal region. Examination revealed errors in dietetics and an impacted auditory canal—the accumulated and hardened serous and waxy discharge impinged on a perforated and inflamed membrana tympani. Do I need ask why hypnotics failed here? Simple dietetic rules and proper treatment soon brought relief, but not at once, because Nature is a great creature of habit, and insomnia once fixed is sometimes very hard to eradicate. We may remove the cause of insomnia or neurasthenia in cases of long standing, but the effects will linger for days and even months before a return to normal is probable. Better nights will come by degrees until Nature reasserts herself. Unhappy is the man who, burdened with debts, business cares, unpleasant home relations and indigestion, retires to his bed night after night to toss and roll in a broken, dreamy and unsatisfactory few hours' sleep! Will we give him his sleeping potion, gradually increased, until he becomes a complete wreck and finally lands in an asylum or commits suicide?

---

* Read before the Atlantic County (N. J.) Medical Society, March 18, 1904.

How about the broker on the exchange? The man who works eighteen and twenty hours out of the twenty-four? The professional gambler? The man who is constantly using liquors to excess but not to intoxication? Shall we give these hypnotics? At an hour when sleep is most needful, should we give a narcotic or hypnotic to a crying child to induce sleep? Is it a case of earache, indigestion, too much or too little cover, fear, fever, night terrors, or some other condition? These are a few of the possible conditions that may be slighted and the hypnotic given as a matter of routine.

We should never overlook the fact that a close, warm and poorly ventilated room is often the cause of insomnia and disturbed sleep. It is a bad policy to sleep in a room with a burning light or gas jet, as a poor hypnotic effect is realized. The practice of inducing sleep by the inhalation of chloroform, ether and benzine can not be too strongly condemned. It is dangerous and injurious, and soon becomes a fixed habit. Hypnotic suggestion is often valuable. Gentle stroking massage of the forehead and neck will often induce sleep. Many persons will lie awake for hours, but if a cup of warm milk or bouillon is taken on retiring, Nature is soothed and sleep comes. Conversation, argument, games of chance, light reading and brain work should be avoided immediately preceding retiring, as these induce wakefulness. Many patients come with the tale of no sleep even for one hour, for one, two and three weeks at a time. While it is unnecessary, inadvisable and useless to question their veracity and to argue with them, we should accept their statement *cum grano salis,* and be governed accordingly. Such patients find considerable broken rest every twenty-four hours (there may be an occasional exception), and instead of prescribing strong hypnotics, we should seek for the possible causes, treat them and be absolutely positive in assuring results. This class of invalids should never be deceived, for the least-discovered deception will prevent the accomplishment of good. Some will occasionally need hypnotics, while others will benefit from a placebo. Mild massage, warm baths and warm-oil rubs at bedtime are often good sleep producers.

Many neurasthenics and overworked people drink a glass of beer or take a small drink of whiskey at bedtime to induce sleep. It works well in most cases, but as time passes the small drink has grown to be a glassful, and often one-quarter to one-half pint of whiskey. Sleep will not come without it. Such sleep is not restful, and the toxic effects of alcohol are produced next day—nervousness, irritability, headache, poor appetite and often delusions. We must be careful how we order alcohol as a hypnotic. It is a fine remedy in some cases, but a two-edged sword in others. It is so convenient as a remedy that some physicians fall into its use and very soon, to their discredit, its abuse. When a physician reaches a constant state of insomnia he is a candidate for a rest cure and change, and not a course of hypnotics—so with all business men. Two of my most prominent patients in Philadelphia, when under extreme stress of business cares, can not sleep at home, but come to Atlantic City in the evening and sleep in the soporific influence of the sea air as calmly as a healthy child, and arise next morning fresh and vigorous—not drug logged. One writer has aptly said: "Insomnia is the rich man's burden—sleep the poor man's blessing." The rich constantly live in the future—the poor for to-day—thus causing most cases of insomnia in the former.

They tell us that trional and sulfonal are harmless hypnotics, and can be given almost with impunity within prescribed dosage. I do not believe any such nonsense. Those of us who have had the opportunity to study cases where either remedy has been constantly used will frequently find an individual who is extremely nervous; whose power of endurance is low; whose heart action is nervous and often weak and irregular. There are headache, backaches, general depression, loss of vitality and often memory, poor appetite, constipation or diarrhea, dizzy spells, or in fact many present a condition the Germans call *schwach.* Many begin with slight nervous or exhaustive insomnia, and by a constant use of trional or sulfonal substitute a train of real toxic symptoms that are too often incorrectly diagnosed neurasthenia. These two hypnotics are among the most valuable, insofar as small after-effects are concerned, when given occasionally; but in these, as in all others, we should always anticipate secondary toxic effects, and never fall into the rut of prolonged administration—we must look for the cause of insomnia and treat it.

Chloral, bromids, hyoscyamus, opium, paraldehyd, morphin, heroin, donoin and hundreds of others have their special indications in selected cases—never for prolonged use, but often for prolonged abuse. When we prescribe a hypnotic, we must do it intelligently and with due consideration, after we have given sufficient thought to justify its use. Many patients tax our resources and we meet with failures, but there is probably no case that exists without a cause. If that cause can be found by diagnostic or other methods, it is necessary to remove it or have it removed if possible; if such can not be done, we will be burdened by a toxicized hypnotic sufferer until death comes to his rescue. Volumes could be written on this interesting line, but let us listen to the words of Longfellow when he writes:

SLEEP.

Lull me to sleep, ye winds, whose fitful sound
Seems from some faint Æolian harpstring caught;
Seal up the hundred wakeful eyes of thought
As Hermes with his lyre in sleep profound
The hundred wakeful eyes of Argus bound;
For I am weary, and am overwrought
With too much toil, with too much care distraught,
And with the iron crown of anguish crowned.
Lay thy soft hand upon my brow and cheek,
O peaceful sleep! until from pain released
I breathe again uninterrupted breath!
Ah, with what subtle meaning did the Greek
Call the lesser mystery at the feast
Whereof the greater mystery is death.

OUR SEROTHERAPEUTIC MEASURES.

H. T. RICKETTS, M.D.
CHICAGO.

The publication of an article of this general nature[1] seems justifiable. in order to extend familiarity with a phase of medical progress, which is nothing less than epochal in its achievements. It is also desirable that we appreciate the nature and degree of permanence of the results so far obtained in serum therapy, its present range of application and limitations, and the underlying principles of the successes and failures insofar as they are understood, in order that we may hold ourselves in a proper state of receptivity for results which the future is likely to provide.

---

[1] It seems unnecessary to give detailed literature here. The fundamental facts may be found in one of the following monographs: Dieudonné: Immunität, Schutzimpfung und Serumtherapie, Leipsic, Joh. Ambrosius Barth, 1903; Marx: Diagnostik, Serumtherapie und Prophylaxe, Berlin, Hirschwald, 1902; Deutsch und Feistmantel: Die Impfstoffe und Sera, Leipsic, Geo. Thieme, 1903.

The most distinctive features, medically and surgically, of the period in which we find ourselves, have developed from the knowledge of microbic etiology of the infectious diseases. Among the consequences of this knowledge, one of the most important is that the body, in the presence of an infection, has the power to produce specific substances, which antagonize the etiologic factor—toxin or bacterium. From this foundation our present serotherapeutic measures have been evolved.

Although the limits of this paper do not permit a detailed consideration of the developmental steps, yet it may contribute somewhat to consecutiveness to enumerate the following as the essential discoveries which have led to our present theories and practices: 1, The long-known efficacy of smallpox vaccination, which eventually led some investigators to think that this might be an example of a law capable of more general application; 2, the discovery, by Rayer and Devaine (1850), of "small filiform bodies" in the blood of sheep which had died of anthrax, which constituted an introduction to the domain of microbic etiology; 3, Pasteur's discoveries of the causes of fermentations, 1857-1861, and of the specific nature of the cause in a particular type of fermentation, i. e., microbic specificity; 4, Pasteur's investigations on the causes of epidemic silk-worm diseases; 5, the discovery of the microbic causes of many human and animal diseases by Pasteur, Koch and others; 6, Toussaint's partly successful attempts to vaccinate against anthrax by injecting anthrax blood which had been heated to 55 C. for ten minutes; this procedure killed the adult bacteria, but left the virulent spores unharmed, as a consequence of which many of the inoculated sheep died; 7, Pasteur's successful vaccine against anthrax, obtained by growing the bacillus under such conditions that it did not form spores; 8, the discovery of the bactericidal powers of the blood and serum by Fodor, Nuttal, Buchner, Nissen and Behring; 9, the discoveries of Behring and of Bouchard, that if an animal receives repeated injections of a microbe, the serum gains in bactericidal powers for the microbe used and the new power is specific; 10, announcement of the finding of the toxins of diphtheria (Roux) and tetanus (Brieger and Fraenkel); 11, the discovery that by immunizing an animal with a toxin, an antitoxin is formed; tetanus and diphtheria (Behring and Kitasato), ricin and abrin, vegetable poisons (Ehrlich); 12, the gradually evolved fact that if the serum of an immunized animal is injected into another, the latter may be protected from an otherwise fatal dose of the infecting agent, in which the Pfeiffer school took a prominent part; 13, the discovery that the bactericidal power of a serum depends on the combined action of two substances in the serum (Bordet); 14, the theory of phagocytosis (Metchnikoff); 15, the conception of the chemical nature of the reactions occurring in immunity, and the "side-chain" theory (Ehrlich).

From the above it is seen that after the principle of microbic specificity of infectious diseases was established, the next great stride was in the direction of protective inoculations. For this purpose the bacteria alone, either in a virulent or an attenuated form, were used; later, certain bacterial products were utilized for the same purpose. This method constitutes an active (Ehrlich) or isopathic (Behring) immunization of the animal. After the discovery of antitoxic and antibacterial serums it was found that they, too, could be used as protective agents (passive immunization according to Ehrlich). Certain of these procedures have also been found to have a curative value, the administration of diphtheria antitoxin holding the highest place in this regard. One may then classify the methods of rendering the body immune to infections and certain toxic diseases as follows:

I. PROPHYLACTIC INJECTIONS.

A. Active immunization.
  1. Inoculation with virulent infecting agents:
    A. Inoculation with small amounts of a virulent organism, i. e., of a non-fatal dose.
    B. Inoculation with a virulent organism into a tissue which is resistant to the infecting agent; the success of vaccination against smallpox by using the virus obtained directly from the diseased, which was practiced in earlier times, was probably due to the fact that the virus found unfavorable conditions for the development of virulence in the skin; in some instances vaccination is more successfully accomplished by direct inoculation of virulent organisms into the blood stream (Kitt's method of vaccination against symptomatic anthrax).
    C. The simultaneous injection of an immune serum with the infecting agent, the serum temporarily increasing the resistance of the animal; swine erysipelas, swine plague, rinderpest (mixed active and passive immunization).
  2. Injection of attenuated infecting agents; attenuation by air and light (chicken-cholera, Pasteur); by cultivation at high temperatures (anthrax, Pasteur); by chemical agents (anthrax, Roux; diphtheria and tetanus toxins, Behring, Roux); by desiccation (rabies, Pasteur); by passage through other animals (swine erysipelas, Pasteur); this last observation was a most instructive one; passing the bacillus through the rabbit several times increased the virulence of the organism for the rabbit, but decreased it for swine, while passing it through the dove increased the virulence for the swine; the former product was used as vaccine I, the latter as vaccine II.
  3. Injection of killed organisms (anthrax, Toussaint, 1880; swine plague, Salmon and Smith, 1886). This method is of the utmost importance in human diseases, as it is the safest means of vaccinating against cholera, typhoid and plague. In the Pasteur treatment of hydrophobia the first injection of the dried rabic cord probably contains the killed virus.
  4. Injection of bacterial products:
    A. Bacterial cell plasm (Buchner's plasmine, obtained by submitting the organisms to high pressure; and Koch's tuberculin TR).
    B. Soluble bacterial products (the bacterial proteins, as Koch's old tuberculin, mallein, the soluble toxins, and the products of bacterial autolysis).

B. Passive immunization: The prophylactic injection of antibacterial and antitoxic sera.

II. CURATIVE INJECTIONS.

A. Active immunization.
  1. Injection of killed micro-organisms in small doses with the intention of hastening antibody formation (Fraenkel in typhoid fever); value not yet demonstrated.
  2. Injection of bacterial products; e. g., the attempt to cure tuberculosis by the injection of tuberculin (Koch).

B. Passive immunization.
  1. With antitoxic sera; in diphtheria, tetanus, snake bites, plague, tuberculosis (?), typhoid fever (?), streptococcus infections (?), etc.

2. With antibacterial sera; in typhoid, cholera, plague, dysentery, streptococcus, staphylococcus and pneumococcus infections; of these the antiplague serum of Roux and Yersin seems to have the most value.

This seemingly intricate classification, which is taken in part from that of Deutsch and Feistmantel,[2] may be simplified for the purpose of this work as follows:

I. Protective injections.
  1. Antibacterial vaccination.
  2. Prophylactic injection of antitoxic sera.
  3. Prophylactic injection of antibacterial sera.
II. Curative injections.
  4. Antitoxic sera.
  5. Antibacterial sera.

It is important to bear in mind that in the struggle of the body against infections there are two principles of action—the antitoxic, directed against bacterial toxins, and the antibacterial, directed against the bacteria themselves. The two are absolutely distinct. A serum which is strongly bactericidal may have no power of neutralizing the toxin of the microbe, and vice versa, an antitoxic serum may not be able to kill the bacterium. Each of the five procedures enumerated above, then, is efficient, either because a greater bactericidal power or a greater antitoxic power is introduced into or induced in the body. In 1, the body reacts in such a way that its power to kill the micro-organism is increased (active immunization), while in 2, 3, 4 and 5, "ready-made" immunizing substances are introduced from without (passive immunization).

It is readily appreciated that after the possibility to vaccinate against diseases of known bacterial origin was known, the nature of the reaction in the body became the subject of investigation. The attempts to answer the question, what had happened in the body to change its resistance, gave rise to the various theories of immunity which have been current at various times. The exhaustion theory of Pasteur, at one time supported by Koch and by Klebs, the noxious retention theory of Chauveau and the allied theory of Baumgarten, have had to give way before the accumulated facts, which showed that new substances appeared in the blood as the result of an unusual and specific cell metabolism, having the microbic poisons as the stimulus. The phagocytic theory of Metchnikoff, as first formulated, at a time when toxic and antitoxic action was not appreciated, referred immunity to diseases and recovery from them to the ability of various cells of the body, especially the leucocytes, to ingest and kill the bacteria. When, however, it was discovered that antitoxic and bactericidal substances were formed and could be demonstrated in the serum of the blood, it became necessary to ascribe new functions to the phagocytes if they were to retain the exclusive dignity of protecting the body against all manner of infectious diseases. To accomplish this it was necessary to assume that the phagocytes are resorptive cells in a broad sense; that they take up, not only formed elements, but also unformed, and that antitoxin and the antibacterial bodies are the result of phagocytic metabolism.

The most recent theory, and one which has gained wide recognition, is the side-chain theory of Ehrlich, a brief consideration of which seems advisable here, because of its wide application and its tendency to put the reactions of immunity on a chemical basis. It is supposed that nutritious molecules, as well as toxic, obtain access to the cell by uniting chemically with certain atom-groups of the cytoplasm. These atom-groups are a part of the more complex chemical structure of the cell; hence an outside substance which enters into combination with the cell in this manner is able to influence the whole cell in its chemistry and physiology. From this relationship it is understood why the atom-groups mentioned are called side chains in the sense of organic chemistry. Furthermore, as the side chains are the agencies through which food particles and toxins are received into the cell, they are also called receptors. Toxin then forms a chemical union with the cell through the medium of the receptor; hence the receptor can play an injurious rôle for the cell, in the case of toxin, while it also plays a useful rôle in the case of food substances. When a toxin molecule is once united with a cell receptor it is, naturally, not free to injure other cells. Now if, through some agency, a cell receptor should be separated from the cell and thrown off into the circulation, it would still have the power of uniting with a toxin molecule, so that here also the latter would not be free to injure cells. Now there appears to be a general law, first enunciated by Weigert, that when a tissue is injured its cells reproduce not only to the extent of making good the defect, but to an excess; scar formation is cited as an example of this process. Transferring this conception to cell metabolism, when a cell is injured by having a side chain (receptor) neutralized or destroyed, it reproduces not one but many side chains to take the place of the one bound to the toxin molecule. In antitoxin formation the overproduction of receptors takes place to such a degree that they are thrown off from the cell into the circulation; these cast-off receptors constitute our antitoxin. Certain phenomena in the union of toxin and antitoxin make it convenient to assume that the two unite through the agency of certain atom complexes which each possess; these are called the binding or haptophore groups of the molecules. It is, furthermore, considered and proved, that the ability of the toxin molecule to produce injury rests in another group which is called the toxophore. The evidence of this lies chiefly in the fact that an old toxin which has lost its toxic powers is still able to produce a strong antitoxin by immunization; accordingly, it must still have a binding group, while the loss of toxicity is ascribed to the degeneration or disappearance of the toxic group—the toxophore. This degenerated toxin is called toxoid. The toxin molecule then contains a haptophore and a toxophore group, while for antitoxin it is necessary to assume the existence of only a haptophore group. The neutralization of toxin by antitoxin may then be considered as relatively simple, and that it takes place according to the general laws of chemical reactions is shown by an abundance of experimental evidence. A new innocuous compound is formed, no digestive or ferment-like action coming into play. This was proved by Calmette for venom, and by Wasserman for pyocyaneus antitoxin.

On the other hand, the destruction of bacteria by a bactericidal serum seems to be far more complicated. Bordet's discovery was mentioned at the outset, that the power of a serum to kill bacteria depends on the presence of two substances, neither of which alone is active. One of these bodies, the amboceptor (Ehrlich nomenclature) is greatly increased by the immunization of an animal, or during the natural recovery from microbic disease. Like the antitoxin it has a normal residence in the body cells, where it exists as a cell receptor, and it is reproduced to excess in the same manner. It differs from the antitoxin receptor, however, in having two haptophore groups instead of one; through one it is able to form a union with the bacterial cell, through the other with the complement. It is fairly resistant to the destructive effects of light and heat and air; and as intimated, acts as an intermediary body between the bacterium and the complement. Complement, the second body, exists normally in the body fluids, is practically not increased by immunization, is easily destroyed by heat, light and air, and after being united to the cell through the medium of the amboceptor destroys it by a ferment-like (?) action. Inasmuch as it unites with the amboceptor, a haptophore group is ascribed to it; since, also, observations show that it has a toxophore or zymotoxic group, its structure is not unlike that of the toxin molecule. The degeneration of the zymotoxic group gives rise to complementoid.

---

[2] Die Impfstoffe und Sera, Leipsic, Geo. Thieme, 1903.

If, in the above, the fundamental conceptions of Metchnikoff and of Ehrlich have been stated clearly, it can be seen that there is no essential conflict between the two. Metchnikoff makes the phagocytic cells of the body the producers of the immunizing substances to the exclusion of other cells, while the Ehrlich theory is broader in this respect. On the other hand, the latter theory does not necessarily deny to the phagocytes an important function in recovery from infections.

PRACTICAL RESULTS.

A summary of the practical results of serotherapeutic measures may now be given, taking up separately the five procedures classified above.

1. *Antimicrobic Vaccination.*—This continues to be applied along the lines laid down by Pasteur. In all probability vaccination against smallpox, and the Pasteur treatment of hydrophobia, the success of which are sufficiently well known, fall into this group. In vaccinating against anthrax and chicken cholera Pasteur used attenuated and virulent organisms. Since that time killed organisms and certain bacterial products or extracts have been used for the same purpose in various diseases. In accordance with the procedure one would expect the development of antibacterial substances in the blood, in the form of specific amboceptors, while an antitoxin is not necessarily formed. In the cases of typhoid, cholera, plague and dysentery bactericidal amboceptors are formed, and are capable of ready demonstration *in vitro,* their activity depending, however, on the presence of complement as indicated above. Since such bodies are demonstrable *in vitro,* it is logical to assume that the protection afforded by vaccination is due to their presence in the vaccinated body. Concerning another class of organisms where vaccination is accomplished less readily (streptococcus, staphylococcus, pneumococcus, tubercle bacillus and others), the demonstration of bactericidal antibodies *in vitro* is not so satisfactory, although the antiserum in some cases is able to protect another animal from an otherwise fatal infection.[3] Accordingly, against this class of organisms the mode of protection in the body is more obscure than in the first group; and as immunization with them is not accomplished in one or two injections they are not practically employed in protective inoculations.

So far as man is concerned application of this procedure is made against cholera, typhoid and plague and bacillary dysentery (Kruse). Our largest statistics on anticholera vaccination come from the Haffkine method (1892), practiced especially in India, in which two injections are made; first, a culture of low virulence followed, some days later, by one of high virulence. Kolle claims that a single injection of the killed vibrio has the same value as that of the living. Haffkine also introduced antiplague vaccination into India in 1896, using cultures which had been killed by heat, for the inoculations. Lustig and Galeotti, on the other hand, prepared a dried vaccine by first extracting the bacilli with potassium hydrate solution, then precipitating with acetic acid. The washed and dried precipitate constitutes the vaccine and is also used in the immunization of animals to obtain an antitoxic plague serum. Antityphoid vaccination received its first experimental support from Pfeiffer and Kolle in 1896, but we are indebted to Wright of the British army for the most extensive statistics concerning its value as practiced among the troops of South Africa and India.

It seems unnecessary to enter here into a discussion of the statistics which have been compiled in reference to vaccination against these three diseases. The essentials are to be found in any one of the monographs mentioned at the outset, and Wright's reports have appeared in the British journals at intervals during the past few years. In general, it may be said that the reports show that the percentage of cases which develop among the inoculated is distinctly below that of the uninoculated, and, moreover, that when the disease does occur in the inoculated it appears to be less virulent than in the uninoculated. The statistics indicate such a degree of success that we may consider the method one of established value, and one to be practiced under the proper circumstances. Plague and cholera hardly concern our communities at present. In regard to typhoid, however, we still have in mind the epidemics which occurred in Ithaca, N. Y., and Butler, Pa., where the conditions seem to have been such that the vaccination of all uninfected within the danger limits would have been a warrantable procedure. We also remember, not many months ago, an outbreak of typhoid fever in a circumscribed district in Chicago, where antityphoid vaccination would have found a suitable field. So far as known there can be but one source of danger in the procedure. Experiments with the serum of man and animals show that, after the inoculation several days must elapse before the immunizing substances are increased, and what is of greater importance, the natural resistance of the animal may be in the meanwhile slightly decreased. This would appear to create a danger period for the inoculated in the presence of an epidemic, but certainly not a danger of magnitude, as the period of decreased resistance has a duration seemingly of but a few days. It seems, moreover, that this danger can be eliminated by the simultaneous injection of the specific immune serum. On the other hand, the increased resistance which follows vaccination is well sustained, being clearly evident in both cholera and typhoid after thirteen or fourteen months. Opportunity has not yet been afforded to judge of the value of antidysentery vaccination.

Protective inoculation (more strictly, immunization) against tuberculosis has been confined entirely to animals. Setting aside the dubious results obtained by immunization with tuberculin, interest at present centers on the method of immunizing with avirulent or attenuated cultures of the bacillus. Of importance in this connection is the position taken by Koch that the human and bovine bacilli are not the same organisms, at least in their pathogenic powers; that the human bacillus is less pathogenic for cattle than for man, and the bovine bacillus less pathogenic for man than for cattle. Hence he has proposed the immunization of cattle with the human bacillus, and he and his followers claim a good degree of success. Trudeau and de Schweinitz in this country, von Behring in Germany, and Maragliano in Italy, have for a number of years carried on similar work, likewise with some success. As bacilli of low virulence one may use attenuated human or bovine bacilli, the avian or fish bacillus, or as Friedman has recently done, an organism cultivated from the turtle. Friedman claims to have successfully immunized guinea-pigs, the most susceptible of all animals, against infection with the most virulent tubercle bacillus. While this work is of the utmost interest, the methods are naturally not applicable in human therapy at present.

---

[3] Denys found that an antistreptococcus serum was made streptococcidal by the addition of fresh leucocytes; Tavel confirmed this and in addition claimed that the fresh serum was streptococcidal for a brief period (one hour); the statement then that antistreptococcus serum is not bactericidal must be accepted with some reservation

2. *Prophylactic Injection of Antitoxic Serums.*—The value of diphtheria antitoxin as a prophylactic is so well recognized that it need not be discussed now. Tetanus antitoxin, on the other hand, is much neglected in this its most promising aspect. However disappointing it has been as a curative agent, there is evidence to show that its value as a prophylactic is almost equal to that of diphtheria antitoxin. This value is apparently better appreciated by veterinarians than by medical men. A celebrated example of its protective value concerns an epidemic of tetanus in an obstetric clinic in Prague which was completely suppressed by injecting all patients with the antitoxin after all other precautions had failed. Evidence of equal value is also accumulating in this country by giving the antitoxin in cases of Fourth of July wounds before tetanus has had time to develop.

3. *Prophylactic Injection of Antibacterial Serums.*—Pfeiffer and his pupils have made us familiar with the fact that animals can be protected against cholera and typhoid by first administering the antisera of these organisms. Similar conditions prevail with the majority of our pathogenic microbes, as shown by facts which have been worked out by many observers. The injection of the serum is best made twenty-four hours in advance of the infection. This immunity is unfortunately one of short duration, as after two or three weeks the protective substances are eliminated. To sustain the immunity by frequent injections would be arduous, and might, moreover, be injurious, since investigations have shown that it is possible to establish an immunity to an immune serum; this would be equivalent to annihilating the individual's natural resistance to the disease. For these reasons the method has had a very limited application. Inasmuch as the immunity conferred by this method is immediate, though transient, while by the vaccination method some days are required for the development of protective substances, it has been proposed to combine the two. If this can be carried out successfully, it will be possible to obviate every disadvantage in connection with vaccination against typhoid, cholera and plague. Besredka has proposed saturating the killed or living bacteria with their specific amboceptors and using this preparation as a vaccine. His animal experiments showed that immunity was conferred immediately and had a duration of at least nine months.

4. *Curative Injection of Antitoxic Serums.*—The efficacy of diphtheria antitoxin is so well known that no comment is called for. The early administration of sufficiently large amounts in mild as well as malignant cases, repetition of the injection if prompt subsidence does not occur, and its use in doubtful cases are the points to be kept in mind.

One might dismiss tetanus antitoxin, as a curative agent, with almost equal brevity, by saying that little is to be hoped from it in its present form and methods of application. I have already dwelt on its great value as a prophylactic. The work of Marie, and more recently that of Meyer and Ransom, which apparently show that the toxin reaches the central nervous system through the axis cylinders of the peripheral nerves, point to the intraneural injection of the antitoxin as a procedure of possible value. In spite of what has been said, the occasional reports of cases supposed to have been cured by the antitoxin justify its continued application, in particular the subdural injections.

Calmette's antivenin is efficient in animal experiments, and no doubt it would be equally so in man if used early enough.

Maragliano claims high value for his tuberculosis antitoxin as a curative measure, but its use has apparently not extended.

Nothing can be said at present concerning the efficacy of Marmorek's new tuberculosis antitoxin; the results so far are certainly not encouraging.

Distinct curative power is ascribed to the pest antitoxic serum of Lustig as used in India. The typhoid antitoxic serum of Chantemesse has been so little used that its value is not definitely established.

5. *Curative Injection of Antibacterial Sera.*—This concerns the class of microbes which, it is currently supposed, do not form soluble toxins. In this group one must distinguish between the sera which are bactericidal (*in vitro*), and those which are not. As already indicated, among the former are the typhoid, cholera, plague and dysentery sera; among the latter the sera of the streptococcus, staphylococcus and pneumococcus. In spite of this difference both types of serum are actually antibacterial when injected into an animal in advance of the infection, the power of the former being in excess of the latter. If, on the other hand, the bacteria are injected first, the efficiency of the serum decreases so rapidly that only in exceptional instances will any quantity save the animal after the lapse of twenty-four hours. That is to say, such sera as now constituted have little power over established infections, and since in man we are called on to treat established infections, they offer little hope as curative procedures. Cholera antiserum has no prospects, according to Pfeiffer, inasmuch as the situation of the vibrios in the intestinal canal makes them inaccessible to a possible action of the serum. A probable exception lies in the antipest serum of Roux and Yersin, of which 0.5 c.c. will save a mouse sixteen to twenty hours after the infection. In Yersin's hands the mortality in man was reduced from 80 per cent. to 49 per cent.; in the hands of Calmette and Salimbini in the Oporto epidemic, from 63.72 per cent. to 14.78 per cent. Likewise Kruse's antidysentery serum may prove of distinct value.

Antistreptococcus sera are classed as monovalent and polyvalent, depending on whether one or several races were used in the immunization. The sera of Marmorek and Aronson are monovalent; those of Tavel, Moser and Menzer are polyvalent. The object in using several different cultures of streptococci in the immunization is that the resulting serum may be active against a larger variety of streptococcus infections, it being supposed that there are biologically several types of streptococci. As stated, such sera are not conspicuously bactericidal *in vitro;* hence it is not known on what their action depends. They may have antitoxic powers in the animal's body, may unite with a tissue substance to constitute a bactericidal substance, or may in some way stimulate phagocytosis. Marmorek claims antitoxic properties for his serum.

They are used against various streptococcus infections, particularly streptococcus septicemia and erysipelas; furthermore, against scarlet fever (Moser-Escherich, Aronson-Baginsky), and acute rheumatism (Menzer) on the as yet unproved assumptions that these diseases are caused by streptococci. Moser and Escherich, and to a less degree Baginsky, in scarlet fever, Menzer in rheumatism, and Tavel and Marmorek in various streptococcus infections, claim benefits from the use of their serums; but to the disinterested their results seem at present indecisive.

What has been said of antistreptococcus serums as curative measures can also be said of antipneumococcus and antistaphylococcus serums.

There is occasion for protest here in that a most essential control is so seldom made. In animal experiments we demand that the effect of an antiserum be controlled by the effect of a normal serum from the same source. Now, if an antiserum had such decisive value as diphtheria antitoxin the control could well be omitted in man. Inasmuch, however, as the value of these serums is in question, the controls should be made, and could be made without jeopardizing the welfare of the patients. As an illustration, one may quote the work of Römer, who claims curative power for antipneumococcus serum in the treatment of serpent ulcer of the cornea. The treatment consists of the local infiltration of the serum by means of a syringe. It is quite possible that the injection of a like amount of normal serum would have been followed by equally good results. This consideration acquires more importance when we recall that it was long ago demonstrated that various indifferent fluids when injected into the abdominal cavity of an animal increase the resistance of the animal to a subsequent abdominal infection.

GENERAL CONSIDERATIONS.

The Time Element and the Question of Affinity.—Diphtheria antitoxin when injected into an animal will protect him against an attack of diphtheria; it will likewise cure the established disease when given in time, and when mixed with the toxin in the test-glass neutralizes it in chemical proportions. Tetanus antitoxin is also able in the test-glass to neutralize the corresponding toxin in exact chemical proportions, and when injected into an animal will protect against a subsequent infection with the toxin or the bacillus. So far it is parallel with diphtheria antitoxin in its efficacy. When, however, the disease, tetanus, has declared itself clinically, its value as a curative measure falls far below that of diphtheria antitoxin.

It is also well known that both in diphtheria and tetanus, the earlier the antitoxin is administered the more certainly can cure be accomplished and the less antitoxin is required to work the cure; conversely, the longer the antitoxin is delayed the more remote are chances for cure, and the more antitoxin is required if the cure is accomplished. If a neutral mixture of tetanus toxin and antitoxin is injected into an animal no tetanus results. Dönitz found that if the toxin were injected first and the antitoxin four minutes later, a slight excess of antitoxin was required for neutralization; if he waited eight minutes six times as much antitoxin, after sixteen minutes twelve times as much, after one hour twenty-four times the simple neutralizing dose was required. A few hours later no amount of antitoxin could save the animal.

In explanation of these facts the following points are to be considered: In the test-glass are toxin and antitoxin alone, two substances capable of entering into a chemical reaction; there is no third substance which has an affinity for one or the other. If two times as much toxin is added two times as much antitoxin will neutralize it. When, however, the toxin gets into the body, it is in the presence of a third factor—the tissue cells—for which it has an affinity equal to if not greater than that it has for the antitoxin. Tetanus toxin accordingly will form a chemical union with nervous protoplasm when the two come into contact. Even after four minutes a certain amount of toxin was bound in Dönitz' experiments. When the antitoxin was injected a certain amount of it was required to neutralize the toxin still unbound by tissue cells, while all above the simple neutralizing dose was required to tear away the toxin already bound. Accordingly, after one hour, when twenty-four times the simple neutralizing dose was required for this, the figure 24 represents the affinity of the bound toxin for the nervous cells. This is interpreted in chemical terms as a mass action on the part of the antitoxin, i. e., it represents the amount of antitoxin necessary to dissociate the toxin—nerve-cell compound. As stated, a time is rapidly reached when no amount of antitoxin will save the animal. At this time the process passes beyond that of simple chemical union of toxin and tissue. Further chemical action, of a biologic nature, sets in, as a result of which the toxin probably becomes an integral part of the cytoplasm and proceeds to its injurious action, whatever the nature of this action may be.

In view of these facts, the efficacy of early as compared with late administration of antitoxin finds a logical explanation. Now, early and late are relative terms; what is early for diphtheria is late for tetanus. In either case the disease begins at the time of the infection, and, on this basis, the second day of diphtheria may correspond to the tenth or fourteenth day of tetanus. Hence the success of the serum therapy depends on the administration of the serum as soon as possible after infection.

In diphtheria there is no means of suspecting infection until the disease has declared itself; in tetanus, on the other hand, although the diagnosis can not be established until clinical symptoms have appeared, the nature of the wound is often sufficient to arouse suspicion as to tetanus infection. In all such cases the failure to give the antitoxin prophylactically amounts to a gross neglect of duty.

Concerning the Low Value of Antibacterial Sera.—Sufficient has already been said about the time element in the administration of antibacterial serums. As the exact reasons for the low curative value of these sera are still problematic, it is hardly proper in a general paper to more than mention briefly several possible factors.

1. The bacteria may be so situated in the body that they would be inaccessible to an immune serum. As stated Pfeiffer has given up hope of a successful treatment of cholera with a bactericidal serum on this basis.

2. The body cells may contain receptors, which are

able to unite either with the amboceptors or the complement, or both, and this affinity may be a greater one than that existing between the bacterium and amboceptor. This would effect a deviation of the amboceptors from the bacteria. That this is possible is shown by the fact that on immunizing an animal with an immune serum, anti-amboceptors may be formed; this could not happen unless it were possible for the amboceptors to unite with tissue cells. Also as anticomplement formation is readily induced, it is evident that complement may be bound by the tissue cells. Von Dungern[4] has demonstrated experimentally this binding of complement.

3. Since in an antibacterial serum, as one would purchase it on the market, all complement would long ago have disappeared, the amboceptors would have to depend for their activation on such complement as might be present in the patient's body. This might be too small in amount or not of the right sort. From this it is readily seen that the search for a universal or for various artificial complements or even for proper serum complements in abundance, is a problem of the utmost importance for the efficacy of these serums.

4. It is not yet assured that a powerful bactericidal serum would not, in destroying the bacteria, liberate a detrimental amount of intracellular toxin. A celebrated experiment of Pfeiffer's gives ground for this fear; a certain time after infecting a guinea-pig peritoneally with cholera, an amount of immune serum was given which killed all the bacteria, yet the animal died of intoxication.

5. Although it has been found possible to cure animals of typhoid and other infections when the proper time relationship is observed, even with small amounts of bactericidal serums, when these amounts are reckoned for man they reach as high as 600 or 700 c.c. This factor alone would make their extensive use impracticable.

Reference has been made to antibacterial serums which are not bactericidal *in vitro*. That such serums do contain protective antibodies of some nature seems clearly shown by the work of Wasserman on the pneumococcus, Peterson, Pröscher and others on the staphylocococus, Denys, van der Velde, Marmorek, Tavel, Moser and Menzer on the streptococcus. The opinion that such serums are protective because they stimulate phagocytosis, is somewhat prevalent (the Metchnikoff school attributes the curative action of all antibacterial serums to this process); and in view of the high leucocytosis present in streptococcus, staphylococcus and pneumococcus infections, and the fact that the serum of convalescents show no bactericidal power for their respective microbes, it seems impossible to divorce the leucocytes from a most active part in the recovery from these infections.

The Immunization of Bacteria.—If animal cells can be immunized against bacteria and their products, why can not bacteria be immunized against animal cells and their products? In other words, during the course of a disease, is it not possible for the protective substances of the body, by uniting chemically with the bacteria, to stimulate them to the production of anti-amboceptors or anticomplement, or both? This question has been discussed by Welch and others. These new-formed antibodies of bacterial origin would then combine with the protective substances of the body leaving the bacteria unantagonized. There is not yet sufficient evidence to show that this theory has practical importance, but that the bacteria are capable of reacting in this manner is shown by the recent works of Walker, Müller, Wechsberg and Eisenberg. There is, furthermore, in this connection, the long-known fact that a typhoid culture fresh from a patient is agglutinated less readily than one which has been on artificial culture media for some time. It would seem from this that the bacillus while in the body acquired anti-agglutination powers from being in contact with the agglutinating substances of the body fluids.

Artificial Complement and Amboceptor.—Inasmuch as complement is absolutely necessary for the action of a bactericidal serum, and since, moreover, its lability is extreme, the discovery of readily accessible artificial complements would be a step of evident value. Although such a substance has not been discovered for the amboceptor of a bactericidal serum, Kyes found that lecithin, a substance of known composition, would activate the hemolytic amboceptors of snake venom.

In this connection an observation by Landsteiner and Jagic[5] is of the highest interest. A colloidal solution of silicic acid has precipitating powers and will agglutinate red blood cells, but causes no solution of the corpuscles. If, however, a very small amount of lecithin is added to the agglutinated red cells, the latter are dissolved. Hence the silicic acid is the analogue of amboceptor, lecithin of complement in this reaction. Since also unheated serum would activate the hemolytic power of the silicic acid the analogy to the amboceptor and complement action of an immune serum is the more striking.

In the cytolytic process by a specific serum, we have, on the one hand, the body to be acted on (bacterium or tissue cell), and on the other hand, the acting substances, amboceptor and complement; all three are chemically unknown substances. In the condition which Kyes dealt with, one of the acting substances became a known quantity, the other active body and the body acted on being chemically unknown. In the experiments of Landsteiner and Jagic, both active substances were known bodies, the substance acted on remaining still unknown. I have recently had occasion to study a reaction in which the substance acted on is known, while the two active bodies are unknown. Nervous tissue contains two substances, by the combined action of which methylene blue can be changed into the colorless dye. One of the substances in the nervous tissue can be extracted by salt solution; the sediment (washed) is then unable to reduce the dye, but the power can be re-established by the addition to the sediment of a trace of serum, itself non-reducing. When methylene blue becomes the leuco-compound its composition is changed by the taking up of two hydrogen atoms; if this reaction were analogous to that of a cytolytic serum, it would suggest that cytolysis may be accomplished by a reduction process.

These observations encourage one to believe that a new point of departure has been established, which may lead to important results as to the chemistry of immunity.

The Influence of Inorganic Salts.—A number of years ago Buchner made observations tending to show that inorganic salts were important factors in the activity of a bactericidal serum. No theoretical or practical results of importance issued directly from his work, however.

---

[4] Beiträge zur Immunitätslehre; Münch. med. Woch., 1900, No. 20.

[5] Weiner klin. Woch., Jan. 21, 1904.

Professor Hektoen has taken up certain phases of this work recently, and finds that various salts, even in minute quantities, are able to inhibit the action of the complement of hemolytic and bactericidal serums. Hence it is not impossible that our susceptibility and resistance to various infections may be subject to important modifications because of the nature and concentration of the salts in the blood at a given time.

In conclusion, it is evident that very important laws have been discovered, in accordance with which certain immunity reactions occur. Certain of our serotherapeutic measures, in particular vaccination and the antitoxin treatment of diseases, justify the belief that the laws as enunciated are correct. However, the degree of failure which has accompanied the attempt to cure typhoid, cholera and other diseases with antibacterial serums, in themselves specific and often powerful, shows that to these laws are attached certain corollaries, the mastery of which must be accomplished before further progress is made in this direction. It is the opinion of many that an entirely new way must be opened up, but as to the course indicated there is no clear conception. Wright is of the opinion that our physicians must turn vaccinators, ready to give all who may wish a protective inoculation against typhoid, plague, streptococcus or pneumococcus infections. Although there may be possibilities in this procedure, man on the whole is too much of a procrastinator to seek for vaccination against a carbuncle which is not imminently threatening him, or an attack of typhoid fever in the absence of an epidemic. That there are conditions where such a procedure is distinctly called for has been indicated above.

What seems clear now is that antitoxin treatment for all our infectious diseases is above all else to be sought for. So far, however, all attempts to obtain from such bacteria as the typhoid bacillus, toxins, immunization with which will yield an antitoxic serum of value in treating the established infection, have failed. It remains to be seen whether the typhoid toxin which Macfadyen obtains by grinding the bacillus at the temperature of liquid air, will permit of the production of an antitoxin capable of influencing the disease as it occurs in man. If success is encountered in typhoid there is reason to hope that the method will find equal application in certain other diseases.

THE APOSTOLI TREATMENT.

THE FINAL RESULTS OF ITS USE IN SOME CASES OF FIBROID TUMOR OF THE UTERUS.*

G. BETTON MASSEY, M.D.
PHILADELPHIA.

It is now somewhat more than sixteen years since I began the electric treatment of fibroid tumors of the uterus after the method of the late Georges Apostoli of Paris, and having occasion recently to revise the subject for a work now in preparation, I have been strongly impressed with the desirability of giving to the profession a brief review of the practical results that have attended this work in this long series of years. The value of the Apostoli method was hotly contested in medical literature some years ago. The time has now come when a dispassionate conclusion as to its real value is in order.

It may be recalled also by some of you that this society appointed a commission to investigate this question during this controversy. I think the date of this commission's appointment was in 1889 or 1890. I am not aware that a report was ever made by it, and suggest that it is by no means too late for the work to be undertaken and a report prepared that would be of great service to science. The lapse of fourteen or fifteen years between the appointment and report of this commission would, indeed, be an advantage rather than a disadvantage, for the question at issue takes a considerable time for its determination when we remember that the treatment itself requires from six months to three years in a given case, and that an important part of the investigation relates to the practical results, as shown in the well-being of the patient in after years.

Should the commission decide to investigate the subject, it will find the majority of these patients living, and their present condition can be easily compared with the records of their original status as noted by competent physicians.

During the sixteen years mentioned I have had under more or less thorough treatment 110 cases of fibroids, which have been carefully tabulated in the exact order in which they were first seen. I have made efforts recently to ascertain the present condition of as many of these patients as could be found by letters, circulars and personal inquiries, with the following result:

Cases in which the results are unknown...........		9
Cases resulting in anatomic and symptomatic cure.... (Including 18 that disappeared by absorption, 3 extruded through cervix in whole or part, and 1 destroyed piecemeal by electrolysis.)	22	
Cases resulting in symptomatic cure only............ (Including 12 with great reduction in size, 26 with slight reduction in size, and 15 permanently relieved of symptoms without change in size.)	53	
Total cases resulting in practical success.........		75
Cases resulting in partial or complete failure.....		26
Total cases treated..............................		110

Excluding the 9 cases in which the results are unknown, largely transient patients at a public clinic, long since discontinued, it will be seen that the figures given show 75 actual or practical cures and 26 failures in 101 cases. In other words, three-quarters of the cases were successes and one-quarter failures.

The word "failure" should be further defined in connection with this work. With the exception of the result in one case, it means that the patient is left in a condition exactly the same as before treatment, and in a position to accept operative removal if necessary or desirable. The exception was an instance of death from septicemia in the year 1888, due to the failure to recognize the existence of a cystic condition, an error of diagnosis which was shared with one of the most eminent of living gynecologists. How many of the remaining 25 failures were subsequently operated on is uncertain, except in the cases of seven patients, in three of which the operation was undertaken at my suggestion.

Turning from the failures to the successes, it will be noted that the result was satisfactory in three-quarters of the cases treated with known results. This is an important fact. The majority of these patients were contemplating operative removal when they sought advice, with all that it implied in danger to life and certainty of unsexing results. These women are to-day happy wives—some even disconsolate widows—for I have been surprised to note from the replies of patients who were treated ten and fifteen years ago the large proportion who have outlived the husbands that brought them to me.

---

* Read before the Philadelphia County Medical Society, April 13, 1904.

The proportion of total disappearance of the tumor—18 out of 110 cases—is, I believe, larger than has been reported elsewhere. Some of these instances have not been personally verified by me, and are merely reported as the patient's opinion, but in several instances I have verified the total disappearance of growths which were originally as large as an adult head, or even larger. As for the practical aspects of the patient's opinion of the disappearance in the cases not verified, I may say that, if the person most concerned can not find the harmless remnants of the absorptive process, who need look for them?

No one, surely, would doubt the wisdom that inspired this method when questioning these cured patients, including both those in whom a harmless remnant may be found and those anatomically cured, for it will be hard to realize that these healthful individuals were once confronted with the dreadful verdict of leaders in our profession which prescribed a dangerous and unsexing operation as the only alternative to death, or at least to permanent illness.

Turning to the question of the selection of cases for this method, these statistics teach that hemorrhagic cases are always cured of their dangerous symptoms, the hemorrhages ceasing and the tumors usually decreasing satisfactorily. The interstitial type is also peculiarly susceptible to the treatment and frequently is entirely absorbed.

Those least adapted to it are the pedunculated subperitoneal type; the hard, monocentric, ball-like inclusions in the uterine wall; and those associated with purulent accumulations in the appendages. Whether these should be removed by hysterectomy depends on the amount of suffering or deformity produced by them. The list summarized in this paper includes one case of intrauterine cystic tumor that was cured absolutely by a modification of the Apostoli treatment, but it may be stated that cystic myomata, or any other form of degenerative fibromyoma, should be removed by hysterectomy when practicable. This was impossible of safe accomplishment in the case referred to, in the opinion of the surgeons who sent her to me, and the somewhat hazardous method of treatment by intrauterine bipolar electrolytic destruction with strong currents finally resulted in complete disappearance of the growth and full restoration of health.

CONCLUSIONS.

1. A prolonged observation of cases of fibroid tumors of the uterus under the Apostoli treatment teaches that three-quarters of the cases subjected to the method will be practically cured, as attested by inquiries made from three to sixteen years after the cessation of treatment.

2. The cases that responded poorly, or not at all, to this treatment are not harmed by it, when properly applied, and heroic measures may then be adopted with the certainty that milder means are of no avail.

3. Hemorrhagic and interstitial fibroids are best adapted to the Apostoli treatment, while subperitoneal or degenerative fibroids and those complicated with pyosalpinx are least adapted to be relieved by it.

4. So far as my inquiries and circulars show, there have been but seven deaths among these 110 patients during the sixteen years or less that they have been under my observation. It is an interesting fact, moreover, that but one of these deaths was due to the progress of the growth itself, proving the non-mortal character of this affection. Of the remaining six, one died long after treatment of an affection totally unconnected with the growth, one of septicemia under electric treatment as related, and four while being operated on with the knife.

COMPLICATIONS AND DEGENERATIONS OF UTERINE FIBROMYOMATA.

A PATHOLOGIC AND STATISTICAL STUDY OF TWO HUNDRED AND EIGHTY CASES.*

ELLICE M'DONALD, M.D.
Assistant Resident Physician, Lying-In Hospital of the City of New York; Late Voluntary Assistant, Bender Laboratory, Albany, N. Y.
(From the Bender Laboratory, Albany, N. Y.)
NEW YORK CITY.

INTRODUCTION.

Recent discussions in the surgical and gynecologic branches of the American, British and French medical organizations indicate a renewed interest in the question of treatment of uterine fibromyomata. This is due largely to facts brought forth as the result of the systematic routine pathologic examination of all fibroid tumors. The frequency with which fibroid tumors present degenerations and are accompanied by complications has upset the classical teaching in regard to prognosis and treatment of these growths. More particularly has interest been stimulated in regard to the so-called "malignant degenerations," as is evidenced by the prominent place which carcinoma and sarcoma occupy in recent publications on myoma. At present, however, the results of pathologic studies are not definitely collected, and there is a lack of statistical comparison. The importance of bringing together such results is evident, for the question of operative interference and extent of operation must depend on information derived from combined clinical and pathologic reports. In regard especially to the extent of operation are the results of pathologic investigation of value. While in the removal of a benign tumor it is without doubt ideal that the patient should suffer as little mutilation as possible, still that operation must be done which offers the least danger, and at the same time takes into consideration the various attendant complications. On this point recent investigations indicate that the complications of myomata are by no means to be lightly considered. Aside from the tumor itself, the adjacent organs must be taken into account.

The question of the condition of the ovaries is important from the fact that in supravaginal hysteromyomectomy the trend of opinion among gynecologists is that an ovary should be left in order to ameliorate the severe menopausal symptoms sometimes produced by complete ablations. For this reason the microscopic study of these organs is important in order to determine the frequency of disease of the ovary in connection with myoma.

Also, after hysteromyomectomies and myomectomies, the possibility of infection from a diseased tube is of importance, not only as concerned with the union of the wound, but also as regards the mortality of these operations. Hence the examination of the tubes for salpingitis, pyosalpinx, etc., is of no slight value.

In the study which is here presented, an attempt has been made to determine the frequency of the various degenerations and complications and to base thereon certain general conclusions concerning treatment.

---

* Read before the Philadelphia Obstetrical Society.

GENERAL LITERATURE.

Since Martin[1] in 1888 made his study of degenerations in 205 cases of fibromyomata, others have reported similar series, notably Noble,[2] 258 cases; Cullingworth,[3] 100 cases; Mary Scharlieb,[4] 100 cases, and Frederick,[5] 125 cases. Combined, these make 788 cases available for the classification as to degenerations. There is some slight difference in the classifications of the five writers, but by taking certain liberties with their tables,[6] the degenerations may be summarized as follows:

Fatty degenerations	7
Calcareous infiltration	11
Necrosis	55
Cystic degeneration	34
Telangiectasis	46
Sarcoma	17
Associated carcinoma cervicis	15
Associated carcinoma corporis	17
Myxomatous (edematous)	8
Associated syncytioma[7]	1

(Total number of cases, 788.)

Martin has not estimated his complications; so for the purpose of that classification only the series of Noble, Cullingworth, Mary Scharlieb and Frederick are available. They are as follows:

Appendicitis	13
Hydrosalpinx	41
Hematosalpinx	2
Ovarian cyst	32
Dermoid cyst	5
Ectopic pregnancy	4
Papillary carcinoma of ovary	2
Pyosalpinx	18
Salpingitis	10
Abscess of ovary	7
Tubo-ovarian abscess	1
Dilated ureters and hydronephrosis	1
Dilated ureter, hydronephrosis and pyelitis	1
Parovarian cyst	3
Cystic ovaries	18
Hematoma of ovary	1
Tubercular peritonitis	1
Universal adhesions	22

(Total number of cases, 583.)

In making this complication the difference in classification is more apparent. Frederick and Mary Scharlieb alone make mention of cystic ovaries. Cullingworth in his 100 cases does not mention salpingitis. Many complications of a purely clinical nature, as retroversions of the uterus, etc., have been eliminated in order to bring classification in accord with that of this paper.

In a more recent publication, Daniels[8] in 124 cases found pathologic lesions in the appendages of their immediate neighborhood in 72; in 70 cases of complicated fibromyomata lesions confined to the ovary in 28, tubes in 12, and both in 30.

Marscher[9] in 22 cases of fibromata found ectopic pregnancy in 1 and suppurative diseases of the appendages in 4.

Bond[10] reports 50 cases, in which 8 had tubal disease, which he claims was due mainly to infection from miscarriage.

Hunner[11] in a series of 100 consecutive cases occurring in Kelly's service found pyosalpinx or tubo-ovarian abscess in 6 cases, hydrosalpinx or perisalpingitis in 15 cases and ovarian cysts in 9 cases. There was found in association malignant disease in 7 cases, sarcoma 2, adenocarcinoma of the fundus 3. and squamous carcinoma of cervix in 2.

Other writers have reported smaller series of cases or series devoted to one complication as appendicitis[12] or salpingitis.[13] As these reports do not include all complications they have not been quoted.

From this summary it will be seen that the complications of fibromyomata are many and varied. It will be noted that tubal complications form a very large percentage in Daniel's series, while in the combined series they are not prominent; also in the latter series pyosalpinx is numerically greater than salpingitis. This may, I think, be explained by the fact that the earlier writers did not have a complete microscopic examination of the condition of the tubes. Frederick mentions cystic ovaries which occurred in about 14 per cent. of his cases. Mary Scharlieb estimates ovarian cysts and cystic ovaries together as 23 per cent.

In regard to associated malignant tumors in the combined series, carcinoma occupies a relatively high place. No distinction is made between "sarcomatous degeneration" of a myoma and of sarcoma associated with myoma except in Martin's paper. Of the more recent publications on sarcomatous degeneration of fibroids, Baker and Graves[14] publish 33 cases of fibroid tumors, in which 3 were sarcomatous. The percentage is truly large; but this is similar to the findings of Ulesko-Stroganowa,[15] who reported before the Russian Society for Obstetrics and Gynecology, March 22, 1902, 100 cases of fibromata with 10 cases of malignant degeneration. From the description these are evidently divided into two groups, leiomyoma malignum and true sarcoma. It is not quite clear what is meant by the former. In the discussion which followed, her views were generally opposed. From the abstract of her paper it is impossible to say how many of these were really sarcomatous.

Tate[16] and Bertha Van Hoosen[17] each report a case of sarcomatous degeneration of fibromyoma, which will be referred to later under the special heading.

From these papers it will be seen that "sarcomatous degeneration," while not common, is sufficiently so to merit further study. First, in regard to its frequency, and second, as to whether it is a true transformation of a myomata or merely an associated but independent growth.

[6] In this table associated tumors are arbitrarily included. Martin's 10 cases of suppuration are placed under necrosis. Noble's case of syncytioma is retained, although there is some doubt from the pathologic report as to whether there was a fibroid associated with the new growth. This tumor was twice reported. The following extract is from the second publication, pathologic report by Dr. Babcock: "In the early description of the growth it was described as a sarcomatous or endotheliomatous degeneration of a fibroid tumor; but restudy gives no evidence that fibromuscular tissue is present more than would accompany the growth of the syncytial tumor. It is believed that this is a primary syncytioma malignum in a uterus not the seat of any other tumor."

MATERIAL.

The material on which this study is based[18] represents seven years' service of a general hospital (Albany Hospital), and includes all myomata removed during that time. Complete gross and microscopic examinations have been made in all cases. The series also includes 26 cases in which myomata were found at autopsies.

SUMMARY OF 280 CASES OF FIBROMYOMATA.

Character—	
Single	110
Multiple	170
Small	79
Medium	59
Large	90
Very large	43
Subserous	67
Interstitial	85
Submucous	23
Combined	105
Degenerations—	
Slight hyaline	18
Moderate hyaline	32
Marked hyaline	19
Hyaline and calcareous	8
Calcareous	14
Calcareous, necrotic, hemorrhagic	2
Cystic	8
Myxomatous	4
Hemorrhagic	6
Necrotic	4
Necrotic and hyaline	3
Necrotic cystic infected	1
Adenomyoma	6
Associated with adenocarcinoma	6
Associated with squamous cell carcinoma of cervix	2
Sarcoma	3
Deciduoma malignum	1
Complications—	
Ovarian cysts	15
Parovarian cysts	2
Cystic degeneration of ovaries	55
Tubo-ovarian cyst	1
Calcification of ovary	1
Ovarian fibroma	2
Ovarian carcinoma	2
Salpingitis	38
Salpingitis and hydrosalpinx	3
Salpingitis and tubo-ovarian abscesses	3
Pyosalpinx	5
Pyosalpinx and tubo-ovarian abscesses	2
Extra uterine pregnancy, salpingitis and hydrosalpinx	1
Hydrosalpinx	6
Hydrosalpinx and tubo-ovarian abscess	1
Autopsies—	
Total number	26
Deaths due to tumor	2

PATHOLOGY.

(*a*) *Character.*—All these variations in fibroid tumors are familiar to operators and pathologists. "Multiple" in this series is taken to mean more than one tumor. The division as to size has been based on the following scale: Small, up to 4 cm.; medium, 4 to 8 cm.; large, 8 to 16 cm.; very large, above 16 cm. in diameter. In multiple tumors the diameter of the largest tumor was taken as the determining factor. The largest tumor noted was 90 pounds, and measured roughly 50x40x20 cm. The tumor was single, showed considerable necrosis and calcareous degeneration, and caused pressure symptoms which brought on the death of the patient. It was removed postmortem. Several other tumors were noted between 40 and 50 pounds. It will be noted that 142 tumors measured more than 8 cm. in diameter.

The analysis as regards position was not easy, as it is not always plain into which of the classes a tumor should go. I regret that there is excluded a most important class of broad ligament fibromyomata, of which the data at hand would not allow a proper estimation.

By "combined" is meant multiple tumors, one each of which may be classed in one of the divisions. Thus it is seen that there are 65 multiple tumors which fall into one class (always interstitial or subserous), and 105 multiple which fall into at least two classes.

In one case of multiple fibromyomata a medium-sized fibroid has become detached from its pedicle and lay retroperitoneally being nourished by the mesenteric vessels. Similar cases have been reported by Alban Doran[19] and others.[20]

The comparative infrequency of submucous myomata is noticeable.

(*b*) *Simple Degenerations.*—In tumors of such size (142 above 8 cm. diameter) it is remarkable that a large number with degeneration, particularly with hyaline degeneration, was not met with. The combination of hyaline and calcareous degeneration in eight cases is of interest. It would seem that the tendency of the life-history of these tumors is to undergo progressive hyaline change going on to calcareous degeneration.

The 23 examples of calcareous degeneration existed in old women, one being below 50. These varied in consistence from those of the "Wombstone" type, 10 cm. across, to those with discrete, moderate calcareous deposits.

In the consideration of cystic degeneration, as Alban Doran[21] shows, a distinction should be made between true cystic degeneration and necrosis going on to cavity formation. In this series, however, his standard of judgment that a "fibroid is not truly cystic unless it includes a cavity containing half a pint of fluid," has not been adhered to, but tumors with smaller cavities have been judged as truly cystic. There were no cysts of large size found, the largest containing approximately 1,000 c.c. of fluid. Cystic degeneration is more especially interesting from the fact that of Graves' 4 cases of cystic degeneration 3 were sarcomatous, evidently a necrosis going on to cyst formation. Mary Scharlieb's series shows 6 cases of sarcomatous degeneration, and of these 3 were cystic.

(*c*) *Necrosis and Inflammation.*—All stages of inflammation and necrosis were noted. Necrosis occurred mainly in large subserous tumors, and was evidenced, on section, by brownish-yellow areas. There was usually considerable edema associated. In 4 cases this went on to liquefaction of the central area. It is interesting to note in regard to the possibility of infection that 2 cases were associated with salpingitis and 2 with hydrosalpinx. One large submucous tumor with multiple interstitial nodules was necrotic and sloughing. In all cases of sarcomatous degeneration, hemorrhage and necrosis were noted.

(*d*) *Adenomyoma.*—The percentage of these tumors is about that usually found. They offered in this series nothing of special remark in the gross appearance. One showed marked hyaline change and one calcareous degeneration.

(*e*) *Malignant Changes.*—Sarcomatous degeneration was found in 3 cases. There was no definite appearance by which these sarcomatous changes could be recognized. The main characteristics were necrosis, with broken-down areas and discolored spots from recent and old hemorrhages. A yellowish-white glistening growth could be distinguished in one case infiltrating the muscle and surrounding the necrotic areas. During the period from which these reports were taken, 6 cases of sarcoma of the uterus occurred, in addition to these 3 cases of sarcomatous degeneration of uterine fibroids.

---

[18] I wish to express my thanks to the operators from whom these cases came, more particularly to the surgeons of the Albany Hospital. I also wish to express my gratitude to Dr. Blumer, late director of the Bender Laboratory, and to his assistants, whose conscientious routine examinations and exhaustive records have made this report possible. I also wish to express my sincere thanks to Dr. R. M. Pearce, present director of the laboratory for constant assistance and encouragement.

[21] Doran, Alban H. G.: Fibroids of the Uterus and Its Ligaments, Lecture III, The Lancet, 1903, vol. i, No. 8, p. 497.

In Case 1 it was possible to make a diagnosis in the gross specimen, as the disease had infiltrated the uterine tissue and gave a seminecrotic appearance with irregular hemorrhagic pinkish areas devoid of fibrous arrangement, and a shell of malignant tissue infiltrating the tumor.

Cases 2 and 3 were also necrotic, soft and friable, and in the macroscopic examination were taken for necrotic fibroids.

Chorio-epithelioma infiltrated one case of fibroid tumor. This is, so far as is known, the first authentic instance of such invasion reported. Complete reports of these four specimens from the records of Bender Laboratory follow:

Case 1.—Mrs. M. N. Specimen consists of uterus with tubes and ovaries. One tube and ovary are separate from the rest of the specimen, the tube having been amputated at the junction with the uterus.

Uterus.—The uterus is greatly enlarged and measures 19 cm. long and about 14 cm. in diameter. Except for an irregular area about 7 cm. in diameter corresponding to the fundus, the peritoneal surface is everywhere covered with firm adhesions. Near the superior surface of the fundus are two globular tumor masses the size of a cherry, which are attached to the body of the uterus by a slender pedicle of peritoneum and fibrous connective tissue. Near the above tumor can be seen a pea-sized submucous tumor similar to the above. On section these tumors are pearly white with fine whorls of connective tissue. Adjacent to the origin of the attached tube projects a tumor mass about 3½ cm. in diameter which is soft and on section shows a thin capsule with central contents similar to that of the cavity of the uterus. On section the cavity of the uterus is found to be filled with a necrotic mass, the core of which is the size of an orange, and of a pinkish, yellow color with the consistency of liver tissue. This central mass shows whorl-like markings suggesting the cross-section of a large fibromyoma. Extending from the central core and infiltrating into the muscular coat is a stratum of extremely friable tissue from 2 to 4 cm. in thickness. This stratum is throughout seminecrotic and shows irregular hemorrhagic areas, while at the outer border is an irregular zone which on section presents a jelly-like whitish glistening surface. The muscular coat of the uterus is under considerable tension, retracting rapidly when cut. This muscular coat has an average thickness of about 5 mm., but in many places is not over 2 mm. in thickness. The boundary between the muscular and semi-necrotic mass is nowhere sharply drawn, so that the muscular coat appears to be infiltrated by the mass lying beneath it. Near the fundus of the uterus, the muscular wall is much thicker than elsewhere. On section there is disclosed a definitely encapsulated tumor mass the size of a hen's egg which readily separates from the capsule and presents on section a soft, dark red, irregularly mottled surface. It is connected by a broad isthmus to the mass occupying the cavity of the uterus.

Tubes.—The attached tube is markedly congested, but otherwise apparently normal. Opposite tube is the same.

Ovaries.—The attached ovary is cystic throughout, having numerous cysts ranging from the size of a pigeon's egg to that of a pea, the substance of the ovary being crowded to one side. Opposite ovary shows very many cysts ranging from 2 to 10 cm. in diameter. These cysts contain clear straw-colored fluid.

Anatomic Diagnosis.—Sarcoma of uterus with necrosis and hemorrhage.

Microscopic Description.—Tissues, uterine wall, ovary, polypoid tumor described in gross description. Uterine wall: Sections taken through portion described as capsule in gross description show smooth muscle infiltrated with masses of spindle-shaped cells having large clear staining vesicular nuclei and little protoplasm. Among these cells are seen large irregular cells, the nuclei of which have a lobulated outline. Indistinct mitotic figures are seen in some of the cells. These cells have an utterly lawless arrangement, and deeper in the sections they form a continuous mass containing numerous thin walled blood vessels. Many of the sections show hemorrhagic areas with red blood corpuscles in various stages of degeneration. Some sections show simply masses of necrotic cells.

Polypoid Tumor.—Body of tumor shows smooth muscle largely replaced by fibrous tissue, while the pedicle of the tumor is seen to be infiltrated with cells similar to those described in tumor of the uterine wall.

Ovary.—Shows large follicular cysts and corpora lutea undergoing organization.

Microscopic Diagnosis.—Uterus with fibromyomata invaded by spindle-celled sarcoma; necrosis; hemorrhage; follicular cysts of ovary.

Case 2.—Miss S. A. T. Specimen consists of an irregular mass of tissue composed of uterus and appendages and measures 18x13x7 cm. At one portion is attached a normal fallopian tube, which measures 11 cm. in length, and an ovary 1x2x2½ cm. which has undergone fibrous change. On section the irregular surface of the mass is found to be due to the presence of large, roughly spherical tumors, varying in size from 2 to 11 cm. in diameter. The original form of the uterus can not be made out. The cavity of the uterus is pale and covered with a somewhat sticky secretion. The tumor masses which lie in the myometrium, on section, have the characteristic appearance of myomata; one of the large tumor masses has undergone degeneration, is soft and friable, and contains a considerable amount of blood. Immediately beneath the serous coat are a number of small pedunculated tumor masses which average 1 cm. in diameter. On section these are similar to the large tumor masses.

Anatomic Diagnosis.—Multiple interstitial and subserous myofibromata of the uterus. Normal fallopian tube. Fibroid ovary.

Microscopic Description.—In places a definite picture of fibromyoma may be seen. Adjacent to such areas and differentiated from it only by the difference of structure, are areas of typical spindle-celled sarcoma. The sarcomatous tissue is extensively necrotic, the necrosis in places being universal, and in other places sparing the cells immediately about the vascular channels. The necrotic areas are infiltrated with leucocytes. Necrosis is seen as well in the myomatous portion, but is not so prominent.

Microscopic Diagnosis.—Fibromyoma invaded by spindle-celled sarcoma.

Case 3.—Mrs. S. E. Specimen consists of about 25 separate pieces, which in aggregate make a mass about the size of a man's hand. One large globular mass measuring about 18 cm. in diameter makes up the bulk of the specimen. This mass presents a convex smooth surface covering about three-fifths of the mass. This surface is smooth, pale pink in color, part of surface being glistening and part of it showing firm, blood-stained connective tissue bands. The remaining periphery of this mass is exceedingly irregular and consists of various sized strips of tissue which are soft, friable and deeply stained and show numerous large blood vessels. The contents of many of the blood vessels consist of firm coagulum. These shaggy strips are distinctly necrotic and are undoubtedly further represented by the numerous small pieces of semi-necrotic material which go to make up the remainder of the specimen. The comparatively smooth surface of this mass is irregularly lobulated and shows beneath the surface a number of small cysts filled with a clear amber-colored fluid, also numerous pea-sized to cherry-sized spherical tumor masses, some of which present on cross-section a pearly white glistening surface with a whorl-like arrangement of the tissue elements. On section of the large tumor mass, the cut surface presents a thin cortex varying from 2 to 10 cm. in thickness composed of a firm, pinkish-white tissue beneath which is a whitish, coarsely granular surface showing the remains of numerous small cysts, most of which are filled with a blood-stained fluid. As one gets farther away from smooth surface the section becomes considerably blood stained and takes on a yellowish necrotic look and the cysts become larger in size until finally the semi-necrotic shredded mass described above is reached. The small pieces accompanying this specimen consist of stringy masses of distinctly necrotic tissue similar in character to that described as occurring in the center of the large tumor mass. One of the larger pieces accompanying the specimen is thin, averaging about 1 cm. in thickness, has on smooth side considerable adipose tissue and resembles in consistency on cross-section the firm tissue described as forming the capsule in the main tumor mass. No evidence of tubes and ovaries.

Anatomic Diagnosis.—Degenerated fibroid of uterus.

Microscopic Description.—Sections through portion described as capsule of large tumor show thin layer of smooth muscle tissue with invading masses of medium-sized cells having rather darkly-staining oval or spindle-shaped nuclei and little protoplasm. Many irregular mitotic figures are seen among these cells. The deeper, softer portions of the tumor are seen to be composed of solid masses of these cells. Numerous thin-walled blood vessels are seen in the cell masses. No evidences of necrosis are seen. Many blood vessels at the periphery of the tumor are completely plugged with the tumor cells. Sections through nodular masses at surface of tumor show smooth muscle tissue rich in cells and a moderate amount of fibrous tissue.

Microscopic Diagnosis.—Myoma of uterus invaded by spindle-celled sarcoma.

Case 4.—Mrs. C. R. Specimen consists of an enlarged uterus measuring 11x6x5 cm. Peritoneal surface is smooth. The Walls are for the most part normal. At one point there is a typical myoma one centimeter in diameter, with a hemorrhagic center. Springing from the mucous membrane there are a number of cauliflower-like excrescences over areas varying from 1 to 2 cm. in diameter. These project .5 cm. above the surface of the mucosa, some of them ulcerated, covered by little papillary projections and distinctly hemorrhagic. On section they appear to be part of the new growth which extends down into the uterine musculature. This growth is for the most part distinctly hemorrhagic, though in one or two places of a homogeneous white color. In the uterine musculature of the fundus is a small cavity, about a centimeter in diameter, into which projects a number of pinhead-sized, congested, papillary excrescences.

Anatomic Diagnosis.—Adenocarcinoma of the uterus (?). Small interstitial myoma.

Microscopic Description.—Section presents a small piece of typical fibromyoma, at one side of which is a large hemorrhagic mass. The line of separation and blood clot is not distinct. The adjacent portion of tumor shows some lymphocytic infiltration. This hemorrhagic mass shows throughout some necrotic tissue with irregular strands and masses of syncytial tissue composed of cells with a large amount of protoplasm and large deeply staining nuclei. The outlines of these cells are not always distinct owing to the fusing of their protoplasm. The syncytial cells are found everywhere in the midst of hemorrhage. The necrotic tissue is moderately infiltrated with leucocytes. The nuclei of the large cells are often irregularly stained, sometimes are so arranged as to give the appearance of giant cells. These masses are in direct continuity with the myoma; in several places a distinct invasion is evident.

Microscopic Diagnosis.—Fibromyoma of the uterus infiltrated with chorio-epithelioma.

(*f*) *Relation to Cancer.*—Adenocarcinoma of the fundus was associated with fibroid tumor in six cases, in two of which the fibroid was infiltrated by the carcinomatous tissue. In five of these cases the uterus was the host of interstitial fibroids of small or medium size. When the relative frequency of adenocarcinoma and squamous carcinoma is considered. it will be seen that we have here a much higher percentage of adenocarcinoma than is found in the usual run of cancer cases complicated and uncomplicated by fibroids. This agrees with Martin's estimation.

Squamous carcinoma of the cervix occurred in two cases. In both cases the fibromata were interstitial and very small.

In view of the relative *frequency of adenocarcinoma* and fibromata of the uterus, it would seem that the association of the two are worthy of consideration. If the percentage of fibroids at autopsies, 14.8 per cent. (*v. infra*), be taken as an approximate ratio of their occurrence, it seems at least that while the association of squamous carcinoma with fibroids is accidental, the occurrence of adenocarcinoma *may* be more or less influenced by the presence of fibroid tumors. In this connection statistics compiled from the records of institutions having large series of cases and autopsy reports would be of value.

(*g*) *Complications.*—(1) Ovarian cysts occurred in 13 cases and varied in size from 6 to 12 cm. in diameter, but one was of the papillomatous type. Seven of these cases were additionally complicated by salpingitis.

The two parovarian cysts were of moderate size, about 6 to 8 cm. in diameter. One tubo-ovarian cyst existed, and was of moderate size.

The ovarian fibromata measured 8x7x4.5 and 20x11x10 cm., respectively. The latter was associated with a very small interstitial fibroma of the uterus. Of the two cases of carcinoma of the ovary, one was bilateral, and in both instances the growths were due to metastases from a tumor of the breast.

Cystic ovaries (one or both) in 55 cases (20 per cent.) may seem to be a large percentage, but compares very closely with Scharlieb's[4] estimation of this complication. These are due, it is thought, to the undue thickness or toughness of the ovarian boundaries. There is in almost all these ovaries an increase in the amount of fibrous tissue.

(2) *Tubal Complications.*—The tubes were diseased in 60 cases; of these 38 were salpingitis alone. In several cases the gross change was slight and the diagnosis made microscopically. In 12 cases there was pus in the appendages in the form of pyosalpinx or tubo-ovarian abscess. There were also 11 cases of hydrosalpinx. of which 5 were additionally complicated by salpingitis, tubo-ovarian abscess or ectopic pregnancy. One case combines *all three—ectopic pregnancy*, salpingitis and hydrosalpinx.

(3) It will thus be seen that the ovaries, tubes and adjacent neighborhood were diseased in a large number of cases. Alban Doran states that his experience is more like that of Cullingworth. who found no disease in the appendages save 5 cases of hydrosalpinx in 100 fibroids. Lawson Tate and Twambly,[22] on the other hand, imply that this condition exists in 50 per cent. of all cases of fibroids. Daniels (*v. supra*) found disease of the appendages in 58 per cent. of his cases. In this series (including 55 cases of cystic ovaries) the appendages showed disease in 137 cases, or 49 per cent. In addition to these cases there were many cases in which the remains of adhesions were noted, but as it was obviously impossible to estimate this with exactness, without description of the appearance *in situ* at the time of operation, this complication has not been noted.

(*h*) *Myomata in Routine Autopsy Work.*—On examination the records (Bender Laboratory) of autopsies on women show that fibromyoma of the uterus was found in 26. In two cases apparently death was indirectly caused by the tumor. To what extent the intercurrent disease, which was the cause of death in other cases, was hastened in its course by the associated fibroids, can not be deducted. The tumors were large in 3 (greater than 8 cm. diameter); small in 20 cases (less than 4 cm. diameter), of these last 10 were single and 10 multiple. The ages at which these patients died in decennial periods were as follows: Under 35, three; between 35 and 45, six; between 45 and 55, six; between 55 and 65, six; between 65 and 75, four; above 75, one. The youngest was 28; the eldest 78. The influence of the tumor was apparent in one case in which death was due to anemia and nephritis; a large submucous tumor by pressure had caused hydroureter and uterine hemorrhages. In a second case a large fibroid tumor of 90 pounds by pressure had caused hydroureter and various congestion with edema of lungs. In this case the weight of the woman less the tumor was 65 pounds. The other cases, which were probably influenced by the fibroid tumor, are deaths from pyonephrosis, pyelitis, rupture of bladder and acute peritonitis. Bishop[23] has collected 37 fatal cases of fibromyomata.

---

[22] Bishop, Stanmore: Uterine Fibromyomata, p. 49.

Of the 20 small tumors, one was complicated by tubo-ovarian cyst and hydrosalpinx. Four were associated with adhesions, and one with carcinoma of the ovary secondary to mammary cancer.

Of the medium-sized tumors, of which there were three, one was associated with bilateral pyosalpinx which had caused a general peritonitis. The tumors in this case were three in number and interstitial.

The total number of autopsies done on women over 20 years of age during the seven years in which these autopsy reports were collected amounted to 175. So that of all adult women coming to autopsy, 14.8 per cent., or one in every seven, had uterine fibroids. From this it may be seen that small fibroids of the uterus may cause little or no disturbance, and that many of these tumors cause no symptoms and are not discovered during life. The danger of these growths, apart from submucous tumors, is due to their complications, and while these may not always endanger life, it is evident that they frequently cause sufficient disturbance to produce alterations in the surrounding tissues, as is shown by the presence of adhesions, etc.

RELATION OF PATHOLOGIC CHANGES TO TREATMENT.

In conclusion, what deductions can be drawn from this series? So much has been written by men of wider experience that it would be a work of supererogation to add to their well-debated advice. But there are a few questions to be considered:

First, in regard to the advice we must give to a patient suffering from fibroid. It is well understood that the operation for fibroids, in the hands of capable operators, is in uncomplicated cases practically devoid of danger. It is to complications and degenerations that mortality in fibroid tumors is due, as we know from experience and from published reports. Delay in an uncomplicated fibroid exposes the patient to the possibility of the development of complications. And with the large percentage of complications in this series it is evident that with delay the liability to complication is increased. While this is so, it is evident that there is one class of fibroids which may cause few or no symptoms, viz., the small subserous and interstitial tumors. We may, therefore, say that delay is justifiable only in these latter cases and not justifiable in even these when complications exist.

In reference to the extent of operation, while it is obvious that myomectomy is the ideal operation, there is no doubt that it is only applicable to a small class of cases—those in which the tumors are easily accessible and in which it is possible to eradicate them completely. If eradication is not complete, there is the possibility of renewed growth, and should pregnancy occur, with its increased blood supply, this possibility is the greater. This should be kept in mind, as those cases in which myomectomy is desirable are usually childless women.

It is at present accepted that the operation of supravaginal hysteromyomectomy[24] is accompanied by the lowest mortality.[25] But this operation is obviously not applicable to those cases with malignant degeneration and associated with malignant disease of the uterus. Such cases demand complete extirpation of the cervix. Should, however, the commonly accepted operation of supravaginal hysteromyomectomy be attempted, and on opening the uterus adenocarcinoma or suspicious necrotic change be seen, the cervix may be removed and a complete ablation done.[26]

Adenocarcinoma and sarcoma are the forms of malignancy which, in connection with fibroids, are most likely to come to operation unrecognized. If, however, the case be uncomplicated by malignancy, the choice must lie between amputation through the cervix and myomectomy. It is rarely advisable to do myomectomy when the appendages are adherent or in the presence of old or recent infection. The site of enucleation may become the starting point for a peritonitis.[27] In view of the large percentage (21.4) of diseased tubes, it is evident that myomectomy is limited to a small class of cases.

Should amputation through the cervix be the operation of choice, one or both ovaries may be left to ameliorate the symptoms of the surgical menopause. In such case not only must the question of infection from the tubes be considered, but also the condition of the ovary to be left. In a large percentage of this series cystic ovaries were found. A cystic ovary should not be left; if necessary, resection may be done and the cysts removed.

CONCLUSIONS.

1. Fibroids which are producing symptoms, and all fibroids except those designated as small (especially when subserous or intramural), should be removed, because the risk to the patient from operation is far less than that from the tumors themselves.

2. In view of the sarcomatous changes, carcinomatous associations and complications of uterine fibromyomata, early removal is indicated when they are of sufficient size to produce symptoms. Small uncomplicated tumors not producing symptoms do not require early treatment.

3. Thorough pathologic examination should be made of all fibroids for evidence of malignancy. Particular study should be devoted to those tumors which are necrotic, cystic or both, as among these are found the largest proportion of malignant changes.

THE TREATMENT OF FIBROID TUMORS OF THE UTERUS.*

CHARLES P. NOBLE, M.D.
Surgeon-in-Chief Kensington Hospital for Women.
PHILADELPHIA.

When I addressed the British Gynecological Society[1] in 1901 on the subject, "The Complications and Degenerations of Fibroid Tumors of the Uterus as Bearing on the Treatment of These Growths," reporting 218 cases, it was with the purpose of pointing out that, in my judgment, the profession had not had a proper estimate of the natural history, degenerations, complications and dangers of fibroid tumors. At that time no one had considered this subject from the standpoint in question. Martin, 1888, had written a paper[2] reporting the degenerations in the tumors themselves, but ignoring the complications which existed in the particular cases reported. But from 1888 until 1901 the literature shows that no special attention had been paid to this subject, and that the complications of fibroid tumors had attracted practically no attention whatever. It can not be otherwise than gratifying to me that following my own paper on the subject there have been a number of very valuable and careful reports of the individual experience of other surgeons in this field. This is particularly true of the papers of Cullingworth,[3] Frederick,[4] Scharlieb[5] and Hunner.[6]

The conclusions of my paper[7] of 1903, reporting 258 cases of fibroid tumor, were as follows: It was estimated that because of the degenerations present, 16 per cent. of the patients would have died without operation, and that because of the complications present, 18 per cent. would have died without operation, or a total of 34 per cent. In addition to this a certain number of the patients would have died from intercurrent diseases contracted because of the reduced state of health of the patient; in other words, that more than one-third of the women having fibroid tumors which had come under my observation would have died had they not been submitted to operation.

At this date (Jan. 31, 1904) I have operated on 278 patients having fibroid tumors of the uterus. A table of the complications and degenerations encountered in these cases follows. In 180 cases complications or degenerations were present, and in 98 cases no degenerations or complications were recorded. There is no doubt that a good many of the simpler complications and degenerations were not recorded, more especially in the early work. This applies more particularly to edema and to myxomatous degeneration of the tumors. These cases were looked on at that time as instances of soft fibroids, and no note was made of their pathologic condition.

COMPLICATIONS AND DEGENERATIONS OF FIBROID TUMORS COMPLETED TO JAN. 31, 1904.

Adenocarcinoma of body of uterus	6
Epithelioma of cervix uteri	4
Epitheliomatous infiltration of fibroid tumor arising from adenocarcinoma of corpus uteri by metaplasia	1
Sarcoma	2
Chorioepithelioma	1
Myxomatous degeneration of tumor	8
Cystic degeneration of tumor	7
Calcareous infiltration of tumor	6
Necrosis of tumor	18
Twisted pedicle, pedunculated tumor	2
Intraligamentous development of fibroid	19
Procidentia of uterus	5
Retroversion of uterus	4
Papillary carcinoma of both ovaries	1
Ectopic pregnancy	3
Dermoid cyst, bilateral: umbilical hernia	1
Dermoid cyst, suppurating sinus through abdominal wall	1
Dermoid cyst with twisted pedicle	1
Dermoid cyst	1
Ovarian cyst with twisted pedicle	1
Ovarian cyst, suppurating	1
Ovarian cyst, bilateral	2
Ovarian cyst, unilateral	22
Cystic degeneration of ovaries	5
Abscess of ovary	1
Parovarian cyst	2
Pyosalpinx, bilateral	9
Pyosalpinx, unilateral	4
Hematosalpinx	1
Hydrosalpinx, bilateral	10
Hydrosalpinx, unilateral	8
Salpingitis, bilateral	2
Salpingitis, unilateral	10
Abscess of broad ligament	1
Appendicitis	10
Total	180

It is interesting to compare my own series of cases with that reported by Dr. McDonald.[8] Of his series of 280 cases there were:

Chorioepithelioma	1
Sarcoma	3
Squamous cell carcinoma of cervix	2
Adenocarcinoma	6
Necrotic, cystic, infected	1
Necrotic and hyaline	3
Necrotic	4
Cystic	8
Calcareous, necrotic, hemorrhagic	2

This makes a total of 30 patients who undoubtedly would have died without operation. It is equally certain that a considerable number of the patients having other degenerations would have died.

Of the complications there were:

Ovarian cysts	15
Tubo-ovarian cysts	1
Ovarian carcinoma	2
Salpingitis and tubo-ovarian abscess	3
Pyosalpinx	5
Extra-uterine pregnancy, salpingitis and hydrosalpinx	1

---

[8] McDonald, Ellice: Complications and Degenerations of Uterine Fibromyomata. See p. 1344, this issue.

This is a total of 29 that would have died without operation, giving a mortality of 59 in 280 cases, or 21 per cent. This does not include the mortality which would follow the various degenerations not classed as fatal, nor the various complications not necessarily fatal. When these are added, it would bring the mortality in Dr. McDonald's series approximately to that in my own and to that in Frederick's and Cullingworth's.

As illustrating the way these cases run: Since September 15 I have operated on 13 cases, the complications of which are as follows:

1. Salpingitis, submucous fibroid previously removed.
2. Uncomplicated.
3. Adenomyoma.
4. Uncomplicated.
5. Uncomplicated.
6. Calcareous infiltration.
7. Uncomplicated.
8. Left hydrosalpinx, right salpingitis.
9. Bilateral pyosalpinx.
10. Adenocarcinoma of body of uterus.
11. Necrotic tumor, adenocarcinoma of body of uterus.
12. Abscess of broad ligament, bilateral salpingitis.
13. Submucous fibroid, sloughing.

This group of cases occurring in three months and a half illustrates the erroneous nature of the old view concerning the innocence of fibroid tumors. Or, to put the matter in a more correct way, it illustrates the fact that women having fibroid tumors are, as a rule, sick women, who have not only fibroid tumors, but other conditions, the complications often being even more serious than the tumors themselves.

Dr. McDonald's tables, those of Cullingworth, Frederick and my own, show the folly of the classical view that women having fibroid tumors of the uterus, as they come under the observation of the gynecologist, are practically well women, suffering but few or no symptoms, and running but little risk as to their health or as to their life. It is begging the question to change the classification and to assert that these women are sick merely because of the complications. The change in classification does not alter the fact that the women having the fibroid tumors, as they come under observation, are usually sick women. As I have presented this subject before several medical bodies already, I am aware of the objections to the point of view which I hold, and of the statements and arguments of those who claim to be conservative (using the term in its debased instead of its primary sense) in the treatment of fibroid tumors. As a matter of fact, I believe that these men operate on these cases with cheerful alacrity, but base the indication for operation on the particular complication which may be present. Many of the complications, so far as concern their risks to health or to life, are trifling as compared to the risks of a fibroid tumor. For example, such complications as a parovarian cyst, a retroversion of the uterus with or without adhesions, or cases of appendicitis which have recovered from the acute attack (the so-called interval operation). Every surgeon operates on such cases, although the gravity of the lesions is trifling as compared with the gravity of a fibroid tumor. Patients in whom the tumors are not complicated by other conditions are operated on, as alleged, because of the symptoms which are present—hemorrhage, pain, the presence of a tumor, pressure on the urinary organs or on the alimentary canal, etc. For example, in my table of 278 cases, 180 would be operated on because of the complications present, and the remaining 98 would be operated on because of hemorrhage, pain, the presence of the tumor or pressure on the urinary organs or on the alimentary canal. That is to say, the form of words used in stating the indication for operation does not alter the fact that these cases are operated on by surgeons and gynecologists at the present time as a routine matter of practice.[9]

Another point to which I wish to call special attention is the relation of fibroid tumors to malignant degeneration and especially to adenocarcinoma of the body of the uterus. In Martin's group of 205 cases there were reported:

Sarcoma of tumor	6
Carcinoma of cervix uteri	2
Carcinoma of corpus uteri	7

---

[9] Although the position I have taken, with reference to the nature of the indications for operation for fibroid tumors in the various contributions which I have made to the subject, seems to me entirely clear, those who maintain the classical or traditional attitude in their public discussions on the subject have constantly confused it or failed to appreciate it. In order that there may be no doubt about the matter I shall state it in formal terms. The carefully gathered facts with reference to the life history, the degenerations and the complications of fibroid tumors which are presented in this paper, and have been presented in the previous papers, show that about 16 per cent. of women having fibroid tumors would die if not operated on because of the degenerations and complications arising in the tumor or in the uterus; in other words, that the women having fibroid tumors run a far greater risk of losing their lives by not having them operated on than by submitting themselves to operation. In addition it has been shown that women having fibroid tumors as they present themselves to the gynecologist have, in addition to the tumor itself, many complications outside of the tumor and the uterus. Of the women having fibroid tumors, who have come under my observation, about 18 per cent. would have died without operation because of the complications outside of the tumor and the uterus. This state of facts forms a secondary but an additional reason for operating on women having fibroid tumors, taking them as a class. Taking them as a whole, at least one-third of the women having fibroid tumors, who have come under my observation, would have died had they not been operated on. I hold that the scientific position in reference to the indication for fibroid tumors is that as these facts are incontrovertible—being based on careful clinical and pathologic investigation—that the indication for operation should be based on these facts and not on any particular symptom which may be present at the time the woman comes under observation. My position is distinctly in opposition to that which may be called the classical or traditional position, which is, that the operation to remove a fibroid tumor should be done because of the symptoms it is producing at the time the patient presents herself for treatment—whether this be hemorrhage or pain or pressure on the urinary organs, or on the alimentary canal, or whether it is a state of the mind arising in the woman because of her knowledge of the existence of the tumor. Nothing is more variable than symptoms, which can frequently, and indeed, usually, be removed by appropriate treatment. Indeed, the state of the case is even worse than this, for most symptoms it is necessary to take the patient's statement. On the other hand, nothing is more definite than physical facts and pathologic findings. When the two positions are placed in opposition it seems to me there can be no question as to which is the correct one and which should be accepted by the profession. To speak by analogy, a fibroid tumor should be removed for the same reason that an ovarian tumor should be removed; the indication varying in degree, but not in kind. Ovarian tumors are removed, irrespective of the symptoms they are producing, because of our knowledge of the life history of these growths, which is, that if left to pursue their usual development a fatal result will occur in almost all cases. Similarly, fibroid tumors should be removed, because if left to pursue their usual development, at least in one-third of the cases a fatal result will occur.

For those who are convinced that the classical position is correct, I would suggest that one of the strongest arguments that could be produced in support of their position would be to institute a careful research into the autopsy records of well managed institutions in order to learn, first, in what proportion of women fibroid tumors are found at autopsy, and second, what relation these tumors had to the state of health or to the death of the particular patients. It is a classical statement that many women live and die without the knowledge that they have had fibroid tumors. This statement I do not believe, but I would be quite willing to be convinced of its truth on adequate evidence.

It has also been suggested to me that being a gynecologist with a consulting practice, my experience with reference to fibroid tumors is an exceptional one, and that the experience of the family physician is quite different; the difference being that fibroid tumors as he sees them are producing much less mischief than is the case in my experience. At first sight this seems possibly to be a plausible statement. However, I was at one time a family physician myself, and for ten years I had a large experience as attending physician to various dispensaries for the diseases of women, in both of which positions my experience would naturally be the same as that of the family physician. Comparing that experience with that of the present I am able to see no difference whatever; therefore, it is my belief that while this statement sounds plausible, it is incorrect.

In my own experience (278 cases) there have been encountered:

Chorioepithelioma	1
Sarcoma	2
Epithelioma of cervix uteri	4
Adenocarcinoma of the corpus uteri	6

In Frederick's paper, including a series of 125 cases of fibroids, there were:

Sarcoma	2
Epithelioma of cervix uteri	2
Carcinoma of endometrium and body	6

In Dr. Cullingworth's paper, being a series of 100 cases, there was:

Myxosarcoma	1

Dr. McDonald reports a series of 280 cases in which there were:

Chorioepithelioma	1
Sarcoma	3
Squamous cell carcinoma of cervix uteri	2
Adenocarcinoma of corpus uteri	6

This gives a total of 988 cases, in which occurred:

Chorioepithelioma	2
Sarcoma	14
Carcinoma of cervix uteri	10
Carcinoma of corpus uteri	25

It is at once apparent that the adenocarcinomata of the body are much more common in cases of fibroid tumors than are the epitheliomata of the cervix, whereas in general, epithelioma of the cervix is far more common than adenocarcinoma of the body. The usual ratio between epithelioma of the cervix and adenocarcinoma of the corpus of the uterus is as one to three, or four. (Cullen[10] gives 123 cases of squamous cell carcinoma of cervix, 18 cases of adenocarcinoma of cervix, and 35 cases of adenocarcinoma of the body of the uterus.)

The natural conclusion to be drawn from so large a series of cases is that there is a direct causative relation between fibroid tumors and the development of carcinoma of the body of the uterus.

Dr. McDonald states that small fibroid tumors, especially the subserous and intramural fibroids, do not require early operation. From my standpoint this is the only group of fibroids in which this question is debatable. In all other classes certainly, with the knowledge before us at the present time, patients having fibroid tumors should have them removed. With reference to the small tumors which are subserous or intramural, undoubtedly if there is any class of fibroids which do not require removal, it is this group.

The facts drawn from the large series of cases which I have reported not only from my own experience, but from that of Martin,[11] Cullingworth,[3] Frederick,[4] and now from Dr. McDonald's paper[8] (988 cases), make it more than doubtful whether it is conservative (in the primary sense of the word) to advise against the removal of a fibroid tumor in any instance, unless in the particular case there is some good reason, owing to disease in other organs of the body, why an operation would be especially hazardous. An analysis of the various series of reported cases shows the following facts:

	Per cent.
Sarcoma developed in	1.5
Adenocarcinoma of the corpus uteri developed in	2.5
Carcinoma of the cervix developed in	1.0
Necrosis of the tumor occurred in	6.1
Cystic degeneration occurred in	3.4

These facts are incontrovertible; and when added to the probability of the continued growth of the tumor in any special instance and to the probability of various complications arising outside of the tumor and of the uterus, it seems to me clear that anyone having an open mind must be convinced that the conditions surrounding any particular instance of fibroid tumor of the uterus must be exceptional for it to be less dangerous for a woman to retain her tumor than to have it removed by a competent gynecologist.

At the same time, so great is the influence of tradition and so difficult is it to change one's habits of thought, that in this particular group, in spite of my convictions, I have been in the habit of advising expectant treatment. In the not distant future, however, it seems to me very probable that in this group of cases also patients will be advised to have the tumors removed, unless in a particular case there is some good reason to the contrary. It is the general rule in surgery that a tumor when present in the body should be removed, and this is as applicable to fibroid tumors of the uterus as to other tumors.

The evidence which is now available proves conclusively that over one-third of the women having fibroid tumors will die unless the tumors are removed; that the risk of radical operation in uncomplicated cases is very small—probably 1 or 2 per cent.; that in the average of cases, in good hands, it is about 5 per cent., rising to 10, 20 or 30 per cent. in the gravely complicated cases; that, therefore, on the main proposition there is no question but that fibroid tumors should be removed. The debatable ground is whether or not to remove small fibroid tumors, especially when subserous or intramural.

Special Article.

THE ARMY MEDICAL DEPARTMENT.

III.

A HISTORICAL SKETCH.

(Continued from page 1288.)

The admirable medical organization of Letterman disappeared with the armies of Grant and Sherman, and Congress, weary of war, could not be induced to take interest in any military matter, except in the direction of reduction and economy. While all other nations made haste to apply the lessons of our war and to remodel their medical organizations in accordance with them, our own Medical Department reverted to antebellum conditions and went backward. The hospital stewards were the only permanent enlisted personnel and all nursing and other work about the hospitals was done by an uninstructed and constantly changing personnel of men detailed from the companies.

No worse system could have been invented, and yet it lasted 22 years, until, in 1887, the first step toward a modern organization was made by the establishment of a hospital corps, consisting of privates and two grades of non-commissioned officers. The medical officers then began the systematic training of the personnel and the study of modern medical organization with a view to war conditions. This movement unfortunately was misunderstood by the officers of the line and met, especially at first, with much ridicule and covert opposition, the use of military titles by medical officers being especially resented. In 1892 the Army Medical School was established in Washington for the instruction of young medical officers in hygiene, medical administration and other branches of special importance in military medicine. The influence for good of this school has been already marked and is constantly widening, and now that the course has been thrown open by act of Congress to offi-

cers of the organized militia, it needs only larger accommodations in the way of class rooms to become an institution of national importance.

The outbreak of the Spanish War in 1898 found the Medical Department with a personnel of 177 commissioned officers and 750 enlisted men. This number was barely sufficient to perform the medical service of the regular army of 25,000 men in time of peace. When a volunteer army of 250,000 men was mobilized, and at the same time an expedition embracing practically the entire regular army was organized to attack Santiago, it was immediately evident that if the regular regiments were to be cared for by regular medical officers but few would be left to organize the medical service of the volunteer armies. Each of the volunteer regiments brought with it into service three regimental surgeons and three hospital stewards, but no privates. The regimental and field hospitals had to be organized at the expense of this regimental medical personnel. The enlisted strength of the regular hospital corps was inadequate for 25,000 men, and as Congress failed to authorize the enlistment of volunteer Hospital Corps men, the situation in this respect became at once acute, and was only partially relieved by the clumsy expedient of authorizing the transfer of men from volunteer regiments to the regular Hospital Corps. The volunteer surgeons, though in many cases appointed without effective examinations, were, as a rule, capable and efficient physicians, but were lacking in administrative experience, and in practical knowledge of military hygiene. The troops were, in most cases, kept for long periods of time in their camps of mobilization and so the typhoid infection, which almost every regiment brought with it from its state camp, had good opportunities for dissemination.

The typhoid epidemic which swept through these camps is a recent and painful memory, but it is by no means certain, in spite of the remarkable study of these epidemics to be found in the report of Reed, Vaughan and Shakespeare, that the lessons of 1898 have been taken to heart by either the medical or the military profession, or that a reassembling of large bodies of troops would not be followed by a recurrence of these experiences.

The military and sanitary lessons of this war are most instructive and should not be lost. Fortunately they have been studied with much care and patience and every facility for arriving at the truth by a commission appointed by President McKinley to investigate the conduct of the War Department in the war with Spain, commonly known as the Dodge Commission,[1] from the name of its chairman. Their conclusions were:

What is needed by the Medical Department in the future is:

1. A larger force of commissioned medical officers.
2. Authority to establish in time of war a proper volunteer hospital corps.
3. A reserve corps of selected trained women nurses, ready to serve when necessity shall arise, but, under ordinary circumstances, owing no duty to the War Department, except to report residence at determined intervals.
4. A year's supply for an army of at least four times the actual strength, of all such medicines, hospital furniture, and stores as are not materially damaged by keeping, to be held constantly on hand in the medical supply depots.
5. The charge of transportation to such an extent as will secure prompt shipment and ready delivery of all medical supplies.
6. The simplification of administrative "paper work," so that medical officers may be able to more thoroughly discharge their sanitary and strictly medical duties.
7. The securing of such legislation as will authorize all surgeons in medical charge of troops, hospitals, transports, trains and independent commands to draw from the Subsistence Department funds for the purchase of such articles of diet as may be necessary to the proper treatment of soldiers too sick to use the army ration. This to take the place of all commutation of rations of the sick now authorized.

To these should be added the creation of a corps of medical inspectors with adequate rank and powers.

In the reorganization of the Army by the Act of Feb. 2, 1901, no attention was paid to the recommendations of this commission or to those of the surgeon general, and the proportion of medical officers was not only not increased but was greatly reduced, while their prospect of promotion was taken away by disproportionate increase in the lower grades. The defects of this reorganization have been recently recognized by the War Department, and a bill is now before Congress, approved by both the former and the present secretary, for their correction. It will be the duty of the General Staff to secure legislation to carry out the second recommendation and to make such arrangements with the Quartermaster's Department as will secure the fifth. The third has already been provided for and the surgeon general's office is making it a part of its policy to purchase each year, as appropriations permit, the accumulation of supplies suggested in recommendation four. The sixth recommendation is now being considered by a board which will also get up a book of forms which will explain clearly to the uninitiated the preparation of all reports and returns. The seventh recommendation has been already carried out.

The profession has learned that in military camps typhoid fever is certain to appear, and that it is not always, or even most usually, an infected water supply which is responsible for its spread, but that in the Spanish War flies conveyed the infection from latrines to food, and it was also spread in many cases by infected hands, clothes and tent flaps. It has also been learned that in the United States a continued fever which does not readily yield to quinin is in the great majority of cases typhoid fever. But there are other lessons of that war which must be unlearned and precedents which must be forgotten. The great camps of mobilization for the volunteer forces were sedentary commands, and the regimental and field hospitals never learned the limitations imposed by mobility and the question of transportation. No stationary or base hospitals were at first provided near these great camps to receive the seriously ill, and so the field hospitals, and later even the regimental hospitals, were immobilized and anchored down by typhoid cases, and by a great mass of paraphernalia which, while very proper for the care of such cases, was utterly out of place in organizations supposed to be mobile, and to only afford the sick and wounded temporary shelter until they can be sent back to a stationary or base hospital.

With this misconception of the use of the regimental and field hospital has arisen an elaborate equipment which has even been recognized in the medical supply table, with sheets which there is no way of washing, and furniture which can rarely be transported. These should be reserved for the stationary or base hospitals. The true rôle and equipment of the field hospital is admirably described in the words of the late Col. Dallas Bache, assistant surgeon general:

---

[1] The medical member of this commission was Dr. Phineas S. Connor of Cincinnati.

The division hospital, which is the logical unit for medical field service, and will survive the new criticism, has created for itself a picturesque reputation that is destined to make trouble. It has frames, floors, wire mattresses, much bedding, and many conveniences. The hospital of experience is a lean, though active thing, by the side of this opulent hotel. It is for nimble service, and often stripped to the simplest necessities, waterproofs, blankets, and a chance concession for empty bed sacks. It must often ignore tables of supply; it can not afford a superfluous ounce of flesh or anything else. Its transportation must go for its canvas, stores, clothing, utensils, and tools. Its intent is to cover barely, to receive the sick and wounded, but not to harbor them long; to be ready at an hour's notice to move. Furniture would be as impossible as melodeons or lawn mowers. Such a hospital must be manned. Its personnel are soldiers first, and nurses afterward; for it is for hard service, and meant for fatigue, privation, weathers and confusion. It may be idle sometimes, and acquire Spartan luxuries, but nothing but some overwhelming misery of the sick should intrude an unaccustomed and alien attendance.

May we hope that among the lessons of the Spanish War we may count this one, that the regimental and field hospitals are not the places for the treatment of typhoid cases or broken thighs, or for the best use of trained nurses.

Meanwhile questions of medical organization for war, which have, since the days of the Civil War, been in a condition of nebulous uncertainty, will in due time come before the General Staff for careful and systematic study, and although that body has, by a curious anomaly, no medical representative on it, it is probable that this defect will in time be remedied, and that the medical officer of the future will enjoy the heretofore unknown privilege of knowing beforehand what is to be the medical organization for the next war.

(To be continued.)

Clinical Reports.

EXTENSIVE PANCREATIC NECROSIS WITH RECOVERY.

J. F. BALDWIN, M.D.
Surgeon to Grant Hospital.
COLUMBUS, OHIO.

Introduction.—At this time, when the attention of the profession is directed so earnestly to the pancreas, the report of the following case, with the lessons to be derived from it, can not fail to be of much interest.

History.—W. J. G., a practicing physician of Columbus, Ohio, aged 52, had always enjoyed good health until the latter part of August, 1903. About thirty years before he had had some symptoms which led him to suspect the presence of gallstones, but he had been entirely free from the symptoms until six or eight years ago, when he became subject to occasional brief attacks of "indigestion." In August, after eating some ice cream, he had an attack of acute indigestion, with severe pain, vomiting, etc. More or less trouble in the region of the stomach persisted after that time, with several attacks similar to the one in August. During these attacks he vomited freely, and eructated a good deal of gas. The vomited material was never characteristic. Pain and soreness were at times present, which he referred to the pit of the stomach, the pain extending into the right shoulder. There was never any jaundice.

Present Condition.—Two days ago (Dec. 2, 1903), one of these exacerbations came on, but with more than usual severity. He vomited very freely the first day, but none since yesterday. Temperature at 10 a. m., 100; pulse, 100; at 4 p. m., temperature, 100.5; pulse, 108. He has had three movements of the bowels from calomel taken last night and Pluto water this morning.

Examination.—Patient has an offensive breath and some coating of the tongue, is very tender over the entire abdomen, but most tender at the pit of the stomach, and to the right. Tenderness is so great as to render palpation and percussion entirely unsatisfactory. Some abdominal distension exists. What seems to be an indistinct tumor can be made out to the right of the median line, and just above the line of the umbilicus. Tenderness is too great for satisfactory examination.

The diagnosis of gallstones with acute cholecystitis was made, and palliative treatment advised.

Course.—December 6. Patient's condition has become very much worse in every way, and it is evident that the case is one of fulminant cholecystitis, or acute pancreatitis. The tumor previously mentioned is now more distinct, but the parts are too tender to enable its relationship to the liver to be determined. Operation was advised and promptly accepted, and the patient was at once removed to Grant Hospital for operation next morning.

Operation.—December 7. Assistant, Dr. Goodman; anesthetizer, Dr. Rice. Under the anesthetic I could determine a line of stomach tympany between the tumor and liver. This excluded the gall bladder as the site of the tumor, and left only the pancreas. Incision was made directly over the tumor. As soon as the peritoneum was opened, extensive fat necrosis was found, involving the omentum and peritoneum. The gall bladder was in easy reach, and was found to contain a number of medium-sized stones, which were removed in the usual way. No stones were present in the common duct, nor in the diverticulum of Vater. The omentum, which was unusually thick, was torn through, and the stomach lifted up, and after separating some light adhesions, the entire pancreas was explored by the hand without much difficulty. It was found considerably enlarged, the principal enlargement being in the region of the head. A large rubber tube wrapped in gauze was introduced down to the pancreas, drainage introduced into the gall bladder, which had previously been attached to the edges of the muscular incision, and the rest of the incision closed after protecting the field of operation by the introduction of washed iodoform gauze. Three of the gallstones were about the size of the end of the finger, and were very black. The rest (52 in number) were quite uniform in color and shape, being about the size of ordinary shot.

Recovery.—The patient made a somewhat slow but very satisfactory convalescence, and left the hospital, Jan. 13, 1904, with some discharge from the gall bladder and also through the sinus leading to the pancreas. January 23, patient telephoned me that he was having some trouble with the sinus, and on examining him I found the sinus plugged up with what on removal proved to be four large pieces of pancreas. February 7, he passed several other pieces, and minute bits have been passed from time to time since then, the last appearing about April 15. It is estimated that altogether from an ounce to an ounce and a half of pancreas have been thus discharged. The sinus has now practically closed.

The patient has for several weeks been steadily improving in health, and now regards himself as entirely well. At no time has there been any sugar in the urine, or fat in the stools, or other evidence of disturbed pancreatic function.

Comments.—The literature at my disposal and correspondence with Dr. Opie of Johns Hopkins Hospital, reveal no similar case. Cases are on record in which the necrotic pancreas has been discharged through the bowel, but none in which necrotic pancreatic tissue has been given exit by surgical means. The case is, therefore, of interest as being thus unique, and as showing the result of prompt intervention in a case of acute hemorrhagic pancreatitis.

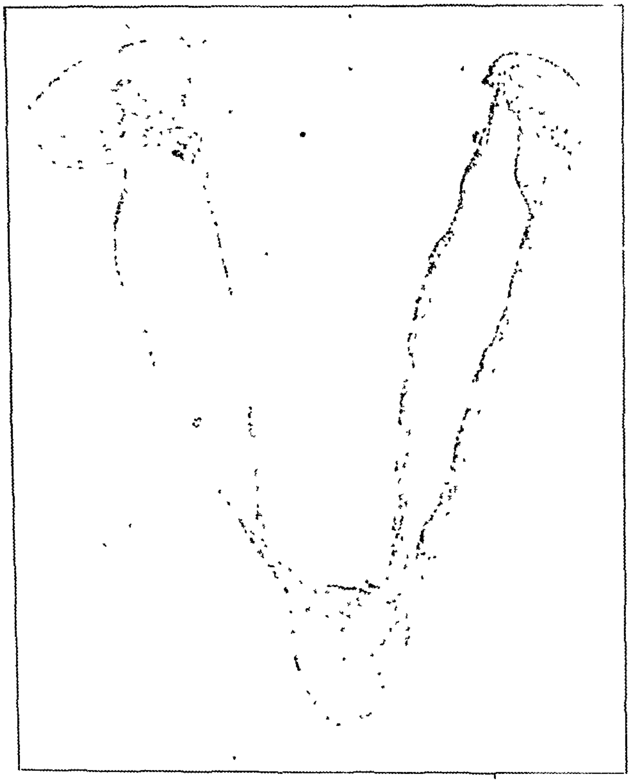
125 S. Grant Avenue.

BILATERAL DUPLICATION OF THE URETERS.

LOUIS A. LEVISON, M.D.
TOLEDO, OHIO.

History.—G. F., male, aged 65, was admitted to the county hospital Feb. 15, 1904, presenting signs and symptoms of advanced pulmonary tuberculosis. He died Feb. 25, 1904.

Autopsy.—Both lungs were tubercular. Beside this condition, there were several interesting anatomic anomalies. The transverse colon was U-shaped, nearly reaching the pelvis. The liver presented a number of deep fissures across the phrenic surface, extending in an anteroposterior direction. From the left lobe of the liver an additional long, flaplike lobe, projected toward the left. Each kidney showed pathologic as well as anatomic changes. The left kidney measured 11x5x3 cm. and showed evidences of contraction from a chronic inflammatory change. The right kidney was markedly atrophic. It measured 7x3x2 cm. and presented changes similar to the left kidney. From each kidney arose two fully developed ureters, each having a separate pelvis, but the two ureters on each side entered the bladder through a common orifice. The distance between the two ureteral orifices is considerably increased. One of the ureters passing from the right kidney is widely dilated throughout. At its beginning it is 4 cm. wide, becoming more narrow lower down, but still remaining three or four times the normal diameter of the ureter.



Bilateral duplication of ureters.

Remarks.—Judging from the number of cases of bilateral duplication of the ureters reported, the condition must be one of extreme rarity. Gould has recently found eight cases in the literature, to which he adds two. Dechtel reports one case, making in all, eleven cases previously reported. Unilateral duplication of the ureters is somewhat more common, but still of sufficient rarity to be of interest.

A SIMPLE CLASS-ROOM METHOD FOR GROWING ANAEROBIC CULTURES.

LEONARD K. HIRSHBERG, A.B., M.D.

BALTIMORE.

The difficulty experienced by all instructors in bacteriology in having each student successfully cultivate anaërobic organisms, induces me to bring this simple method before those who teach this subject to large bodies of students. The method is applicable to all anaërobes and it was first tested by our last class of fifty students, the great majority of whom thus effectively grew cultures of *B. aerogenes capsulatus* (Welch), *B. anthracis symptomatici*, *B. œdematis maligni* and others.

A stab culture of the organism is made in an ordinary non-slanted agar tube. A second agar tube is melted in a water bath and allowed to cool to 40 C. The cooled solution of agar is then impregnated with two cubic centimeters of pyrogallic acid which has been freshly prepared by adding to one part of water an equal quantity of the acid and an equal quantity of a 5 per cent. sodium hydroxid solution.

The melted pyrogallic acid-agar is then quickly poured into the tube previously inoculated and the latter is then incubated. After twenty-four hours an abundant growth will usually be seen in the lower part of the clear agar.

New Instrument.

A TENACULA SCISSORS FOR THE REMOVAL OF DEEP-SEATED PERMANENT SUTURES.

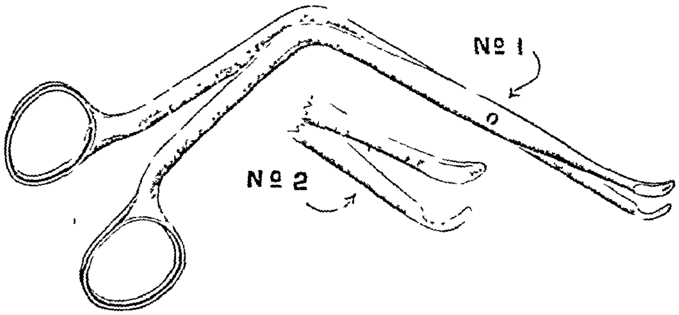
CHARLES NELSON BALLARD, B.S., M.D.

Assistant Professor of Gynecology and Clinical Gynecology, College of Physicians and Surgeons; Assistant Surgeon Marion Sims Hospital.

CHICAGO.

Surgeons who find it necessary to do work in the deeper cavities of the body wish many times to use permanent suture material, but refrain from doing so on account of the difficulty of its removal with the present instruments manufactured for this purpose.

Absorbent suture material can be used for much of this work, but often it is better to use something more fixed or splint-like to hold the parts accurately coaptated till union takes place. All absorbent material relaxes to some extent when it becomes saturated with the secretions of the tissues in which it is used. If the tissue is very firm there is a tendency for the parts to separate, owing to the stretching of the absorbent material used. As examples are vesicovaginal fistula, rectovaginal fistula, amputation of the cervix, trachelorrhaphy, or any operation in the vagina which makes it necessary to use permanent suture material such as silkworm gut. This material is difficult to remove from these positions with the forceps and scissors, or tenacula and scissors.



To use these two instruments it makes it necessary to use both hands, thus obstructing the view of the operator. The scissors are usually sharp pointed and wound the tissues near the suture.

The tenacula, if sharp, also pricks the tissues, causing more or less laceration, and a tendency to the formation of unhealthy granulation.

All of this trouble has induced me to devise an instrument which does away with the two sharp pointed instruments and replaces them with one probe-pointed tenacula scissors with a drop handle. Thus the view of the operator is not obstructed and the tissues are not cut or punctured by sharp-pointed instruments.

In the accompanying illustration No. 1 shows the instrument slightly opened and one-half size. No. 2 shows the *tenacula* and scissors point full size.

The scissors side has a curved edge made to accurately fit the curve of the tenacula side. The tenacula side also has a cutting edge.

These edges are prevented from injuring the tissues by each side being probe pointed. Nowhere is the cutting edges exposed so as to come in contact with the tissue. As soon as the stitch is picked up by the tenacula side, the handles are closed and the suture is cut with any other scissors.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

103 Dearborn Avenue . . . . Chicago, Ill.

Cable Address . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

SATURDAY, MAY 21, 1904.

THE GLORIOUS FOURTH AND THE INGLORIOUS FIFTH.

After the smoke and noise of the last celebration had died away and the returns of the annual holocaust were in, The Journal summed up the cost of life and limb as it had not been done before, and published[1] the totals with their full and dreadful significance. Since that time we have had many reasons for being glad that we did the work and presented its results, for throughout the country many earnest workers for civic betterment have availed themselves of our figures to use as argument to secure the passage of ordinances directed to the prevention of these mournful features of a day of noise and turmoil. From many states have come newspaper accounts of city councils passing bills directed against the sale of toy pistols, blank cartridges and giant crackers to minors, and quoting the figures that we published last August—406 deaths from lockjaw, 60 from other causes, and 3,983 injuries that were not fatal.

The time has now come to look forward once more to the coming Fourth, and to see if, in the light of our past experience, a complete repetition of the annual calamity can not be avoided. It is evident that a certain amount of public sentiment has been stirred up in one way and another, but whether it will assume its activity at the proper time is another question—the most general condemnation of the method of celebrating the Fourth, and the loudest calls for a change are usually heard about August 1. In Chicago last year a pathetic example of this was furnished. There have been standing on the city statutes of Chicago for many years ordinances providing penalties for the sale of pistols to minors, but their enforcement has never been anything worth mentioning. In the latter part of June, 1903, after a few premature lockjaw cases had followed blank-cartridge injuries, some desultory arrests of venders of these weapons were made, but no general effort was made to close down on this source of trouble. The small boy had not the slightest difficulty in procuring the materials for his destruction, as we easily demonstrated by experiment. But when the daily papers began to fill with reports of deaths from lockjaw a few days after the Fourth, *then,* and not until then, was any determined effort made to stop the sale of toy pistols. At that time we found that a boy in knee trousers had to go sometimes to as many as two or even three stores before he could purchase a toy pistol.

The lesson is plain. Something must be done now to awaken the police departments of our cities to their duties in this direction. Last year 64 per cent. of the total injuries and over 80 per cent. of the fatal injuries were the results of blank cartridges. Nearly all cities, it would seem, have at some time passed ordinances that control their sale, or the sale of the pistols in which they are used, but, as a rule, the ordinances have remained on the books unconsulted and non-enforced. It would not be a difficult matter to reduce this source of mortality greatly; the pistols and cartridges are sold usually by dealers in sporting goods or in "notion stores," and every policeman knows all such places on his beat. Confiscation of pistols from boys on the Fourth would also be of some service. Enforcement of the law is the chief thing that is needed. In Washington, where these matters seem to be controlled better than in ordinary municipalities, Fourth of July tetanus is extremely uncommon, although there are a fair number during the year from other causes.

It seems to us that there is a good field for the activities of local medical societies in this particular branch of preventive medicine. Passing of resolutions requesting the enforcement of such laws, if they exist, or the drafting of them where lacking, if sent from representative bodies of medical men to the proper authorities, and if published in the daily papers to create popular interest, would not fail to be of effect, either immediately or remotely. It will be found that with few exceptions the daily papers are ready and eager to take up this cause, and they furnish powerful aid. Last year much good work was done by the press.

A good suggestion for other cities is to be found in the establishment in Chicago of an incorporated association—the Chicago Amusement Association—with the purpose of improving Fourth of July celebrations. It is planned by this organization, which is supported by popular subscription, to secure enforcement of the laws, to aid in prosecution when they are violated, and particularly to do everything possible to educate the public as to the necessities of the situation.

THE SCOPE OF STATE SANATORIA.

There is a growing sentiment for the segregation and treatment of the tuberculous. We in America are in this respect far behind Europe, especially Germany, and it is encouraging to observe our own slow but beginning progress.

The Ohio State Legislature, which recently adjourned, appropriated $35,000 for the preliminary work in the creation of such an institution. Of course, "politics" played its accustomed part, and it is not yet clear that the medical profession will be permitted to have anything to say about the personnel of the creating and governing commission or about the location and scope of the institution. There is manifest a disposition to put the matter in pseudomedical hands that seek something other than the advancement of medical science or the alleviation of human suffering, though such action has not yet been taken. It is expected that the medical profession of Ohio, now well organized, will see that the embryonic institution is saved for its legitimate purpose. In these days of well-nigh universal "grafting," public eleemosynary institutions appear to be a favorite field for such enterprise. Physicians, through their organization, will now find themselves able to do much toward keeping straight the authorities of those institutions in which they are chiefly interested.

---

[1] The Journal, Aug. 29, 1903. Now procurable in pamphlet form.

The Ohio sanatorium is designed to care for three hundred cases of "incipient" tuberculosis. Its declared purpose, then, is only for the attempt at cure of the early cases. These, however, are the cases in which the outdoor treatment, whether applied at home or in favorable climate, promises the best results. A state sanatorium thus limited in scope may do a great deal of good if properly managed, but it will do nothing whatever toward stamping out the contagion from the community. The advanced cases are to be permitted to spread the infection, thus creating a constant supply of new material for the sanatorium.

As the incipient cases occur in those not yet broken in health or unable to support themselves, it would certainly seem that when the state undertakes to care for those suffering from tuberculosis, it should begin with providing a place for the segregation of those cases that are diffusing the contagion. There is yet no positive proof that the sanatorium treatment of incipient tuberculosis is measurably more effective than the open-air treatment at home when this is scientifically and thoroughly applied.

The pathologist and the therapeutist feel that the Ohio movement is greatly in danger of diversion into a false channel. The organized profession should strongly urge the commission in charge to ponder its task most seriously before finally deciding on a fixed course. The commission should have all the facts plainly set before it.

The general physician, even when practicing among the poorer classes, is able to do wonders for his tuberculous patients in the early stages through the outdoor treatment. Cases in the later stage can not be successfully cared for at home, and, in addition, as centers of infection, they are a menace to their families and to the whole community. Is it wise, then, for a state institution to enter into competition with the practicing general physician? Is it not very much better to begin by segregating the advanced cases of tuberculosis, thus aiding the practitioner by relieving him of the cases in which treatment is almost hopeless and at the same time ridding the community of the grave danger of infection?

THE ETIOLOGY OF WHOOPING COUGH.

It has long been assumed that whooping cough is an infectious disease, although the etiologic factor has not yet been positively determined. Many careful observations have shown that the disease may be communicated from one person to another, and that it may be carried in the sputum from the sick by a third person. It is also well known that one attack confers a certain degree of immunity, a second attack in the same person being only rarely observed. Investigations to determine the etiologic factor have not been wanting, but the results reported are of a very heterogeneous character. Some of the earlier investigators described a protozoön, but of late these observations have been discredited. Various cocci have also been regarded as the cause of whooping cough, but this view has also been discarded. More recently a number of small bacilli closely resembling the influenza bacillus have been described by several investigators, but there is no close agreement among the reports of the different observers.

Czaplewski and Hensel were among the first who described in detail a bacillus which closely resembles the influenza bacillus, and which they believe to be the cause of whooping cough. They found this organism in all of forty-four cases of pertussis which they examined, in five cases of bronchitis which later developed pertussis, and in a case of rhinitis which affected one of the investigators during the progress of this work. The organism is non-motile, and grows on all ordinary culture media except potato. It stains well with ordinary anilin dyes, and young cultures on artificial media retain the stain by Gram's method. The staining with the anilin dyes is not uniform, but more intense at the ends than near the middle of the bacillus, a circumstance which may easily lead to this organism being mistaken for a diplococcus. On Loeffler's blood serum it forms small, nearly colorless, transparent, sometimes grayish, colonies, which seldom acquire a diameter of more than 1 mm. About the same time that this work appeared, Koplik described a very similar organism which he found in thirteen of sixteen cases examined. In 1901 Jochmann and Krause examined the sputum of thirty-one cases of pertussis, and in twenty-five of these found a bacillus which resembles the influenza bacillus. Eighteen of these organisms were different from the others, in that they do not grow on ordinary media, but grow on media containing hemoglobin. They believe that this organism may be the cause of whooping cough, and that the one described by Czaplewski and Hensel is identical with one of their other bacilli, which grows on ordinary media, and to which they assign no special importance. Manicatide[1] recently reported a series of eighty-two cases, in sixty-seven of which he found a small bacillus resembling the bacillus of influenza. This organism is 0.5 μ long and about one-half as thick, and differs from that described by Czaplewski, in that it grows on potato and does not show the polar staining. It grows on all ordinary media, and its bouillon cultures are agglutinated by the serum from patients affected with whooping cough. Manicatide immunized two sheep and two horses against this organism, and used the immune serum in the treatment of eighty-nine cases of pertussis with favorable results. The paroxysms are said to have been less severe and less frequent after the first injection, and a number of cases were cured in one to twenty days after the beginning of the treatment.

---

[1] Zeitschr. f. Hyg., Dec. 29, 1903.

It is evident that there is a lack of uniformity in the observations thus far reported, and that more work must be done before we can speak of a specific bacillus of pertussis, as has been done by Jochmann. The mere fact that an organism is found, together with other bacteria, in the sputum of a large percentage of cases, does not prove that it is the etiologic factor of the disease. In all of these investigations streptococci were found nearly as often as the so-called bacillus of pertussis, but no one regarded them as the cause of whooping cough. In regard to the agglutination test, we know that it is not always specific, as is shown by the fact that a colon bacillus may be agglutinated by dysentery immune serum, and typhoid bacilli may be agglutinated by the serum of patients suffering from jaundice. As whooping cough is a self-limited disease, the cures reported by Manicatide can not be accepted as proof that the organism which he injected into the immunized animals is the cause of whooping cough. More extended observations are necessary, and until this work has been confirmed by others, the question of the etiology of whooping cough must be regarded as unsettled.

HUMAN AND EXPERIMENTAL LOBAR PNEUMONIA.

In view of the frequence of lobar pneumonia in man it may seem remarkable that all experimenters have found it so difficult to produce the same disease in animals. A vast amount of work has been done in this direction, for the unsolved puzzle of the manner of invasion of the lung by the pneumococcus has been a strong incentive, and it is evident that if we can find a method of producing lobar pneumonia with constancy in animals, we have an important aid in learning the truth of the matter, not to mention a good starting point for studies in therapy. The usual results obtained in experiments of this kind have either been the production of a rapidly fatal septicemia without any considerable lung lesions, or else, at the best, foci of bronchopneumonic type in the lungs. A true diffuse, exudative lobar pneumonia seldom develops, no matter what the means employed, and when it does appear it is only as an exceptional result of methods that are not ordinarily successful.

Wadsworth[1] has made an exhaustive study of the results of other observers, and applied the facts so obtained to a series of new experiments that were exceptionally successful, and that seem to indicate many important things concerning certain of the features of lobar pneumonia. It would seem that man is relatively insusceptible to the pneumococcus during his adult years, as compared with the laboratory animals, and that it is this lack of susceptibility that determines the limitation of the infection to the lung in the peculiar form of pneumonia. It is now known to bacteriologists that lobar pneumonia as it occurs in man is practically always due solely to the pneumococcus, although other organisms may happen to be present; to this extent the pneumococcus is the specific cause of the disease. On the other hand, the pneumococcus is not a specific organism, in that when it infects the lung it does not necessarily produce lobar pneumonia—it may cause bronchopneumonia, or pleurisy, or septicemia, or even a simple bronchitis. When pure cultures of the pneumococcus are introduced into the lungs of laboratory animals, there usually result relatively slight lung lesions, but a rapidly fatal septicemia. When the lung lesions are more prominent they are generally of bronchopneumonic form, and very rarely lobar. This seems to be due to the relatively high susceptibility of the animals to the pneumococcus, so that it does not produce a localized process in the lungs, but spreads rapidly throughout the body. By a series of studies Wadsworth found that it was possible to produce lobar pneumonia by using attenuated organisms injected intratracheally, but that it was necessary carefully to balance the susceptibility of the animal and the virulence of the germ. By previously immunizing the animals to the pneumococcus to a certain degree, so that they had sufficient resistance to prevent general infection, it became possible to produce typical lobar pneumonia much more constantly, for in these animals virulent organisms may remain in the lungs long enough to produce diffuse exudative pneumonitis, before causing death. It thus becomes possible to regulate conditions so that lobar pneumonia can be produced with sufficient frequence to permit of valuable studies being made in the therapy of the disease, certainly an important step.

A marked resemblance can also be seen between these results in experimental animals and the results of pneumococcus infection in man. Healthy adults are too resistant to become infected, except, perhaps, rarely with an extraordinarily virulent strain of the germ. The occurrence of epidemics may be explained in this way, the bacteria becoming extremely virulent for man by growing for several generations in a series of human hosts, for the pneumococcus is particularly capable of exalting its virulence by passing through the same sort of host repeatedly. But when the adult is rendered more susceptible by exposure or disease, pneumococci of ordinary virulence may cause lobar pneumonia. On the other hand, children, the senile and the marantic, having very little resistance, are in a condition more like that of the laboratory animal, and, therefore, similarly are much more likely to have the lobular form of pneumonia with an early fatal septicemia. So in man, as in rabbits, the development of diffuse lobar pneumonia requires a certain relation between the resistance of the host and the virulence of the bacteria; the chief difference is that man, normally having high resistance, is more frequently in the proper condition for this occurrence than is the rabbit, in which the resistance must be raised, for it is easier to reduce than to increase the powers of defense.

CRYOSCOPY AS A GUIDE TO THE ABSORPTION OF CHRONIC SEROUS EFFUSIONS.

Recent observation tends to attribute increasing importance to chemical and physical influences in connection with various physiologic activities, although at the same time not ignoring the part played by cellular function under such circumstances. Thus it is recognized that the absorption of serous effusions is largely governed by factors influencing osmosis and diffusion. In accordance with the character of the exudate present, an interchange of fluid, salts and albumin will take place between the blood and the serous effusion, the tendency being constantly toward equalization.

To determine whether such physical laws are applicable practically to physiologic and pathologic conditions, Dr. Ladislaus v. Ketly and Dr. Arpad v. Torday[1] made a comparative study of the molecular concentration of the blood and of the fluid obtained in fifteen cases of pleural and peritoneal effusion by means of observations on the reduction in the freezing point. As a result the conclusion was reached that the absorption of chronic pleural exudates can be expected to take place in those cases in which the reduction in the freezing point of the serum obtained by puncture is lower than that of the blood serum, or, at least, is nearly the same. This statement is applicable only to such cases as are unattended with fever or other symptoms indicative of inflammation of the layers of the pleura, for so long as such a condition exists further production of exudate is to be expected. Also in cases of pleural effusion due to nephritis the reduction in the freezing point of the blood serum should be determined. Under such circumstances an opinion can be formed from cryoscopic observation only when the secretory activity of the kidneys is adequate. The absorption of peritoneal exudates of tuberculous origin is dependent on the same factors as influence the absorption of pleural exudates. In cases of peritoneal transudate a conclusion can be based on the results of cryoscopic examination only when the accumulation of fluid is not prevented by mechanical hindrances. A decisive factor in cases of peritoneal and pleural transudate resides also in the cardiac activity. In addition to the results of cryoscopic investigation the condition of the heart must further be taken into account. As a sharp delimitation between an exudate and a transudate can not be made from the determination of the specific gravity and the amount of albumin present, an attempt was made to utilize the cryoscopic method for this purpose, but the results show that the procedure is not capable of distinguishing the one from the other.

The suggestion has been made that the absorption of old exudate is favored by increase in the osmotic pressure, and to this end a proteid diet is recommended, as the complex proteid molecule is decomposed in the body into simple molecules, with the result that the osmotic pressure of the blood is increased. Similar effects are ascribed to drinking-cures with sodium-chlorid water, sweating-cures and mud-baths. There is no doubt that the last method favors and accelerates the absorption of chronic pleural exudates, as has been abundantly demonstrated clinically. The same procedures are likewise often invoked to aid the absorption of exudates of other character. Some doubt prevails, however, as to the utility of drinking-cures in this connection. The results obtained from a determination of the osmotic pressure were used as an indication for or against puncture, this being practiced when absorption of the fluid was not to be expected, and conversely.

CLUB PRACTICE.

According to the *Northwestern Lancet,* Minnesota is seriously ridden with lodge practice. While other states are perhaps as badly afflicted, if not more so, lodge practice has become such an evil in that state that it is exciting more than usual attention. The last number of the *St. Paul Medical Journal* contains a number of replies to inquiries from prominent physicians giving their views on the subject. The question is to be brought before the state house of delegates at its session next month on an appeal from a county medical society from the decision of a district councilor, and we trust it will receive thorough consideration. It appears that at least one-sixth of the population of the city of St. Cloud are beneficiaries of lodge practice on the payment of $1.00 (or $2.00 if the whole family is included) per annum.

The opinion of The Journal in regard to this question of contract practice has been expressed on numerous occasions, and we have printed from time to time various items showing the extent to which it may develop, if unchecked, as illustrated by what has developed in countries like Great Britain and Germany. How a self-respecting man can take up the responsibility of the life and health of individuals for $1.00 or $2.00 per year is rather beyond our calculation and the disadvantages, not only to himself in the long run, but to his professional brethren, need no extensive argument to be demonstrated. With the question of corporation physicians the case is somewhat different, for, if the salary is adequate and the business confined to accidents and emergencies, they are not necessarily objectionable. However, any sweating of the profession by a corporation is just as bad in its way as by the benefit societies and likewise should be condemned.

---

[1] Deutsches Archiv f. klin. Med., vol. lxxix, Nos. 5 6, p. 563.

In its editorial comments on the subject the *St. Paul Medical Journal* makes a proposition which seems to us altogether uncalled for. It suggests that the present physicians holding contracts, and those wishing to join with them, form an organization to regulate contract practice. To leave the matter entirely in the hands of the offenders would be reform with a vengeance and would not go far toward mending matters. The only proper thing to do is to insist on what our German brethren are insisting, namely, that individual physicians make no contracts with benefit societies, but allow the members of these clubs to consult any physician, paying the regular fees. They would then be what they pretend to be, insurance companies against sickness and probably could, if well managed, conduct such business profitably. The question is simply an actuarial one. The club doctor's experience in the long run, when he is no longer a club doctor, will teach him the disadvantage of this kind of practice. Poor pay means poor service all the world over and the clubs will find that out, but in the meantime the injury that they can do to the medical profession is almost incalculable. Of this we have evidence enough from experience abroad. Matters regulate themselves in time; nothing is fully settled until it is settled right, but if unassisted by active human effort, the mills of the gods grind slowly.

We repeat: It is time that the organized profession in its delegated bodies take up this question and settle it. It is not necessary to get up a special organization to oppose this club practice as our German confrères have had to do; we are already organized and ready. The question to be decided is: Shall it be consistent with membership in our organization for a member to enter into a contract with a lay organization existing largely or solely for the purpose of sweating the medical profession?

RUSH MONUMENT DEDICATION.

President Roosevelt has consented to accept the Rush monument on behalf of the nation as a gift from the American Medical Association. The ceremony will take place at Washington Saturday afternoon, June 11, at 4 o'clock. It will consist of an introductory address by the President of the American Medical Association; an oration on Benjamin Rush by Dr. J. C. Wilson, Philadelphia, and then the address of the President of the United States accepting the gift.

THE PRACTICAL OBJECT OF ORGANIZATION.

When discussing medical organization there is a point not yet clearly understood by all that should not be overlooked. The chief purpose of the reorganization of medical societies that has been progressing since 1900, is not simply the scientific advancement of medicine. This was well accomplished in the main by the older form of medical society independent of affiliation with other bodies. It was the disorganized state of the profession when called on to face political attack, to accomplish legislative reform, to protect itself from malpractice injustice, to speak with some show of authority on medical questions having a public or semipublic bearing, or to act for the whole medical profession, that necessitated a closer union for the promotion of the material welfare. It is true that the same object might have been attained by organizing a national legislative league, a national medical-defense union, a national physicians' benevolent association, and a dozen other allied independent organizations. But in this way effort would have been scattered and energy dissipated. Clearly it was wise to utilize the existing dissociated societies without in the least interfering with the effectiveness of their scientific work. The perfection and accurate dissemination of medical knowledge certainly is one of the chiefest and most altruistic objects of medical-society fellowship, and the accomplishments in this direction of American medical societies have been second to none. The purpose of the recent wave of reorganization has been to bring this work into new territory—ultimately every county in the Union—and at the same time to unite all eligible physicians in one organization that can speak with authority for the whole profession whenever the welfare of the community demands it or its own interests are threatened.

PASTEURIZED MILK.

What is pasteurized milk? Strictly speaking, this term should apply to a milk which has been heated to a temperature sufficient to kill pathogenic micro-organisms but not sufficient to destroy the enzymes or to materially alter the albumins in the milk. Unfortunately, there is a lack of unanimity among the authorities as to just what temperature is needed to effect this. Russell, Theobald Smith and Hesse have found that 60 degrees C. for fifteen to twenty minutes is sufficient to destroy the bacillus of tuberculosis. Kobrak says 65 degrees; Forster the same. Holt advises 65 for twenty to thirty minutes, while Rotch apparently always employs 75, although it is generally understood that anything over 69 destroys the ferments in the milk and materially alters albumin and lecithin. The question is an important one. Recent researches, notably those of Rabinovitch,[1] show that tubercle bacilli are frequently present in the milk of cows who show no outward signs of tuberculosis, and it is, therefore, of the greatest importance to know just what degree of heat is necessary to destroy these organisms. The statements of Hesse and Theobald Smith that a temperature of 60 degrees was sufficient, have been questioned by Gerber and Wieske, and more recently by Rullman,[2] who mixed fresh tuberculous sputum with milk and then subjected it to various temperatures, after which he used it for intraperitoneal injection of guinea-pigs. The milk, which was heated to 60 degrees C. for twenty to thirty minutes, caused tuberculosis in guinea-pigs in every instance. The same was true of milk heated to 65 for the same length of time. Of six animals inoculated with tuberculous milk which had been heated to 65 for an hour, three gave negative and three positive results. Only a temperature of 68 continued for a full hour gave negative results in all the animals injected. Rullman concludes that a temperature of 68 C. maintained for an hour, with constant agitation, is necessary to destroy the bacillus of tuberculosis, while, if the milk is then rapidly cooled, the flavor will be unchanged, the enzymes not destroyed and there will be only a slight alteration of the albumin and lecithin.

[2] Münch. med. Woch., March 22, 1904, p. 508.

THE APPLICATION OF THE GRAPHIC METHOD TO DIAGNOSIS.

Since the days of the great Piorry physicians have used the graphic method in locating accurately the outlines of certain organs in diseased conditions. Particularly in cardiac and pulmonary affections areas of dullness or adventitious sounds are mapped out on the patient's skin by means of colored pencils. In a recent address Lannelongue[1] has advocated a more extensive application of the graphic method. He claims that particularly in diseases of the joints, and to a less extent in the abdomen, the method may be of considerable value. In the case of suspected joint lesions, especially when these are in an early stage, he maps out with colored pencils the bony prominences and lines of articulation on the two sides, the two joints being held, of course, in exactly similar positions. By this means, according to Lannelongue, slight aberrations from normal which might be overlooked or misjudged are rendered much more apparent than mere palpation would make them. In the abdomen, by means of a pentagon, the angles of which occur at the pubes, the anterior superior spines, and the rib margins at the mammary lines, the author shows the situation of the various parts of the intestine and the attachment of the mesentery. The method appeals to us as one which may be of value in some cases, especially to those physicians in whom the sight is more developed than the touch.

BERI-BERI.

The special form of endemic neuritis, known as beriberi, is a widely disseminated disease in many tropical countries. Occasional epidemics also appear elsewhere, e. g., among Newfoundland fishermen and in British prisons. The disease may also be brought north in crews returning from the tropics. Great diversity and uncertainty of opinion prevail as to the real cause of this disease. Many regard it as a form of food poisoning; others as the result of fish diet; others, again, as a true infectious disease. Hamilton Wright, who has had excellent opportunity to study beri-beri in the Malay states, adopts the last view, for the reason that in a prison in which this disease had been endemic for years, he observed the development of the disease in prisoners in certain cells and also in monkeys placed within the same cells and fed properly. It seemed as if the cause was resident in the cells and, if we are correctly informed, the disease was banished from this prison by improving the sanitary conditions. Hence Wright holds that beri-beri is not food poisoning, and that it is independent of the nature of the food as such, although the food may convey the special cause, which thrives in dark, unventilated sunless places. Now, in acute cases, there is congestion and hemorrhage of the mucous membrane about the pylorus and in the duodenum, and Wright regards this as the point of localization of the unknown cause, while the nervous lesions and symptoms are the result of intoxication with substances having special affinity for the nerve cells. Depending on the intensity of this intoxication and the part of the central nervous system most affected, will be the character and the outcome of the attack, as well as the nature of the nervous lesions. In acute pernicious cases, in which death may result from involvement of vital centers, the nerve cells show extensive degenerative changes; in more chronic cases the peripheral nerves show secondary processes, dependent, of course, on the earlier lesions of the neurocytes. According to Wright's hypothesis, beriberi is an infectious disease, the cause of which remains localized in the gastroduodenal walls, where it elaborates a powerful neurotoxin. This seems a promising working hypothesis for further studies with the view of demonstrating the organism. Certainly the development of beri-beri in the imprisoned monkeys[1] is very suggestive, although the length of time they remained in the cells before the symptoms appeared—from one to two and one-half months—seems to indicate that it concerns a disease, which, if infectious, perhaps has a long incubation period.

PSYCHIC DIET.

"Yellow literature" is a nuisance—not to say a curse—especially to the young. It is generally supposed that we suffer more from this than other countries, owing to the freedom of the press and the lack of any censorship whatever excepting that which may be given by certain local and United States laws for the grosser objectionable productions. But this is perhaps a question. We read not long since of the son of a Japanese prince who, instigated by dime-novel literature, started out to become a pirate in the West Indies. If the evil is thus advanced in far Japan, what shall we say of the older Western civilizations? It is not only, however, the "penny-dreadfuls," as the English call them—the blood-and-thunder dime novel—that is damaging. There is a large class of readable literature of which it would be well if young people could forego all acquaintance. A German physician, Dr. Laquer[2] of Wiesbaden, has recently brought out this point. He accepts as a threefold cause of psychic instability, abnormally increased self-analysis, fear and lack of will power, and the reading of exciting literature. He advises that during school life pupils avoid theaters and concerts, for music is also considered a danger. It is a negation of ideation (Gedankens) in art. We have been so long accustomed to think of music as a meritorious indulgence that this opinion seems a little extreme, but he has the backing

eminence, who have long since pointed
ultivating the musical faculty in young
s a bad effect on the emotional develop-
kind of mental diet he prescribes consists
the reading of books of travel, histories and
es, particularly of men of action, and of hu-
oks, which he recommends as specially valu-
He calls attention to the comparative paucity of
n humorous literature, but gives a list of authors
he recommends. The foreign ones consist almost
y of English writers, such as Dickens, Jerome,
ipling, and our own Mark Twain. The books he has
ers might object to some of them. Cynical and
lected are fairly representative of the best class, though
atirical humor, we believe, should be avoided as cultivating a bad mental habit, even in the young. The reading of the young should be supervised, and the theme frequently changed and the habit of concentration cultivated by writing abstracts of books read. The subject is not a new one, but one that is always worthy of consideration. We have an immense amount of literary dissipation going on, even among school children, as well as among those who are not children, some of it of the most harmful kind. Greater care should be exercised in public libraries and by parents in the selection of reading matter for children at the age when the basis of future habits is likely to be established.

THE HOSPITAL MAINTENANCE PROBLEM.

A few weeks ago, *Charities*, a New York publication devoted to the subject implied by its title, called attention to the great excess of annual expense over receipts of most of the New York hospitals as well as to their overcrowded and generally overtaxed condition. These conditions combined make the problem of hospital accommodation, especially for the poor and not well-to-do, a very serious matter. If the hospitals can not receive the support that they need, they can not care for charity cases to the full extent of the demands and must curtail their operations; in fact, several hospitals have already closed certain portions of their wards and others are proposing to do so. This is not confined to the general hospitals alone; special hospitals are also in the same predicament. The evils are obvious, but the remedy is not clear. In this country the hospitals are supported in part by public funds, in part by endowment, but very largely by voluntary contributions of the charitably minded and the question has been raised whether there should not be a larger diversion of public funds to this purpose than has been heretofore the case. There are objections to this, especially in the large municipalities. Public support implies public control, and public control is political control. We know what it may be. Our public city institutions have had too much of a reputation of being mismanaged and it is in them that the abuses are most frequently charged. Moreover, it is feared that with the appropriation of public funds, the private contributions would rapidly fall off to an extent which would overbalance the account. At present hospitals are popular institutions and are being more and more resorted to by all classes. Most of our charitable institutions are largely imposed on and receive and treat gratuitously or with slight remuneration a large class of people who are able to make much better returns. This is especially the case with large public hospitals. Much, therefore, can be done by more stringent control of admission. We know what dispensary abuse may be, and hospital abuse may be something more or less remotely approaching if not paralleling it. Another point may be considered: It is very possible that our hospitals are not managed and controlled with the economy that should be the rule. We do not mean a false economy or scrimpingness, but a rational economy. In our large cities the restrictions of space require hospitals to be expensive buildings, and this usually adds to the cost of maintenance. One thing is certain: There will have to be a regulation of the charities if they are to be successfully conducted from a financial point of view. This will require probably not only increased giving, but reform in the method and distribution of the gifts. The problem is before us and is one of the more important ones of the present day.

Medical News.

CALIFORNIA.

Personal.—Dr. and Mrs. Arthur H. Mays, Sausalito have started for Europe.——Dr. George F. Brackett, San Francisco, has resigned as chief surgeon of the Emergency Hospital Service.

New Hospital for Stockton.—Mr. and Mrs. James H. Hough have offered to build and equip a receiving hospital for Stockton and San Joaquim County, provided that the city and county shall maintain the institution thereafter.

Maternity Hospital Opened.—The maternity wing of the Pasadena Hospital, erected at a cost of $12,000 by the liberality of Mrs. Robert J. Burdette, and to be known as the Clara Baker Burdette Maternity Wing, was formally dedicated, May 2.

German Hospital Plans Approved.—Plans for the New German Hospital, San Francisco, were approved by the German Benevolent Society, April 29, and $400,000 was voted to defray the expense of construction. The buildings will be thoroughly fire-proof and will be six stories in height.

Spiritual Healer Acquitted.—Although it was shown that G. W. Winchfield, a "spiritual healer" of Oakland, had traveled for 30 years with itinerant medicine shows, and that he had received a fee of $500 from one individual, a jury, on April 28, found him not guilty of practicing medicine without a license.

State Health Commission Organized.—At a meeting of the federal, state and local health authorities in San Francisco, April 30, an organization was effected, to be known as the "Public Health Commission of California," and the following officers were elected: Dr. Rupert Blue, U. S. M.-H. and P. H. Service, president; Drs. Martin Regensburger, and James W. Ward, vice-presidents, and deputy health officer Louis Levy, secretary, all of San Francisco.

DISTRICT OF COLUMBIA.

College Merger.—The Medical Department of the National University, Washington, merged with the Medical Department of Columbian University, Washington, after the close of the 1902-1903 session.

Howard Medical School Commencement.—A class of 60, of whom 7 were women, received diplomas, May 11, from the Howard University Medical School, Washington. Rev. John Gordon, D.D., conferred the degrees and Dr. Robert Reyburn delivered the doctorate address.

To Remove Stray Cats.—The commissioners of the district are seriously considering the advisability of removing from the district all strange and roving cats because of the allegation of their being somewhat responsible for the spread of contagious diseases and also because they are an annoyance to the public.

Health of the District.—The report of the health officer for the past week shows the total number of deaths to have been

117, of which 70 were white and 47 colored; the total number of births was 102, of which 67 were white and 35 colored. At the close of the week there were 9 cases of diphtheria, 27 of scarlet fever, 49 of typhoid fever and 3 of smallpox under treatment.

GEORGIA.

Personal.—Dr. Walter A. Norton has been appointed city physician of Savannah, vice Dr. Elton S. Osborne, elected physician of Chatham County.——Dr. James B. Morgan has been elected president of the Augusta Board of Health; Dr. John M. Caldwell, secretary, and Dr. W. Harry Goodrich, coroner's physician.

State Association Meeting.—The Medical Association of Georgia held its fifty-fifth annual meeting in Macon, April 20, 21 and 22. Dr. J. N. McCormack of Kentucky, addressed the association on the subject of reorganization, and the question was referred to a committee, which reported favorably, but the report was tabled on a constitutional question. The following officers were elected: President, Dr. W. Perrin Nicolson, Atlanta; vice-presidents, Drs. Mollie A. Clark, Macon, and W. Zellars Holliday, Augusta; censor, Dr. Theodore E. Oertel, Augusta, and delegate to the American Medical Association, Dr. James B. Morgan, Augusta. The next meeting will be held in Atlanta.

ILLINOIS.

Chicago.

Smallpox on the Increase.—During last week seven cases of smallpox in six localities were discovered, and the patients sent to the isolation hospital.

Deaths of the Week.—There were 531 deaths during the week ended May 14. Of these 122, or nearly 23 per cent., were due to pneumonia; 60 to tuberculosis; 40 each from Bright's disease and violence, and 37 from heart diseases.

Consulting Physicians for School Teachers.—In addition to the regular staff of examiners, Dr. E. C. Dudley has named the following consulting staff to pass on doubtful cases: Drs. Robert H. Babcock and Charles L. Mix, heart and lungs, and Drs. Albert B. Hale and Frank Allport, eye, ear, nose and throat.

Pneumonia and Tuberculosis.—Since Nov. 1, 1903, there have been reported 3,565 deaths from pneumonia and 1,696 from consumption in this city. In New York City during the same period, the figures are 9,460 and 4,878 respectively. Pneumonia and consumption are responsible for one-third the total deaths from all causes in the two cities within the last six months and of the two pneumonia has been twice as destructive of human life as consumption.

Reduction in Death-Rate.—Another reduction in the death rate is noted for the week ended May 14. There were 101 fewer deaths reported than during the corresponding week of last year, a decrease of 18 per cent. The decrease is entirely among those under five years of age and is due to the marvellous infrequency of the contagious diseases of childhood. During the first two weeks of the month there were only 22 deaths reported from diphtheria, measles, scarlet fever and whooping cough, as compared with a total of 85 from the same diseases during the corresponding period of 1903.

INDIANA.

Personal.—Dr. George G. Graessle has been elected mayor of Seymour.——Dr. Bruce Easley, New Albany, has returned after a year in Europe.

Commencement.—The commencement exercises of the Fort Wayne College of Medicine were held April 20. During the summer the college building is to be remodeled.

Practiced Without License, Fined.—Dr. F. H. Bloomer of Lagro, was fined $25 and costs, May 7, for practicing medicine without a license. He claimed to be ignorant of the existence of a law requiring physicians to be licensed.

Smallpox.—There were reported in April 260 cases, in 29 counties, with 6 deaths. In the same month last year there were 590 cases, in 56 counties and 21 deaths. The disease assumed decided epidemic proportions in Clay County, where 56 cases occurred; in Grant County, 24 cases; in Vigo County, 45 cases, 2 deaths, and in Warrich County, 24 cases.

Improved April Health.—There was an improvement in the health of the state in April, as compared with March, but not in comparison with the same month last year. For three consecutive months measles has been the most prevalent disease. Pneumonia, which was second in prevalence in March, was fourth in April. The order of prevalence was: measles, rheumatism, bronchitis, pneumonia, tonsillitis, influenza, typhoid fever and diarrhea. Typhoid fever was also more prevalent than usual and more fatal.

April Mortality.—The total deaths for the month numbered 3,322, an annual rate of 15.2 per 1,000. In the preceding month the rate was 18.1 per 1,000, and in the corresponding month last year, 12.7 per 1,000. The increase over April of last year lies almost entirely in the increase of typhoid, influenza and pneumonia. Some important causes of death were: Tuberculosis, 385; typhoid fever, 56; diphtheria, 30; scarlet fever, 21; measles, 40; whooping cough, 14; pneumonia, 557; influenza, 72; cancer, 89; violence, 134, and smallpox, 6.

MARYLAND.

Will Have Sewer System.—The people of Havre-de-Grace have voted $20,000 to establish a sewer system.

Staff Appointments.—Among the appointments made by the governor on his staff are: Dr. John M. T. Finney, Baltimore, surgeon general; Dr. J. Charles Macgill, Catonsville, and Dr. Richard S. Hill, Upper Marlboro, aides, with rank of colonel.

Personal.—Dr. Thomas B. Horton, Curtis Bay, South Baltimore, has been appointed police surgeon, coroner and health physician of the fifth district, Anne Arundel County.——Dr. Elijah Williams, Armiger, Anne Arundel County, is spending several weeks in the pinelands of North Carolina.——Dr. William D. Straughn, Snow Hill, was operated on for appendicitis at the Salisbury Hospital last week.

Baltimore.

Hydrophobia.—Seven persons bitten by rabid dogs were admitted to the Pasteur institute of the City Hospital, May 9.

University Alumni Meet.—The annual meeting and banquet of the Alumni Association of the University of Maryland Medical Department, took place May 11. Dr. Eugene F. Cordell delivered the address on "Universities."

Examinations.—The U. S. Civil Service Commission will hold an examination in Baltimore, June 15, to fill vacancies as laboratory aids in physiology and pathology in the Department of Agriculture. Either sex is eligible, and the salary is $720 a year.

School Children vs. Mosquitoes.—Dr. Leonard K. Hirshberg has urged on the school board that the pupils of the public schools be utilized in the extermination of mosquitoes by being armed with sprinkling cans containing kerosene, as has been done successfully in New Orleans and Texas.

Staff Appointments.—Dr. Eugene H. Hayward has been reappointed pathologist at St. Joseph's Hospital for the ensuing year. The resident staff is as follows: Drs. H. C. Coburn, Jr., Walton H. Hopkins, J. M. Lynch, C. T. Rolls, and James J. Boucher. The dispensary staff includes Drs. E. L. Crutchfield, F. E. Brown, John S. Fischer and Thomas J. O'Donnell.

Medical School Commencement.—The University of Maryland School of Medicine graduated a class of 96 May 12. Hon. Edwin Warfield, governor of Maryland, delivered the address. Dr. Jesse Oliver Purvis won the gold medal, the highest distinction, and the following received honorable mention: Drs. Taylor Lewis, William J. Steward, J. J. Cleckley, and Abdallah Ezzat of Egypt. The following appointments have been announced: assistant resident physicians, University Hospital —Drs. Charles Bagley, Jr. and William N. Gassaway; resident surgeons—Drs. F. G. Wright, Alvin B. Lennan, and W. D. Scott, Jr.; assistant resident gynecologists—Drs. Hugh W. Brent and John L. Nicholson; resident pathologist—Dr. E. B. Quillin; resident physicians, maternity Hospital—Drs. Benjamin J. Bond, and Herbert E. Zepp; assistant resident physicians, Bayview Asylum—Drs. Edgar G. Davis and Joseph Coleman. ——A laboratory of original research has been instituted under the "Charles Frick Research Fund," and will be conducted during the ensuing year under the direction of Prof. José L. Hirsh, of the department of pathology.

MASSACHUSETTS.

Boston.

A Wise Appointment.—Dr. Thomas B. Shea, recently appointed health commissioner of Boston has been chief medical inspector of the department for seven years. His appointment is, therefore, in the nature of a promotion. He has been connected with the work since 1888, and is considered one of the best experts in the state on smallpox and infectious diseases.

Hospital Rebuilding.—Work has begun on the rebuilding of the Boston Emergency Hospital, a new five-story structure will replace the old building, and the work will be completed

September 1. There will be 20 private rooms and two wards to accommodate 30 patients each. Women physicians will be admitted on the same basis of practice as men. The whole will remain under the supervision of Dr. George W. Galvin. Fifty thousand patients, it is claimed, were treated here last year.

Mortality and Morbidity.—For the six weeks ended May 14 there were 1,371 deaths in Boston, an increase of 50 over the same period last year, equivalent to an annual death-rate of 19.76; 316 cases of diphtheria were reported, with 24 deaths; 89 of scarlet fever, with 2 deaths; 54 of typhoid fever, with 7 deaths; 1,094 of measles, with 16 deaths; 258 of tuberculosis, and 176 deaths. No smallpox was reported. There were 212 deaths from pneumonia; 2 from whooping cough; 146 from heart disease, 34 from bronchitis, and 23 from marasmus.

MICHIGAN.

Physician's House Burned.—In the fire at Republic, May 4, which destroyed the greater part of the business district of the town, the house of Dr. Elmer E. Lamb was burned.

The Most Dangerous Communicable Diseases.—Meningitis was reported during April at 9 places, whooping cough at 20 places. diphtheria at 61 places, typhoid fever at 76 places, pneumonia at 115 places, scarlet fever at 128 places, smallpox at 151 places, measles at 171 places, and consumption at 260 places.

Commencements.—The thirty-sixth annual commencement exercises of the Detroit College of Medicine were held May 5. Dr. Ernest L. Shurly conferred the degrees and addresses were delivered by Drs. Preston M. Hickey and Henry W. Headley. ——Michigan College of Medicine and Surgery, Detroit prefaced its sixteenth annual commencement, May 3, with a clinical week for the benefit of the alumni. Dr. Daniel B. Cornell, Saginaw, delivered the doctorate address, and degrees were conferred on a class of 28.

April Mortality of Michigan.—The total number of deaths for the month of April was 3,212, or 194 less than the number registered for the preceding month. The death rate was 15.7 per 1,000, as compared with a rate of 16.0 for March. Death by causes: tuberculosis of lungs, 272; typhoid fever, 81; diphtheria, 47; scarlet fever, 25; measles, 27; whooping cough, 15: pneumonia, 302; influenza, 104; cancer, 145, and accidents and violence, 184. There was a marked rise in the number of deaths from typhoid fever, and a decrease in the number reported from pneumonia and influenza, as compared with the preceding month. No deaths from smallpox were reported for April.

Comparative Morbidity.—For April, compared with the preceding month, measles, smallpox, intermittent fever, inflammation of the bowels, remittent fever, dysentery and cholera infantum were more prevalent; and influenza, pneumonia, pleuritis, cancer, erysipelas, diphtheria, inflammation of brain, whooping cough, meningitis, membranous croup, and puerperal fever were less prevalent. For the same month, compared with the average for April in the last ten years, smallpox, typhoid fever and diphtheria were more than usually prevalent and influenza, pneumonia, pleuritis, intermittent fever, erysipelas, remittent fever, cholera morbus, inflammation of brain, whooping cough, meningitis, membranous croup and puerperal fever were less than usually prevalent. Reports from all sources show meningitis reported at 1 place less; whooping cough at 2 places less; diphtheria at 20 places less; typhoid fever at 6 places less; pneumonia at 51 places less; scarlet fever at 34 places less; smallpox at 13 places more; measles at 10 places more, and consumption at 22 places more, in the month of April, 1904, than in the preceding month. The lessened reported prevalence of pneumonia in Michigan in April was remarkable. It is possible that some of the lessened prevalence may be due to the ten thousand leaflets on the restriction of pneumonia distributed by the State Board of Health since January, 1904.

NEW JERSEY.

Bequests.—By the will of the late David H. Chambers, the Camden Home for Friendless Children will receive $2,000, and the Camden City Dispensary $1,000.

Presentation of Bust.—At the May 3 meeting of the Camden City Medical Society, Dr. Onan B. Gross, on behalf of friends of the late Dr. James M. Ridge, presented a bust of Dr. Ridge to the society.

Sea Side Hospital.—Under the auspices of the Jewish Maternity Association, the Jewish Sea Side Home will soon be opened at Ventnor for the summer. The home was previously conducted at Atlantic City. Last summer 326 patients were treated.

Meningitis and Smallpox.—Several cases of spotted fever have developed in Mount Holly, with one death. The presence of the disease in this locality indicates its spread, as it first appeared in Bordentown and Trenton.——Five cases of smallpox have developed in one family in Deptford.

NEW YORK.

Personal.—Dr. Willard P. Spratling, superintendent of Craig Colony for Epileptics, Sonyea, has been appointed superintendent of Bellevue and Allied Hospitals to succeed Dr. William Mabon, recently appointed president of the State Commission in Lunacy.——Dr. Roswell Park, Buffalo, arrived from Europe, May 8.

Commencements.—The seventy-third annual commencement exercises of the Albany Medical College were held May 3. A class of 41 was graduated. The doctorate address was delivered by President Henry Hopkins of Williams College, and Chancellor Andrew Van Vranken Raymond of Union University presented the diplomas.——The annual commencement exercises of the medical department of the University of Buffalo were held May 3. The Alumni Association held its annual meeting on the same day, which was followed by the annual dinner at the Hotel Iroquois.

New York City.

Personal.—Dr. David Bovaird, Jr., has sailed for Europe.——Dr. William B. Pritchard has been appointed visiting neurologist to the City Hospital.

Bellevue Physician Contracts Tubercular Meningitis.—Dr. Joseph F. McCarthy, a visiting physician to Bellevue Hospital, is critically ill at that institution with tubercular meningitis, which it is supposed he contracted from a child there.

Consumption Among Street Cleaners.—The medical examiners of the street cleaning department have been ordered to make a physical examination of the sweepers and drivers employed by the city, because a large number of men who have asked for sick leave lately were found to be suffering from tuberculosis. The street commissioner hopes to find some disinfectant which can be used in street cleaning.

Large Gifts to Charity.—Solomon Loeb, who died last December, has bequeathed $107,500 to charity. Among the institutions who were recipients of bequests are the following: Montefiore Home, $10,000; Mount Sinai Hospital, $10,000; Hebrew Orphan Asylum, $10,000; New York University as a fund for the support of a chemical laboratory, $10,000; General Memorial Hospital, $2,500, and the sanitarium for Hebrew Children, $5,000.

Contagious Diseases.—During the week ended May 7, there were reported to the Sanitary Bureau 1,836 cases of measles, with 39 deaths; 391 cases of scarlet fever, with 23 deaths; 382 cases of diphtheria with 40 deaths; 1 case of smallpox; 78 cases of varicella; 411 cases of tuberculosis with 197 deaths; 18 cases of typhoid fever, with 8 deaths; and 77 deaths from cerebrospinal meningitis. There were also reported 359 deaths from pneumonia.

Improved City Milk Supply.—Dr. Darlington, health commissioner, has sent letters to all milk dealers and railroads entering the city in which he states that all milk with a temperature above 50 degrees F. will be seized and destroyed and the offenders prosecuted. The letter also stated that the section in the sanitary code relating to the adulteration of milk had been a dead letter for the past three years, but would, hereafter, be enforced strictly. Dr. Darlington has had his milk inspectors given state authority, and they are now investigating all the dairies throughout the state.

Ambulances at Brooklyn Bridge.—Police Commissioner McAdoo has planned to have stationed near the Manhattan entrance to the bridge every week day during the rush hours, from 5 to 7 o'clock, two police surgeons, two patrol wagons, and two patrolmen, so that persons injured may receive quick attention. It is probable that this plan will meet with considerable opposition, and will have to undergo some alteration. The Hudson Street and Governeur hospitals do this work at present, and take pride in their ambulance service. The city pays these institutions a small sum for each patient treated free, and they claim they could do all the work at less cost than the city, and naturally will resent the innovation.

Cerebrospinal Meningitis Increases.—The increased prevalence of this disease in the city causes some apprehension.

From the week ended March 5 to the week ended May 7 there were 357 deaths from this cause, while during the previous year it caused only 454 deaths in the entire state Cerebrospinal meningitis has usually held fifteenth rank among fatal diseases in this community, but if the present death rate should continue, it would reach the seventh place in the scale The epidemic, which began March 1, has so far had a mortality of about 90 per cent, and pediatrists in this city seem unable to make a prognosis of the cases under their care Patients who apparently should recover, die, and those who appear to be hopeless, recover

Menace to Purity of Water Supply.—New York wants pure water and has been willing to pay the necessary price to get it Some years ago a village on one of the chief tributaries of the Croton was condemned and obliterated, not because of any exceptionally unsanitary conditions, but because the existence of any village so near the source of water supply was thought to be a menace to the health of the city The city authorities had forbidden any bathing, boating or fishing in that stream At the present time important engineering works, such as road building and railroad improvement, are in progress there, requiring the services of many workmen Camps and barracks for the accommodation of several hundred men have been established near the site of the old village and these drain directly into the river The stream is constantly used by the workmen for bathing and laundry purposes Only the most primitive sanitary arrangements exist The people of New York do not relish the idea of having such an encampment simply for the convenience and profit of contractors The typhoid fever epidemic at Ithaca was attributed to just such an encampment on a stream from which the city received its water supply If present conditions continue the water supply of New York will be seriously and even dangerously contaminated

Buffalo

School Teacher Has Smallpox—A school teacher, who had never been vaccinated, was recently stricken with smallpox General vaccination in the public schools accordingly has been inaugurated

Hospital Staff Election—The election of the staff of the German Hospital resulted as follows President, Dr Charles H W Auel, vice president, Dr Marcello Hartwig, and secretary, Dr Frederick Zingsheim

Medical Curators—The council of the University of Buffalo selected the following men to fill vacancies on the board of curators in the medical department· Drs H J Nichols, Warren, Pa, H J Knickerbocker, Geneva, and Joseph Fowler, Benjamin G Long and Franklin W Barrows, Buffalo

Quarantined for Rabies—The townships of Boston, Milton and Malta in Saratoga County and Woodstock in Ulster County are now under quarantine by the state department of agriculture against rabies, which is more or less epidemic there All dogs are required to be tied or muzzled until the quarantine is raised

Against Tuberculosis—The Buffalo Charity Organization Society is preparing for a vigorous antituberculosis crusade The work will be in charge of Dr William Callahan, especially engaged for this work, and will be conducted among the crowded tenements of which Buffalo has a great many There are a great many so called "lungers" among these tenement houses, and with the co operation of the Buffalo Health Department an effort will be made to educate the people as to prophylaxis and disinfection

OKLAHOMA.

Hospital Chartered—A charter has been issued to the Helen M Gould Hospital at Chandler, with $50,000 capital

Again in Trouble—Rodermund, of unsavory repute in Appleton, Wis, by reason of his sensational aversion to vaccination, is reported to have been arrested recently at Oklahoma City on the charge of practicing medicine without a license

A Healthy Territory.—Dr Elmer E Cowdrick, Enid, secretary and superintendent of the territorial board of health, announces that the general health of the territory has never been so good as now There are no serious epidemics, and the most prevalent disease is measles in light form

Demands Revocation of License—The attorney general has filed a suit in the District Court against Dr Calvin D Gulley, Guthrie a graduate of the fraudulent Independent and Metropolitan Medical College of Chicago demanding that defendant's right to practice medicine in Oklahoma be revoked and that defendant forever be prohibited from further use of rights under said license

PENNSYLVANIA.

Philadelphia

New Italian Hospital—A charter has been asked for the establishment of a new Italian hospital in the thickly populated Italian section of the city, to be known as the Fabiana Italian Hospital

Wholesale Vaccination—Owing to the development of several cases of smallpox in a localized portion of the city, more than 500 persons in the immediate neighborhood were vaccinated During the crusade one fully developed case of smallpox was discovered

Health Report—The number of deaths in the city during the week ended May 14 was 520, being an increase of 52 over those of last week, and an increase of 46 over the corresponding period of last year There were 295 cases of typhoid fever reported, with 25 deaths For the preceding 7 days only 277 cases of typhoid were recorded

Pasteur Treatment in Philadelphia—Chief Abbott of the Bureau of Health is taking steps toward the establishment of a laboratory for the treatment of hydrophobia A case of hydrophobia was recently successfully treated in this city by the Pasteur method, in which the serum was received each day from the Pasteur laboratory in New York City

Hospital Appointments—The five men who successfully passed the examination for interne at St Joseph's Hospital were Drs C Menges Truschel, Wheeling, W Va, John P Donahue, Scranton, Pa, Owen O'Neill, New London, Conn, Albert Garton, Philadelphia, and E E Schlindwein, Erie, Pa ——The following men have been appointed to the resident staff of the Presbyterian Hospital Drs William R Butt, James T Williams, Sidney J Repplier, Ardrey W Downs, William G Niles, and Etrbert Z Giffin

Must Clean Street Cars—At the last meeting of the county medical society the subject of the infection bearing street-car upholstery was discussed Efforts are being made to have the companies clean the street cars immediately after each trip Dr Howard S Anders, president of the Pennsylvania Society for the Prevention of Tuberculosis, has issued a warning in the lay press to the public and the traction company of the spread of consumption and kindred diseases, which the filthy condition of public conveyances promotes

Bequests—By the will of the late Mrs Joseph B Townsend $5,000 is bequeathed to the Pennsylvania Hospital and the Jefferson Hospital for the establishment of free beds in memory of Mr Townsend, $1,000 each to the Visiting Nurse Society of Philadelphia, and the Children's Aid Society ——Bequests of $20,000 have been left the Methodist Hospital by the will of the late John N Doak, to be used to establish four free beds, to be called "Doak's free beds," in memory of the donor, his wife and parents, $200 additional has been devised for the necessary furnishings He also bequeathed $1,000 for the Home for Destitute Children

In the Hands of Their Friends—Dr Edward E Montgomery was operated on at St Joseph's Hospital, May 14, for mastoid disease He had suffered for some time with suppurative middle ear disease, but was thought to be free from mastoid involvement The symptoms, however, recently became more pronounced, and operation was decided on On account of his illness all arrangements for a reunion of the class of 1874 of Jefferson Medical College, and entertainment, June 6, have been abandoned ——Dr Harris A Slocum was operated on recently in the Pennsylvanaia Hospital for a large abscess of the neck He is progressing favorably

Against Illegal Practitioners—At the meeting of the county medical society, suggestions for a national crusade against illegal practitioners was discussed It was partially decided to bring the matter before the American Medical Association during its meeting at Atlantic City Dr Henry Beates, Jr, read a letter from the editor of THE JOURNAL, commending the society's action and advocating a national movement against unlawful practitioners ——The Homeopathic County Medical Society will appoint a committee of five to act in conjunction with the organized movement of the county medical society in their efforts to rid the city of illegal practitioners

RHODE ISLAND

Providence

Scarlet fever is very prevalent throughout the city

Personal—Dr Austin H Longfellow, who has been in Europe for three months, has returned home

New Quarters for Sick Sailors.—The U. S. Public Health and Marine-Hospital Service has secured a ward at the East Side Hospital.

School Medical Inspectors.—Drs. Ellen A. Stone and Charles E. Hawkes have been appointed city medical inspectors of schools, with a salary of $500 per annum each.

TEXAS.

Personal.—Dr. Frank D. Thompson, Fort Worth, has been elected to the chair of surgery in the Baylor University College of Medicine, Dallas.

Commencement.—Fort Worth Medical College held its annual commencement exercises April 7. Drs. Mary King Robbie, San Antonio, and Harry D. Nifong, Fort Worth, were given degrees "*Cum Laude.*"

Quarantine Modified.—As Mexico has consented to all the stipulations and restrictions contained in the governor's recent quarantine proclamation and has consented that Texas and the United States send sanitary inspectors into Mexico, the quarantine officers on the frontier have been ordered to admit all persons from Mexico into Texas not from a city infected last year, and even from these places, provided they have certificates from the state's sanitary inspectors that they had not been in such cities for five days.

State Society Election.—At the thirty-sixth annual meeting of the Medical Association of the State of Texas, held in Austin, April 26-29, the following officers were elected: President, Dr. Ferdinand E. Daniel, Austin; vice-presidents, Drs. John T. Moore, Galveston, Charles E. Cantrell, Greenville, and Walter Shropshire, Yoakum; secretary, Dr. Ira C. Chase, Fort Worth; treasurer, Dr. Robert F. Miller, Sherman; councilors—First District, Dr. Stephen T. Turner, El Paso; Second District, Dr. Preston C. Coleman, Colorado; Third District, Dr. David R. Fly, Amarillo; Fourth District, Dr. Charles M. Alexander, Coleman; Fifth District, Dr. Witten B. Russ, San Antonio; Sixth District, Dr. Henry J. Hamilton, Laredo; Seventh District, Dr. Thomas J. Bennett, Austin; Eighth District, Dr. Wesley A. Rape, Victoria; Ninth District, Dr. Henry B. Decherd, Galveston; Tenth District, Dr. Benjamin F. Calhoun, Beaumont; Eleventh District, Dr. S. R. Burroughs, Buffalo; Twelfth District, Dr. Garland B. Foscue, Waco; Thirteenth District, Dr. Joseph H. McCracken, Mineral Wells; Fourteenth District, Dr. Millington Smith, Sulphur Springs, and Fifteenth District, Dr. olman Taylor, Marshall; delegates to the American Medical ssociation, Drs. Sam R. Burroughs, Buffalo, Frank Paschal, San Antonio, J. T. Wilson, Sherman, Robert W. Knox, Houston, and James W. McLaughlin, Galveston; and alternates, Drs. James E. Dodson, Vernon, Thomas C. Whitehead, Del Rio, Charles M. Rosser, Dallas, William G. Jameson, Palestine, and Arthur C. Scott, Temple. The councilors met and elected Dr. Witten B. Russ, San Antonio, chairman, and Dr. Henry B. Decherd, Galveston, secretary. Houston was selected as the meeting place for next year.

GENERAL.

The American Medical Temperance Association.—The thirteenth annual meeting of this association will be held in the parlors of the Hotel Dennis at Atlantic City, June 8 and 9, 1904, at 9 a. m.

American Proctologic Society.—This organization will hold its sixth annual meeting at the Seaside House, Atlantic City, June 8 and 9. Sixteen papers are offered covering the field of this specialty.

Personal.—Dr. I. Rodriquez Barros, Santiago, Chili, is here to study the methods of teaching and practice in New York and Baltimore medical schools. He has been to Paris and London on the same mission. He will return to Chili in September.

Army Surgeons Appointed.—Out of a class of twenty, the following qualified for appointment as assistant surgeons, U. S. Army, with the rank of first lieutenant: Drs. L. J. Owens, Evansville, Ind.; Frank W. Weed, Baltimore, and Robert M. Culler, Reading, Pa.

American Pediatric Society.—The sixteenth annual meeting of this society will be held at Detroit from May 30 to June 1, and the program indicates that the proceedings are to be of a high value, both in the character of the papers to be presented and in the standing of the authors.

American Laryngological Association.—The twenty-sixth annual congress of this body will be held at Atlantic City June at the Hotel Chelsea. Among interesting subjects on gram we note that "The Mortality of Operations on and Throat" is to be discussed, "The Therapeutic cated Ointments," "Neuroses of the Upper Air Tract," and "Present Methods for the Treatment of Malignant Diseases of the Larynx."

The Yellow-Fever Prophylaxis Campaign.—The plan of campaign to prevent the reappearance of yellow fever on the Texas-Mexican border, as outlined in the weekly public-health reports, appears to be systematic. Laredo, Texas, where the epidemic prevailed last fall, is the geographical center of operations. The house-to-house inspection has been maintained there for more than two months, with the result that no case of yellow fever has been found. The city council has enacted ordinances embodying provisions recommended by the Public-Health and Marine-Hospital Service. Every case of fever found on inspection is immediately covered with mosquito netting until the case is proven not to be yellow fever, the government furnishing netting to persons too poor to buy it. At the same time, the water barrels in common use in Laredo are either treated with petroleum or covered with a close wire screen, the government also furnishing this screen when necessary. Laredo itself, therefore, at the present time, is considered free from yellow-fever infection. With Laredo as a central point, inspections have been made of all towns along the railroads from Laredo to San Antonio, from San Antonio to Corpus Christi, and from Corpus Christi back to Laredo. Several working parties have been sent out along these lines, each in charge of a physician, and composed of employes who have had experience in sanitary work in Laredo. These parties have visited, and are visiting, towns along these railroads, disinfecting where yellow fever prevailed last year, and demonstrating the method of destroying mosquitoes. They are organizing in each town a citizens' league for continuing the work, and also distributing short but comprehensive circulars describing the method and calling attention to the necessity of enforcing it. The triangle above described covers the principal places where yellow fever prevailed last year, but similar measures are being instituted in the region covered by another triangle, represented by a line drawn from Laredo to Corpus Christi, from Corpus Christi to Brownsville, and from Brownsville back to Laredo, and a new inspection station has been provided for at Rio Grande City, one of the principal crossings from Mexico into the southern part of Texas. Another triangle, which has been covered by inspections, is represented by a line drawn from Laredo north to Eagle Pass, thence to San Antonio, and from San Antonio to Laredo. In the Republic of Mexico, where there was so much yellow fever last year, there is no doubt that the Superior Board of Health is actively engaged in sanitary measures, and it has arranged to send prompt notification to Washington of any reappearance of the disease. The places infected last year are along the lines of three roads running from the Texas frontier, namely, the Mexican National from Laredo, the Mexican International from Eagle Pass, and the Mexican Central from El Paso. Through an understanding effected between the Publich Health and Marine-Hospital Service of the United States and the Superior Board of Health of Mexico, not only has the Superior Board of Health agreed to give prompt notification of the reappearance of yellow fever, but it has cheerfully acquiesced in visits from time to time of Public Health and Marine-Hospital Service officers to the sections named, for the purpose of confirming their good sanitary condition, and all places, almost without exception, where yellow fever prevailed in Mexico, north of the City of Mexico, have been inspected and reported on by the United States Public-Health Service. This smooths out matters, and enables the work to be carried on with success. It is too early to predict whether yellow fever will recur or not, but certainly in both Texas and the Republic of Mexico an active anti-mosquito warfare is being carried on, giving reasonable ground for hope that any considerable prevalence of the fever may be averted.

CANADA.

New Hospital Wing Opened.—A few days ago, in connection with the Toronto Isolation Hospital, a fine new wing was opened with accommodation for 100 additional patients. It cost $32.000.

Donation to Montreal General Hospital.—Hon. G. W. Stephens has given the Montreal General Hospital gold bonds of the Havana Electric Railway Company to the value of $5,000, for the endowment fund. An effort is being made to raise $500.000, but thus far only $60.500 has been raised.

Personal.—Dr. Halsey, lecturer in pharmacology and therapeutics in McGill University, has accepted the chair of therapeutics and clinical medicine in Tulane University, New Orleans. Dr. J. W. Scane, the registrar of McGill Medical Faculty.

succeeds Dr. Halsey, and in addition will continue the work of Dr. Halsey in the Eddie Morris Research Laboratory, together with his duties as registrar.——Dr. W. T. Connell, professor of pathology in Queen's University, Kingston, Ont., has been appointed assistant bacteriologist to the Ontario Board of Health.

Medical Institute for Toronto.—There has just been purchased in Toronto a fine property in Queen's Park by the medical fraternity of Ontario and Toronto, which hereafter will be the home of the Ontario Medical Library, as well as the meeting place of the medical societies of Toronto. This step is an important one, and looks toward the amalgamation of the medical societies of Toronto into an academy of medicine. Dr. J. F. W. Ross, president of the Ontario Medical Association, and also of the Ontario Medical Library Association, is the leading spirit in the transaction.

College Reorganization.—It is proposed to reorganize the corporation of the Royal College of Physicians and Surgeons of Kingston. Owing to university trouble, Queen's Medical Faculty, in 1866, was formed into this corporation under royal charter. In 1892 the medical college again became affiliated with Queen's, but the charter of the royal college remained. Now the intention is to utilize its examining powers for the granting of fellowships, viz., F.R.C.P.S. This degree will be open to physicians of five years' standing, and will be secured only on examination and on approved thesis. The standard will be made the highest for any medical degree in Canada. The Hon. Dr. Sullivan will be the president of this college, he being one of those to whom the original charter was given.

FOREIGN.

German Soldiers Sick.—Among the German troops in southwest Africa, typhoid fever is running a very fatal course. This, with the losses in the conflict with the natives, and the fact that they are far from reinforcements, makes a serious outlook for the troops.

Exhibition of Otology.—There is to be an exhibition of pathologic specimens and of instruments and apparatus in connection with the approaching International Congress of Otology. Those wishing to exhibit specimens, drawings, photographs, instruments, etc., are requested to inform the exhibition committee, Drs. Guément and Lafite-Dupont, or the president of the congress, Dr. E. J. Moure, Cours du Jardin Public, 25. Bordeaux, France, before July 1. As previously announced, the congress will open August 1, at Bordeaux.

The German Congress of Internal Medicine.—The twenty-first German Congress of Internal Medicine was held at Leipsic April 18 to 21, the president, Professor Curschmann, of Leipsic, in the chair. Marchand of Leipsic and Romberg of Marburg, one of Curschmann's former pupils, delivered the main addresses on the one subject announced for discussion, "Arteriosclerosis." It is proposed to lengthen the interval between these congresses to two years instead of having them an annual institution. The next meeting will be held at Wiesbaden, and von Strümpell will preside. Those present at the congress comment on the scant attention paid to bacteriology in comparison with former congresses.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PATENT MEDICINE ADVERTISING IN MAGAZINES.

DR. FRANK C TODD, Minneapolis, has had some interesting correspondence with *Everybody's Magazine.* He received a letter—evidently a circular letter—in which the publishers of the magazine stated that they were after the quacks, and asked him to lend a hand. They stated that they "decline to carry any patent medicine or other fraudulent or otherwise objectionable advertisements." "Publishers have no right to lend their pages to help swindle the public," etc.

To this Dr. Todd replied that he had begun to fill out a subscription blank as an expression of his approval of the commendable plan of the magazine, when he discovered that it had a number of such advertisements as those of Dent's toothache gum, Madame Hessler's hair restorer and the Morley artificial ear drum. He called attention to the advertisement of the latter, in which occurred the phrase: "No case of deafness which it will not benefit."

The publishers of *Everybody's Magazine* in reply made a decided backdown from their previous stand. They stated, "If you declined to purchase all magazines and publications that carry patent medicine, fake, financial and other objectionable advertisements, you would have so little reading in your home that you would have to read your medical books or Shakespeare. You have heard of the man who lived so upright a life that he leaned backward. We don't want to be in that condition. We could name half a dozen magazines that are running anywhere from $1,000 to $5,000 worth of advertising monthly that we do not take."

This inconsistency gave Dr. Todd a good opening, and we quote a few sentences from his reply: "I have heard of many fraudulent methods practiced by advertising charlatans, but none more brilliant than yours. It certainly is a good graft if it works. Since you have considered all of its advantages it is hardly necessary for me to point out that by eliminating many quack advertisements and making the claim that you 'decline to carry *any* patent medicine or other fraudulent and otherwise objectionable advertisements,' you are 'doing more harm than a magazine containing many such fraudulent advertisements, but making no claim to decency, because many readers will be led to believe that those which you do publish are trustworthy. Such being the case, these fortunate few advertisers should be able to pay well for such consideration. While in your first letter you stated that you declined to carry 'any patent medicine or other fraudulent advertisements,' in your last you admit your claim to be a myth, but think you should be considered upright because you carry less than some other magazines— on the principle that it is less criminal to steal $1,000 than to steal $5,000. It is difficult to determine how you make your selection, certainly not on the degree of fraud; perhaps it depends on their financial standing. I am aware that there is at least one newspaper in this country which conscientiously follows the plan of only inserting those advertisements which are not fraudulent, and I am told on good authority that it is made to pay well. I believe that if you honestly carried out the claim which you made in your first letter you would find that aside from doing your plain duty you would find it the best plan from a business standpoint."

SHRINKAGE OF SPECIMENS BY FORMALIN.

INDIANAPOLIS, May 6, 1904.

To the Editor:—Can you tell me what the approximate shrinkage in size of a gross pathologic specimen is after preservation in formalin; also shrinkage in weight? There certainly is considerable reduction in either case. HELENE KNABE.

ANSWER.—It is impossible to give an exact answer to this question, for the change in weight must depend entirely on the nature and condition of the organ and the strength of the solution in which it is placed. If a soft, pulpy tissue is placed in a strong solution of formalin the amount of contraction of the proteid coagulum formed by the action of the chemical may reduce the size appreciably, whereas in such an organ as the kidney or liver formalin of ordinary strengths used in laboratory work has little effect. For example: a heart preserved in Kaiserling solution, 20 per cent. formalin plus certain salts, after standing for six months weighed 25 grams less than when fresh: a lymphosarcoma changed in the same space of time from 1350 grams to 1300; whereas a lung with pneumonia in one lobe, that had been in the fluid for two weeks, increased from 950 grams to 1300, presumably from the taking up of fluid in the portions of the lung that were not consolidated.

HAY-FEVER SERUM.

WILLIS, KAN., May 5, 1904.

To the Editor:—Where can I procure Dunbar's serum for the treatment of hay fever, also directions how to use it? J. J. C.

ANSWER.—This serum was referred to in an article in the *Muenchener med. Wochenschrift*, No. 23, 1903, and abstracted in full in THE JOURNAL, July 11, 1903, p. 139. It was editorially noticed in the same number. The serum can probably be procured by addressing Professor Dunbar, Hygienisches Institut. Hamburg, Germany.

THE FICKER TYPHOID TEST.

DR. L. A. SUGGS, Fort Worth, Texas: In reply to your question as to where you can obtain the Ficker typhoid test. Ficker, in his report, did not give the formula of his preparation, but stated that it would be manufactured for the market by the firm of Merck at Darmstadt. As it must be fresh, it needs to be specially imported, and possibly Merck's branch office in this country will secure it for you.

Marriages.

E. O. HAYES, M.D., Drop, Texas, to Miss Kittie Wileman of Denton, Texas, May 5.

LOUIS L. BRYANT, M.D., to Miss Matilda Crane, both of Cambridge, Mass., April 12.

John Samuel Abney, M.D., Pineville, Ala., to Miss Lena Winn of Atlanta, Ga., May 1.

James L. Massey, M.D., Lubeck, W. Va., to Miss Lizzie McBride of Sandyville, W. Va., May 1.

Thomas C. Burch, M.D., Metasville, Ga., to Miss Pauline Strothers of Lincoln County, Ga., April 27.

James Raynor Whiting, M.D., New York City, to Miss Mildred Taylor of Poughkeepsie, N. Y., May 7.

Henry M. Farr, M.D., to Miss Katherine Chambers, both of Mount Pleasant, Iowa, at Monmouth, Ill., April 29.

Francis Herbert Poole, M.D., Dunn-Loring, Va., to Miss Hettie Bauer of Bel Air, Md., at Great Falls, Mont., April 27.

William Hungerford Burr, M.D., Wilmington, Del., to Miss Editha Lynde Geer of Hartford, Conn., at San Marcial, N. M., May 3.

Deaths.

Roberts Bartholow, M.A., M.D., LL.D., died at his home in Philadelphia from a nervous disease of long standing, May 10, aged 72. He was born at New Windsor, November 28, 1831, took his degree in arts at Calvert College, and his medical degree at the University of Maryland, Baltimore in 1852. He then entered the medical department of the Army, at the head of the class of candidates, and served as surgeon from 1856 to 1864. During this time, he took part in expeditions to Utah, New Mexico, and the great plains of the West. When the outbreak of the Civil War occurred he was attached to the military post of Fort Bridger, Santa Fe, N. M., and was ordered from there to Washington to take charge of the Government Hospital. In these unquiet times, thanks to the abundant experience of war, he acquired that profound knowledge of pathologic anatomy to which his skill and success in the treatment of disease, was undoubtedly in great measure to be ascribed. At the McDougall General Hospital, Fort Schuyler, N. Y., he wrote for the use of the government "A Manual of Instructions for Enlisting and Discharging Soldiers." He resigned from the Army in 1864, and began the practice of medicine in Cincinnati. Here he became a professor in the Medical College of Ohio. He had previously taught military medical jurisprudence in the Army Medical School. From Cincinnati, he was summoned, in 1879, to the chair of materia medica and therapeutics at Jefferson Medical College, Philadelphia. Here he completed his treatise on "Therapeutics," and wrote his "Practice of Medicine." He devoted himself actively to the work of the college until 1893, when he became professor emeritus. From this time and until a few days before his death, he devoted himself to the almost unremitting practice of his profession, and in addition wrote the following books: "Medical Electricity," which went through three editions, "A Manual of Hypodermatic Medication," which went through five editions, and "Cholera," and revised successive editions of his two chief text-books, the "Practice of Medicine" and the "Therapeutics," which reached eight and eleven editions respectively. As regards Dr. Bartholow's views on the subjects of pharmacology and therapeutics, on physiologic chemistry, etc., in which he was, in a special sense, more deeply versed than the practical nature of most of his writings show, it may be of interest to observe that, though a firm believer in the effectiveness of drugs, in the latter years of his life, he became more and more convinced of the utility of dietetic and hygienic methods of treatment. He enjoyed an unusual power of discriminating the virtues and merits of these separate forces in the genius of healing. The results of purely laboratory experiment, he adopted with all the liberality that they can justly demand, but he became impressed with the frequent nullity of some of the too hasty and general statements with which modern literature is burdened. He was a fellow of the College of Physicians of Philadelphia, a member of the American Philosophical Society, and an honorary member of the Royal Medical Society of Edinburgh and the Society of Practical Medicine of Paris

Roberts Bartholow, M.A., M.D., LL.D.

Joseph D. Titcomb, M.D. Medical School of Maine at Bowdoin College, Brunswick, Maine, 1881, a member of the American Medical Association, Minnesota State Medical Society, St. Louis County Medical Society, Inter-Urban Academy of Medicine, Chicago Ophthalmological Society and Academy of Ophthalmology and Oto-Laryngology; one of the most prominent ophthalmologists of the northwest; oculist to the Duluth and Iron Range Railroad and to St. Mary's and Red Cross hospitals, died at his home in Duluth, May 6, after a short illness, from pneumonia, aged 45.

Crayke S. Priestley, M.D. University of Pennsylvania, Philadelphia, 1894, son of Dr. James Taggart Priestley, a member of the American Medical Association, Iowa State Medical Society, Polk County Medical Society and Des Moines Pathological Society; professor of dermatology in the Drake University College of Medicine, Des Moines; a young physician of great promise, died at his home in Des Moines, May 13, from pneumonia, after an illness of four days.

Julius A. Freeman, M.D. American Medical College, Cincinnati, 1850; Chicago Medical College, 1877; a member of the American Medical Association; ex-president of the North Central Illinois Medical Association, and Kendall County Medical Society; surgeon of the One Hundred and Fourth Illinois Volunteer Infantry in the Civil War, died at his home in Millington, Ill., May 8, from the effects of a runaway accident, aged 76.

William Waterworth, M.D. Bellevue Hospital Medical College, New York City, 1878, a member of the American Medical Association, New York State Medical Association, and Kings County Medical Society; surgeon to the Brooklyn Eye and Ear Hospital, died May 11, at his home in Brooklyn, from sarcoma, aged 53.

Truman Burgess Ellis, M.D. State University of Iowa College of Medicine, Iowa City, 1881, a member of the American Medical Association; secretary of the Harrison County (Mo.) Medical Society; a practitioner of marked ability, died at his home in Bethany, April 28, after an extended illness, aged 48.

David O. Bennett, M.D. Rush Medical College, Chicago, 1870, surgeon general of the South Dakota National Guard, ex-state senator, and veteran of the Civil War, died recently at his home in Clark, S. D., after an illness of one week, aged 61.

Andrew J. Leitch, M.D. Medical Department of Western Reserve University, Cleveland, 1871, some-time mayor and city treasurer of Niles, Mich., who retired from practice in 1898, died at his home in Niles, May 7, from paralysis, after an invalidism of nearly a year, aged 56.

Clinton Cushing, M.D. Rush Medical College, Chicago, 1865, retired, a member of the American Medical Association, formerly a member of the faculty of the University of California, and a resident of San Francisco, died suddenly, May 10, at his home in Washington, D. C.

A. J. Campbell, M.D., for more than half a century a practitioner, for 9 years physician of Knox County, Tenn., and a surgeon in the Confederate service during the Civil War, died at his home in Knoxville, May 4, after an illness of six weeks, aged 74.

Henry Levy, M.D. New York University, 1878, a member of the American Medical Association, a member of the attending staff of the City Hospital, Perth Amboy, died at his home in that city, May 5, after a lingering illness, aged 47.

Jacob C. Lee, M.D. Hospital College of Medicine, Louisville, 1877, who had been in failing health for a long time, from an operation wound, shot and killed himself at his home in Lee's Summit, Mo., while despondent, May 8, aged 46.

Martin L. Shanks, M.D. Columbus (Ohio) Medical College. 1882, a member of the Cass County Medical Society, died at his home in Casselton, N. D., May 5, from Bright's disease, after an illness of two months, aged 55.

John E. Miller, M.D. Starling Medical College, Columbus, Ohio, 1889, a member of the state legislature, died at his home in Darbyville, Ohio, from diabetes, May 8, after an illness of two weeks, aged 43.

John W. Adams, M.D. Beaumont Hospital Medical College, St. Louis, 1887, professor of physical diagnosis in the St. Louis College of Physicians and Surgeons, died at his home in St. Louis, April 14.

Josephus Jordan, M.D. Medical Department of the University of Cincinnati, 1848, one of the founders of the Muskingum County Medical Society, died at his home in Zanesville, Ohio, May 2, aged 81.

William F. Miller, M.D. University of Louisville, 1843, one of the oldest practitioners of Louisville, died at the home of his daughter in that city, May 10, after an illness of one year, aged 83.

J. M. Woodward, M.D. Medical College of the State of South Carolina, Charleston, 1878, died at his home in Montmorenci, S. C., April 30, from disease of the stomach and liver, aged 55.

D. C. Phillips, M.D. Kentucky, of Millerstown, Ky., died at the home of his son near White Mills, Ky., from paralysis, after an invalidism of nineteen months, April 22, aged 80.

John W. Brown, M.D. University of Pennsylvania, Philadelphia, 1870, of Reading, Pa., died at the Pennsylvania State Hospital, May 1, after an illness of ten months, aged 69.

Harper Franklin Tickle, M.D. Baltimore Medical College, 1894, died at his home in Charleston, W. Va., May 5, from erysipelas, after an illness of three weeks, aged 41.

James B. Carruthers, M.D. Toronto University Medical Faculty, 1886, of North Bay, Ont., died suddenly while making a professional call, March 17, from heart disease.

William Richardson, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1866, died at his home in Burlington, Ont., March 14, after a long illness, aged 61.

John L. Dodge, M.D. University of Louisville, 1887, ex-president of the Bolivar County Medical Society, died suddenly at his home in Rosedale, Miss., May 10.

Henry A. Wise., M.D. University College of Medicine, Richmond, Va., 1896, of Williamsburg, Va., died at St. Luke's Hospital, Richmond, May 5, aged 30.

David H. Muir, M.D. College of Physicians and Surgeons, New York City, 1867, thrice mayor of Truro, N. S., died at his home in that city, March 11, aged 65.

George Payson Jefferds, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1844, retired, died at his home in Bangor, Maine, May 9, aged 88.

Marcus A. Taylor, M.D. Missouri Medical College, St. Louis, 1878, died at his home in Honey Grove, Texas, February 2, from pneumonia.

Leroy M. Nifong, M.D. Barnes Medical College, St. Louis, 1897, died suddenly from heart disease at his home in Modesto, Ill., April 30.

Milo Bloomer, M.D. Cincinnati College of Medicine and Surgery, 1864, died recently at his home in Dodge, Neb., from tuberculosis.

Michael Kelley Collver, M.D. University of the Victoria College, Cobourg, Ont., 1882, died at his home in Stevensville, Ont., March 11.

Albion P. Topliff, M.D. Dartmouth Medical School, Hanover, N. H., 1867, died at his home in Portland, Maine, May 8, aged 60.

Earl B. Baker, M.D., died from consumption, April 29, at the home of his father in Hickory, N. C., after a prolonged illness.

Edward Brooking Schley, M.D. New York, 1861, died at his home in Waverly Hall, Ga., May 5, from meningitis, aged 66.

Alfred G. Belleau, M.D. McGill University, Montreal, 1862, district coroner for Quebec, died March 9, aged 63.

Daniel S. Lloyd, M.D. Toronto School of Medicine, 1875, died at his home in West Bay City, Mich., April 18.

Leander Riggs, M.D. Cleveland Medical College, 1870, died at his home in Elizabeth, Pa., May 3, aged 58.

J. W. Lyle, M.D. Texas, died at his home in Springtown, Texas, January 25, from Bright's disease.

John Milton Duff, M.D., of Pittsburg, Pa., died May 14. Further mention will be made next week.

John Christopher Richardson, M.D., died at his home in Burlington, Ont., February 25, aged 38.

Lemont S. Crandall, M.D. New York, died recently at his home in Lamberton, Minn., aged 69.

Marx Pomeranc, M.D. University of Würzburg, Germany, 1866, of Chicago, died March 2.

Edward P. Goodrich, M.D., died at his home in New Haven, Conn., May 6, aged about 60.

Miscellany.

YELLOW FEVER IN BRAZIL.

The Report of the French Yellow Fever Commission Operating at Rio Janeiro, Brazil.

In 1901, a commission, composed of Messrs. Marchoux, Salimbeni and Simond of the Pasteur Institute, was appointed to conduct investigations regarding the etiology of yellow fever and the mosquito *Stegomyia fasciata* in the transmission of the disease at Rio Janeiro. This commission rendered a report, which was published in the annals of the Pasteur Institute in November, 1903.

The commission concludes that the infecting principle in the blood of yellow-fever patients remains active for five days when kept in defibrinated blood under liquid vaselin, but that at the end of eight days the infectivity of the blood has disappeared. They deduce as a result of their experiments that the blood contains this infecting agent during only the first three days of the disease.

They deduce further from their experiments that the blood serum of a yellow-fever convalescent possesses clearly preventive properties. They further deduce as the result of experiments on eleven individuals made in hospital that the blood serum of a yellow-fever convalescent possesses therapeutic properties of considerable curative value.

In regard to the mosquito *Stegomyia fasciata*, their work is particularly valuable. They point out that the habits of the *Stegomyia fasciata* differ very much from those of most other mosquitoes. One of the marked peculiarities of the species is its extreme susceptibility to differences of temperature. It manifests its greatest activity when the thermometer stands at 25 C. Beyond 39 C. the insect dies. At 15 C. to 16 C. the insect becomes inert and ceases to bite. At 12 C. to 14 C., it is benumbed and flies with great difficulty. All of the acts of its life are much influenced by the temperature of the surrounding atmosphere.

The female stegomyia alone bites. The female is perfectly capable of biting immediately after metamorphosis. Within twenty-four hours she bites readily. Within forty-eight hours of metamorphosis and at temperatures between 26 C. and 35 C. she will bite readily at any hour of the day if recently fecundated, but especially beginning at about 11 o'clock in the morning. If the temperature is between 19 C. and 25 C., she bites less readily. At temperatures between 14 C. and 18 C., she does not seek to bite at all unless artificially warmed by contact with the skin of the victim. She bites less readily between 22 C. and 25 C., but a temperature of 27 C. to 30 C. is that which suits the insect best.

LAYING.

After having filled herself with blood, the female seeks water on which to lay her eggs. Laying is generally effected during the night. The average number of eggs is from 70 to 80. Temperature has an influence on this act, it taking place most readily at a temperature of 27 C. to 28 C. during the night, under which conditions of temperature laying takes place within forty-eight hours after biting. If the night temperature is from 25 C. to 27 C., the laying takes place on the fourth or fifth day. If between 20 C. and 25 C., it is possible up to the seventh or eighth day, and if below 20 C., it may be delayed up to twenty-six or twenty-seven days.

HATCHING.

Hatching is best accomplished at a temperature of 28 C., at which temperature the eggs hatch on the second or third day. If the temperature is as low as 25 C., it takes place on the fourth day. If between 20 C. to 25 C., hatching takes place on the fifth to seventh day, but does not proceed with regularity. The eggs do not seem to hatch at a temperature below 20 C., though they may be preserved at much lower temperatures, even as low as zero, but if brought back to favorable conditions of temperature, hatching proceeds with considerable regularity. The eggs may be immersed in water and a considerable proportion of them still hatch. If dried before immersion, their preservation is better assured.

HABITS.

The stegomyia is a domestic mosquito, preferring for laying her eggs deposits of water such as are found in the interior and in the immediate neighborhood of houses. It seems to thrive better in rain than in spring water.

PUPAL STAGE.

With temperatures ranging from 26 C. to 27 C. by night and 28 C. to 31 C. by day, the larvæ of the stegomyia arrive at the pupal stage seven days after hatching, and at the perfect insect stage on the ninth day. In a majority of instances, however, this latter stage does not occur until the tenth day. At temperatures below 22 C., larvæ may take forty to sixty days to be transformed into pupæ, and these pupæ three to five days to become perfect insects. The ordinary length of the pupal stage is thirty to fifty hours. Larvæ do not perish at a temperature in the neighborhood of zero, but under these conditions they grow very slowly. Sea water is fatal to the larvæ of the stegomyia, but in a mixture containing one-fifth sea water and four-fifths fresh water, they develop, attaining the pupal stage on the eleventh day, and the perfect insect stage on the thirteenth day. In brackish water containing one-third sea water, they die in a few hours. Water containing 1/1000 of its weight of soap kills the larvæ in five minutes. In solutions containing 1/10,000 they do not develop. In solutions containing 1/200,000 they developed normally.

ADULT CONDITIONS.

Blood seems to be necessary to enable the female stegomyia to lay. Human blood appears to be particularly grateful to them. Except in the early days of their existence, when she bites at any time, the female stegomyia prefers to bite by night rather than by day. She may, therefore, be considered as a night mosquito.

LONGEVITY OF STEGOMYIA.

While the stegomyia is very easily reared under proper conditions of temperature and moisture, it dies rapidly when placed in dry air and without blood as food. In captivity they attain the age of two months with comparative ease, but beginning from the fortieth day, mortality among them becomes large, being greater among the males than among females. In the laboratory, females have attained the age of 89, 90, 93, 97, 105 and 106 days. It did not seem possible to preserve males more than fifty days. In the free state, the insect can not live so long, much of its vigor being lost within a short time after its evolution, and its resistance is much diminished by danger and destruction of its scales. High temperatures from 36 C. to 39 C. are unfavorable to the life of a mosquito.

RACIAL PREFERENCES OF THE STEGOMYIA.

The stegomyia will bite individuals of any race, but manifests in Brazil a preference for the white over the Indian and the Indian over the negro. She manifests considerable repugnance to the negro, and bites only after quite prolonged contact. Among the white races she attacks by preference individuals with a thin skin and a fresh color.

CLIMATIC CONDITIONS FAVORABLE TO THE STEGOMYIA.

Every warm and moist climate whose temperature at certain seasons varies between 25 C. and 30 C., is peculiarly suited to it. Between 22 C. and 25 C., it multiplies, but more feebly. Average night temperatures below 22 C. are accompanied by a rapid disappearance of the species. The stegomyia resists sudden changes of temperature badly.

INFLUENCE OF ALTITUDE.

In the vicinity of Rio Janeiro the stegomyia is seldom encountered at an altitude of more than 400 meters. At Petropolis, at an altitude of 800 meters, it is not found naturally, and perishes when introduced. It appears, however, that this is not due to the altitude itself, but to the lowered nightly average of temperature.

RELATION OF OTHER MOSQUITOES TO YELLOW FEVER.

The commission concludes that no other mosquito found at Rio Janeiro, or in the vicinity has any relation to the transmission of yellow fever. The commission draws the following deductions in regard to the transmission of yellow fever as a result of their observations:

1. That yellow fever is not transmitted in nature, either by direct contact with the patient or by contact with personal effects or by his excretions.

2. That the transmission is effected by the biting of mosquitoes, and that the only dangerous species, at least in the region in which our researches have been conducted, is the *Stegomyia fasciata*.

3. That this transmission never takes place during the day while the sun is above the horizon.

In regard to protection against the infection of yellow fever, the commission deduces that "the introduction of merchandise is unattended with danger at any time."

In regard to arrivals from a territory infected with yellow fever at a port or place where the disease does not prevail, the commission deduces that "it is perfectly useless to inflict a quarantine if stegomyiæ do not exist in the country at the time of arrival, since transmission can only be effected by this intermediary."

MEASURES LOOKING TO THE DESTRUCTION OF THE STEGOMYIÆ.

The observations of the commission present no points of particular interest for us in the United States. It is gratifying to find, however, that they have arrived at practically the same conclusions as have been arrived at as the result of experiment and observations in the United States.

CONCLUSIONS.

The general conclusions of the commission may be summed up as follows:

1. The serum of a patient on the third day of the disease is virulent.

2. On the fourth day of the disease, yellow-fever blood no longer contains any virus, even when the fever is high.

3. One-tenth of a cubic centimeter of virulent serum injected under the skin is sufficient to cause yellow fever.

4. The virus of yellow fever rubbed on a blister of the skin, made by removing the epidermis, does not give the disease.

5. In the serum of the patient, the virus of yellow fever passes through a filter Chamberland F without dilution.

6. Under the same conditions it does not appear to pass through filter B.

7. Virulent serum preserved exposed to the air at a temperature of 24 C. to 30 C., is inactive at the end of forty-eight hours.

8. In defibrinated blood, preserved under liquid vaselin at a temperature of 24 C. to 30 C., the microbe of yellow fever remains living for five days.

9. At the end of eight days defibrinated blood, kept under the same conditions, no longer contain active virus.

10. The virulent serum becomes harmless after heating for five minutes at 55 C.

11. A preventive injection of serum heated for five minutes at 55 C., confers a relative immunity which, followed by inoculation with a very small quantity of virus, may become complete.

12. The injection of defibrinated blood, kept in the laboratory under liquid vaselin for eight days at least, confers a relative immunity.

13. The serum of a convalescent is endowed with clearly preventive properties.

14. The immunity conferred by the serum of the convalescent is still in evidence at the end of twenty-six days.

15. The serum of a convalescent appears to have therapeutic properties.

16. As has been proved by Reed, Carroll and Agramonte, yellow fever is produced by the bite of the *Stegomyia fasciata*.

17. To be able to produce the disease in man, this mosquito must be previously infected by absorbing the blood of a patient stricken with yellow fever during the first three days of the disease.

18. The infected mosquito is only dangerous after an interval of twelve days from the time when it has ingested virulent blood.

19. The bite of two infected mosquitoes may cause a serious illness.

20. The mosquito appears to be more dangerous in proportion that her bite is delayed after the time when it has become infected.

21. The bite of infected mosquitoes does not invariably give yellow fever.

22. When the bite of infected mosquitoes has been without effect, there is no immunity conferred against the injection of virulent serum.

23. In the neighborhood of Rio de Janeiro, as in Cuba, no other mosquito than the *Stegomyia fasciata* is concerned in the transmission of yellow fever.

24. Contact with a patient, his personal effects, or his excretions, is incapable of producing yellow fever.

25. Outside of the bite of the infected stegomyia, the only means known of producing the disease is the injection into the tissues of a susceptible individual of blood from a patient collected in the first three days of the disease.

26. Yellow fever can only assume a contagious character in regions where the *Stegomyiæ fasciata* prevail.

27. The prophylaxis of yellow fever rests entirely on measures taken to prevent *Stegomyia fasciata* from biting the individual sick and then a healthy individual.

28. It must be borne in mind that the period of incubation of yellow fever may be prolonged up to thirteen days.

29. The *Stegomyia fasciata* is frequently infected by moulds, yeasts and by sporozoa. No parasite of this species recognized up to this time has any causal relation to yellow fever.

30. Neither in the mosquito nor in the blood have we succeeded up to this time in discovering the causal agent of yellow fever.

Shotgun Quarantine.—In his annual address as president of the Texas State Medical Association, delivered at the recent session of that body, Dr. Paschal had the following to say on quarantine:

> Every county in this state has the right to decree a quarantine against another county without the leave or sanction of the governor or state health officer whenever in the opinion of the county commissioners and county health officers some infectious or contagious disease justifies such action. The county health authorities are superior under the law to the state health officer.
>
> As an illustration of this, the yellow fever episode of last year will serve full well. Trains carrying food were in some instances not allowed to pass through one county into another county, but were held up with shotguns by the county authorities. It has been stated that a well of water happened to be just across a county line, and water could not be taken from it by residents of the other county without those going for a bucket of water being placed in quarantine for five days; also, that a graveyard was just across a county line, a man's wife died, and the husband was told he would be allowed to bury his wife in the graveyard, but that he would have to go into quarantine camp for five days. It was demanded that carloads of ice should be disinfected, that iron machinery should b[illegible]s should be perforated, and newspapers [illegible] before they could be sent by mail. Indeed, [illegible] to even attempt to recount the foolish occurrences connected with the quarantine last year. The hardships and privations that hundreds were subjected to will never be known, but long remembered by those who had to endure them.
>
> The interruptions and commercial losses occasioned by quarantining infectious but controllable diseases are too great to be tolerated. Our knowledge concerning the propagation of yellow fever and other infectious and communicable diseases has been obtained after the most searching and convincing investigations, made both in this country and in Europe. They are of a nature to enable us to employ intelligently and effectively scientific and rational measures in preventing their spreading. We should accept the facts derived from these investigations and relegate to the dark ages obsolete theories and not continue perpetuating measures employed when we were ignorant of their causation and manner of dissemination. If interstate and municipal quarantining against yellow fever is continued we must acknowledge that it will be either from fear of public censure or from unwillingness to accept as positive the demonstrated proof that yellow fever is not conveyed by fomites, but by the mosquito. We should stand or fall by truths. Can we accept the results obtained at Havana, which was formerly a hotbed of yellow fever, and where to-day it has practically ceased to exist, as being due to the application of rational methods in handling the disease. If we can, we certainly ought to apply them wherever yellow fever is encountered.
>
> I see no more reason why cities in the south should suffer by quarantine against yellow fever than that New York or Philadelphia should do so. Yellow fever has visited Philadelphia and New York, and is liable to invade them again. If it should, could the commerce of these great cities be stopped by quarantine? I believe not.
>
> If we accepted the scientific teachings of the day relative to the causation and propagation of yellow fever and other communicable diseases and acted accordingly, it would inspire more confidence in the public and prevent upsetting commerce and the uncalled-for criticisms and censure of boards of health, health officers and physicians who dare express their belief regarding the existence of these diseases. Whenever yellow fever visits a city. our health authorities are held up to ridicule, to threats and abuse by those who, though ignorant of the disease, flaunt their knowledge of it before the public and their great ability to diagnose it by no other means than by the smell. Unfortunately, a division of sentiment among members of our own profession has proverbially occurred wherever this disease has made its appearance, some claiming it to be yellow fever and others that it is not. This is caused by quarantine and its injury to commerce and not from the actual dangers to human life. If rational methods were employed in handling the disease it would be more easily controlled. Physicians who now hide their cases from health authorities for fear of criticism, or on the presumption that they are doing the commercial interests of their community a good deed, and expect thereby to receive commendation, would probably take the necessary precaution to prevent others from being infected by reporting their cases and would not allow them to remain hidden and continue a menace to the public health.

Arrested Pulmonary Tuberculosis.—F. Parkes Weber, London, discusses this subject from the clinical point of view in the *Zeitschrift f. Tuberkulose*, v. 3, 1904. He thinks it is important to discriminate between the latent, arrested disease and that which is practically the foundation for an existing progressing tuberculosis. This distinction is rendered difficult by the fact that probably every person harbors tubercle bacilli and is, therefore, "tuberculous." This point is especially important for life-insurance examiners. It is not necessary to reject every one who harbors the bacilli or has once expectorated blood. He cites the favorable experience of the English companies in this respect, giving a number of details, to show their success in the opposite course. An arrested tuberculosis is liable to be fanned into a flame by either of two factors, trauma or new and mixed infection.

Association News.

RATES FOR ATLANTIC CITY.

Special Trains Will Carry Large Delegations to the Atlantic City Session.

The excellent railroad rates which have been granted to the Fifty-fifth annual session of the American Medical Association at Atlantic City have been mentioned in The Journal, April 30. The exact details can be secured from railroad ticket agents.

In the Central and Western Passenger Associations, the tickets will be sold May 31, June 1, 2, 4 and 5. Stop-over will be allowed at Philadelphia on going trip up to June 6, provided that the ticket is deposited at the Philadelphia railroad office immediately on arrival. Tickets are good for return from June 6 to June 13, and within this limit stop-over is to be allowed at Philadelphia, New York City and Baltimore. Those who wish to make a side trip from Philadelphia to New York City, will find that the round trip from Philadelphia to New York will cost $4, and five days will be allowed in which to return. The journey between the two points requires two hours' time.

Chicago will be the focus of travel for much of the western territory, and to Chicago will come special trains from the west and southwest. Two carloads of Iowa physicians and their friends are already reported as arranged for.

The special train out of Chicago which will carry these passengers is the American Medical Association special train over the Pennsylvania Lines. This will leave Chicago Sunday afternoon. June 5, at 2 o'clock, and will run through to Atlantic City without change. It will arrive at Atlantic City at 5 p. m., Monday, June 6. The rate from Chicago will be $20.25. Further information and reservations of berths in sleeping cars may be had from the representatives of the Pennsylvania Lines.

Trains on Other Railroads.

There are a number of railroad lines leaving Chicago for Atlantic City, and all of them will take special pains to accommodate physicians who will travel thereon. The Baltimore & Ohio Railroad will sell tickets for the dates mentioned above at the rate of $20.25 for the trip from Chicago to Atlantic City and return. Their regular trains leave at 10:40 a. m. and 3:30 p. m. Both of these trains are equipped with Pullman sleeping cars, and meals are served in dining cars. Further information may be had from agents of the Baltimore & Ohio Railroad.

The Grand Trunk & Lehigh Valley Route will run special sleepers to Atlantic City, leaving Chicago at 11:05 a. m. Sunday, June 5, and reaching Atlantic City Monday, June 6, at 6:05 p. m. Other trains on this line leave Chicago daily at 3:02 and 8:15 p. m. On the return trip, passengers have the privilege of stop-over at Philadelphia, Niagara Falls and Detroit, for ten days, if desired. The rate from Chicago is the same as stated above.

It is to be noted that all tickets are to be deposited immediately on arrival at Atlantic City with the joint railroad agent, who will certify the ticket and return it to the passenger on the day on which he will leave Atlantic City. This date of leaving is to be not earlier than June 4, nor later than June 13. No deposit fee is required. Any further particulars that may be desired or any explanation concerning matters referred to above may be obtained by applying to the nearest railroad agent. If such agent is not informed of all these details, he will know the proper railroad official to whom to apply.

St. Louis Exposition.

As there will be specially low rates to St. Louis, on account of the Exposition, members from considerable western territory will find it convenient to buy tickets to that city and thence to Atlantic City. We have not yet received particulars of special trains from St. Louis. These will be announced later if they are arranged for.

ORGANIZATION MEETING AT ATLANTIC CITY.

Gathering of Councilors and Officers of State Associations to Discuss Organization.

An important meeting of councilors and presidents and secretaries of state associations and others especially interested in the work of medical organization, has been called in the assembly room of the House of Delegates, at the High School Building at Atlantic City, at 3 p. m., Tuesday, June 7, to consider the practical questions involved in this great movement. Many of the most experienced officers and councilors from every section of the union have signified an intention to attend and to take part in the meeting, and a cordial invitation is extended to all to do so without other notice.

The following provisional program has been arranged, the papers being limited strictly to ten minutes:

1. The Councilor and His Difficulties, Leartus Connor, Detroit, Chairman of the Michigan Council.
2. The Councilor and His Successes, W. B. Russ, San Antonio, Chairman of the Texas Council.
3. How County Societies May Be Made Attractive, Brooks F. Beebe, Cincinnati, Chairman of the Ohio Council.
4. The Qualifications of a State Secretary, Arthur T. McCormack, Bowling Green, Member of the Kentucky Council.

It is expected that these papers will be followed by crisp discussion of the issues presented, each speaker being limited to five minutes. Those present will determine for themselves as to whether or not other meetings will be held during this session, and as to the advisability of making the organization permanent.

OPHTHALMOLOGY PAPERS ILLUSTRATED.

Convenient Device for Illustration of Papers Before the Section on Ophthalmology.

Through the courtesy of the Chicago Eye, Ear, Nose and Throat College, the Section on Ophthalmology will have the use of the Hoy opaque projector—the first model of the instrument so far built—in illustrating papers read at the Atlantic City session. The greatly magnified image of black and white or colored drawings (original or reproduced in atlas, magazine or other book), such as perimeter charts or fundus paintings, can be projected, without previous preparation, on the screen. It is not necessary to remove such pictures from the book or magazine containing them. Instruments, flat bones, or, indeed, any flat object not too large (not over 12 inches in length or breadth), can be faithfully projected in the same way. In addition to this instrument, two stereopticons and an instrument for projecting microscopic slides will be furnished for the convenience of members. Prospective readers of papers should notify the secretary of the section, Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., how many slides, drawings or other illustrations they will present.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending May 14, 1904:

Kean, Jefferson R., surgeon, Webb, Walter D., and Lyster Theo. C., asst.-surgeons, appointed members of a board of medical officers to meet at West Point, N. Y., about May 23, 1904, for examination of cadets of graduating class and candidates for admission to the Academy.

Geddings, Edward F., asst.-surgeon, granted two months' leave about May 15, with permission to apply for one month's extension

Rutherford, Henry H., asst.-surgeon, now on sick leave of absence at Hot Springs, Ark., will report to commanding officer, Army and Navy General Hospital, for such duty as he may be able to perform.

Stedman, Chester J., asst.-surgeon, relieved from duty at Columbus Barracks, Ohio, and ordered to Fort Liscum, Alaska, for duty.

Bartlett, Cosam J., asst.-surgeon, relieved from duty at Fort Liscum, Alaska, and ordered to San Francisco, and on arrival to report by telegraph to the military secretary for further orders.

Bosley, Jno. R., asst.-surgeon, relieved from duty at Fort Thomas, Ky., and ordered with Third Infantry to Fort Egbert, Alaska, for duty.

Clayton, Jere B., relieved from duty at Fort Egbert, Alaska, and ordered to Fort William H. Seward, Alaska, for duty.

Rand, I. W., asst.-surgeon, relieved from duty at Ord Barracks, Cal., and ordered to cantonment, Presidio of San Francisco, for duty.

Bushnell, Geo. E., surgeon, ordered to assume command of general hospital, Fort Bayard, N. M., on departure therefrom of Lieut-Colonel Edward T. Comegys, deputy surgeon general, under orders for duty in the Philippines.

La Garde, Louis A., surgeon, assignment to Philippine Islands revoked and ordered to duty with the Isthmian Canal Commission.

Felts, Robert L., contract surgeon, granted an extension of one month to his leave of absence.

Titus, Frank H., contract surgeon, relieved from duty at the Presidio of San Francisco and ordered to duty at Ord Barracks, Cal

Kierulff, H. Newton, contract surgeon, relieved from duty at the Presidio of San Francisco and ordered to duty at the Infantry Cantonment, Presidio of San Francisco.

Ames, Roger P., contract surgeon, granted an extension of five days to his leave of absence from Fort McIntosh, Texas.

Chase, Alpha M., contract surgeon, granted three months' leave of absence from Fort Reno, Okla.

McMillan, Clemens W., contract surgeon, ordered from temporary duty at Fort Ethan Allen, Vt., to Fort Niagara, N. Y., for temporary duty during the target practice season; to return thence to his proper station, Fort Myer, Va.

Navy Changes.

Changes in the Medical corps of the Navy, week ended May 14:

Spratling, L. W., surgeon, detached from duty with the Marine Battalion on the Isthmus of Panama and ordered to duty with the Panama Canal Commission.

Rodman, S. S., P. A. surgeon, commissioned a P. A. surgeon with rank of lieutenant from Dec. 14, 1903.

Sutton, R. L., asst.-surgeon, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to duty with the Marine Battalion on the Isthmus of Panama.

Ledbetter, R. E., asst.-surgeon, ordered to the *Lancaster*.

Braisted, W. C., surgeon, detached from the Naval Hospital, New York, and ordered to the *Relief;* authorized to delay one week en route.

Miller, Jr., J., asst.-surgeon, detached from the Naval Museum of Hygiene and Medical School and ordered to the *Denver*.

Zalesky, W. J., asst.-surgeon, ordered to the Naval Hospital, Philadelphia.

Norton, O. D., surgeon, detached from the Navy Yard, League Island, Pa., and ordered to the *Illinois*.

Gates, M. F., surgeon, detached from the Naval Hospital, Philadelphia, and ordered to the Navy Yard, League Island, Pa.

Blackwood, N. J., surgeon, detached from the *Illinois* and ordered to the Torpedo Station, Newport, R. I., with additional duty in attendance on navy and marine officers not otherwise provided with medical aid at Newport, R. I.

Wilson, G. B., surgeon, detached from the Torpedo Station, Newport, R. I., and ordered to the Naval Hospital, Chelsea, Mass.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine Hospital Service, for the seven days ended May 12, 1904.

Carrington, P. M., surgeon, detailed to represent the Service at meeting of the American Medical Association, June 7, 1904, stopping en route at the Bureau.

Nydegger, J. A., P. A. surgeon, granted extension of leave of absence on account of sickness for one month from April 6.

Sprague, E. K., P. A. surgeon, relieved from duty at Calcutta, India, and directed to proceed to the United States.

Kerr, J. W., P. A. surgeon, granted leave of absence for one month from May 20.

Goldberger, Joseph, asst-surgeon, relieved from duty at Tampico, Mexico, and directed to proceed to Monterey, Mexico, for duty.

Holt, J. M., asst.-surgeon, Bureau letter of Feb. 9, 1904, directing him to report to P. A. Surgeon V. G. Heiser at Manila, P. I., for examination for promotion, revoked.

Burkhalter, J. T., asst.-surgeon, granted extension of leave of absence for ten days.

Wightman, W. M., asst-surgeon, granted leave of absence for seven days from May 1, 1904, under Paragraph 191 of the Regulations.

McKeon, F. H., asst.-surgeon, to proceed to New York (Stapleton) and report to medical officer in command for duty and assignment to quarters.

Pettyjohn, Joseph, and Sweet, E. A., asst.-surgeons, to proceed to New York and report to Surgeon G. W. Stoner, Immigration Depot, for duty.

Spratt, R. D., asst.-surgeon, to proceed to New Orleans and report to medical officer in command for duty and assignment to quarters.

Alexander, E., A. A. surgeon, leave of absence for ten days from May 1, 1904, letter of April 26, revoked.

Richardson, N. D., A. A. surgeon, granted leave of absence for seven days from Feb. 25, 1904, under Paragraph 210 of the Regulations.

Slaughter, A. W., A. A. surgeon, granted leave of absence for 14 days from June 1.

Comfort, N. C., pharmacist, reassigned to duty at Manila, P. I., effective February 7.

Neves, George, pharmacist, directed to proceed to Cairo, Ill., and report to medical officer in command for temporary duty during the absence on leave of Pharmacist C. G. Carlton.

Siedenburg, Frank, pharmacist, to proceed to San Francisco and report to medical officer in command for duty and assignment to quarters.

APPOINTMENTS.

McKeon, F. H., of Connecticut; Pettyjohn, J., of Georgia; Sweet, E. A., of Massachusetts, and Spratt, R. D., of Alabama, commissioned as assistant surgeons.

REINSTATEMENT.

Siedenburg, Frank, of Illinois, reinstated as pharmacist of the third class May 3, 1904.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended May 14, 1904:

SMALLPOX—UNITED STATES.

Florida: Jacksonville, April 30-May 7, 4 cases.

Illinois: Chicago, April 30-May 7, 2 cases.

Kentucky: Covington, April 30-May 7, 5 cases.

Louisiana: New Orleans, April 30-May 7, 5 cases.

Maryland: Baltimore, April 30 May 7, 5 cases.

Michigan: April 30 May 7, Detroit, 1 case; Grand Rapids, 3 cases.

Missouri: St. Louis, April 25-May 7, 35 cases.

New Hampshire: Manchester, April 30-May 7, 2 cases.

New Jersey: Camden, April 30 May 7, 1 case.

New York: April 30-May 7, Buffalo, 3 cases; New York, 1 case.

Ohio: April 30-May 7, Bucyrus, 3 cases; Dayton, 12 cases, 1 death; Toledo, 1 case; April 29-May 6, Cincinnati, 15 cases, 1 death; Cleveland, 4 cases.

Pennsylvania: April 30-May 7, Philadelphia, 26 cases, 5 deaths: Pittsburg, 6 cases, 1 imported.

South Carolina: Charleston, April 30-May 7, 2 cases; Greenville, April 23-30, 9 cases.

Tennessee: Nashville, April 30-May 7, 8 cases.

Wisconsin: Milwaukee, April 23-May 7; 4 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, March 12-26, 9 cases, 1 death.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Feb. 1-29, 51 deaths.

Austria: Prague, April 16-23, 2 cases.

Belgium: Antwerp, April 16-23, 16 cases, 6 deaths.

Brazil: Rio de Janeiro, March 27-April 10, 95 cases, 63 deaths.

Canada: Sydney, to April 30, 55 cases, 1 death; Winnipeg, April 23 30, 1 case.

China: Shanghai, March 26-April 2, 15 deaths.

Colombia: Barranquilla, April 18-24, 1 death.

Great Britain: April 16-23, Dundee, 2 cases; Edinburgh, 2 cases; Hull, 3 cases; Glasgow, April 22-29, 31 cases, 2 deaths; Leeds, April 23-30, 5 cases.

Russia: Odessa, March 26-April 23, 9 cases, 1 death; St. Petersburg, April 8-16, 12 cases, 3 deaths.

Turkey: Alexandretta, April 8-16, 16 cases, 1 death; Constantinople, April 10-24, 11 deaths; Smyrna, March 26-April 3, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, March 26-April 10, 8 cases, 4 deaths.

Ecuador: Guayaquil, April 9-16, 8 deaths.

Mexico: Merida, April 24-30, 2 cases, 1 death.

CHOLERA.

India: Calcutta, April 2-9, 104 deaths; Madras, April 2-8, 8 deaths.

PLAGUE—INSULAR.

Hawaii, Honolulu, May 8, 1 death.

Philippine Islands: Manila, March 12-26, 8 cases, 8 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, April 3-10, 3 cases.

India: Calcutta, April 2-9, 539 deaths: Bombay, April 5-12, 811 deaths.

Peru: Callao, April 3-10, 1 case, 1 death; Chosica, April 14, 2 deaths; Matacuna, April 14, 2 cases.

Medical Organization.

Illinois.

Iroquois-Ford County Medical Society.—This society was organized at Gilman, May 13, on the standard plan, by Dr. Otto B. Will, Peoria, councilor for the Fourth District, with thirty-six charter members. The following officers were elected: President, Dr. Daniel L. Jewell, Watseka; secretary, Dr. Arthur W. White, Paxton; treasurer, Dr. Frank B. Lovell, Gibson City; censors, Drs. Tolbert B. Strauss, Gibson City, Amos J. Newell, Onarga, and John D. Tieken, Piper City, and delegate to the state society, Dr. Samuel D. Culbertson, Piper City.

Iowa.

Cedar County Medical Society.—This society was reorganized at Tipton, May 10, on the standard plan; the constitution and by-laws recommended by the American Medical Association were adopted, and the following officers reinstated: Dr. Charles W. Baker, Stanwood, president; Dr. Roscoe A. Nash, Tipton, secretary, and Dr. Louis J. Leech, West Branch, treasurer. Dr. Edward J. Van Metre, Tipton, was elected delegate to the state society, and Dr. Charles W. Baker, Stanwood, alternate.

Ohio.

Paulding County Medical Society.—Physicians of Paulding County met at Paulding, May 4, effected organization on the standard plan, and elected the following officers: Dr. L. R. Fast, Paulding, president; Dr. George M. Brattain, Antwerp, vice-president; Dr. Ira J. Dix, Paulding, secretary; Dr. John H. Hosford, Paulding, treasurer; Drs. George E. Brattain and Edwin A. Clark, Paulding, and Dr. Ambrose H. Mouser, Latty, censors, and Dr. George M. Brattain, Antwerp, delegate to the state association.

Reorganization of Oklahoma.

The Oklahoma State Medical Association met at Oklahoma City May 11. As the first order of business a special committee was appointed to consider and report on the subject of a reorganization of the association along the lines proposed by the American Medical Association. At the first afternoon session this committee reported and recommended that the rules be suspended and that the standard constitution and by-laws be adopted by unanimous consent, and this was done with much enthusiasm. This action resulted largely from the phenomenal work done in Texas during the past year, the connection between the profession of the two jurisdictions being very intimate. The officers elected for the coming year were as follows: President, Dr. Aarcha K. West, Oklahoma City; vice-president, Dr. Richard H. Tullis, Lawton; secretary-treasurer, Dr. Eugene

O. Barker, Guthrie; councilors, Drs. Abraham I. Blesh, chairman, Guthrie, William E. Dicken, Oklahoma City, Mahlon A. Kelso, Enid, Richard H. Tullis, Lawton, and Ira B. Bartle, Augusta. There are twenty-six counties in Oklahoma, each of them having a sufficient number of physicians to form a strong local society. In several instances, county societies have already been organized in anticipation of the action of the parent association. As the rank and file of the profession is made up of aggressive and progressive young men excellent results may be looked for as the result of the reorganization.

Texas.

Fourth Councilor District.—Dr. Vernon Mac Cammon, councilor for the Fourth District, writes that the eight counties forming his district all report an increase of membership, and that six out of eight have all the eligible men in the county as members. General satisfaction is expressed by all in regard to the new plan of organization, and the results the profession of the state have already derived from it. He says that in several instances members of the legislature have come before the county society and asked what the members wanted them to do.

An Epoch in Texas History.—The editor of the *Texas Medical Journal*, announcing the meeting of the Texas State Medical Association, said that the session would mark an epoch in the history of the association, and commented further as follows:

> Indeed, that organization is now, for the first time, a state medical association in fact, as well as in name. There was something radically wrong in the old organization, as it was found impossible, after twenty or thirty years of zealous and persistent effort, to effect union and cohesion, and the active membership ranged from three to four hundred only. Under the reorganization, which makes organization of county medical societies and membership in the same essential to membership in the state and national associations, and constitutes said county societies an integral part of the state association, the membership has run up within a year to something like 2,500. We assemble this month for the first time since the reorganization. The day is near when to not be a member will make one unpleasantly conspicuous. This renewed interest and awakening of the medical profession has attracted the public attention, and looking to this great association of physicians and sanitarians for guidance and advice in the matter of protection of the public health, the people will, I think, actively aid and support its laudable efforts in that direction. Indeed, I have been assured by representative men and leading members of both houses of the legislature that when the state medical association agrees on any measure needed for the protection of the public health and asks for it, it will be enacted.

Organization in Texas—The Good Work of the Councilors.—To show what has been done in one state we abstract the following from the report of Dr. W. B. Russ, San Antonio, chairman of the board of councilors, made to the House of Delegates of the State Medical Association of Texas:

> Before presenting a résumé of the results obtained by our efforts I beg to direct your attention to some of the difficulties with which we have had to contend.
>
> To begin with, not a member of the council had ever had any personal experience with organization work along the lines prescribed by the American Medical Association reorganization plan, and, being for the most part busy men, many of them found it an exceedingly difficult matter to arrange their affairs so as to be able to make their official visits at the proper time to neighboring counties. To add to this difficulty the engagements for these visits had to be made a number of days in advance, and could not be broken under any circumstances without serious injury to the progress of the work in the territory under process of organization.
>
> Again, a vast majority of the physicians in almost every county had never been connected with any medical organization whatever, and most of those who had at some time attempted to organize a local society and to keep it alive had been discouraged by failure. Practically all except the councilors themselves were entirely unfamiliar with the new plan of organization, and for this reason but few at first could be induced to give the matter even serious attention. Petty jealousies and bitter feuds between individuals in small communities, and between factions in large towns, were encountered on every hand. Lack of transportation facilities, the loss of time and the expense incurred in attending meetings and similar considerations made many men of reputation and influence hesitate to join. Every conceivable reason from press of business to general lack of interest has seemed to operate in some localities to keep eligible men from taking a proper interest in the work. But in most instances the councilors have found themselves able to meet the emergencies of the occasion. Referring to the difficulties encountered in his district (a fair example of those met elsewhere), and to the method he has employed in dealing with the same, Dr. Holman Taylor writes:
>
> "Perhaps the greatest obstacle met with is the indifference of the profession generally, and the difficulty of getting at them. I have met this by always selecting a good worker in the largest town in the county, getting him enthused, fully instruct him, then put him to work on the rest of them, finally calling a meeting when interest seems to be aroused sufficiently to make it a go. I have never found it very difficult to talk the crowd into organizing at once; the only difficulty is to get the crowd."
>
> The results during the past nine or ten months of active work of the board of councilors in prosecuting this great undertaking, amply testify to the zeal and enthusiasm displayed by a majority of the board, but in this connection I cannot refrain from referring to the hard work done and sacrifice of time entailed by some of the individual members of the board. In reply to an inquiry as to the time consumed in the discharge of his duties as councilor, Dr. Sam R. Burroughs of the eleventh district writes:
>
> "The time required to cover an almost continuous correspondence, including the preparation and mailing of circular letters and other literature, with the addition of one visit to each of nine counties, and two visits to two counties, could very likely be compressed into two months, but the loss of this time in the manner in which it has actually occurred has operated to a greater loss of time to the councilor."
>
> Dr. Cantrell of the fourteenth district reports: "I have spent about forty days away from home on organization work during the past year, during which time I have visited nineteen counties."
>
> Drs. Fly of the third district and Alexander of the fourth district and Calhoun of the tenth district have lost from twelve to sixteen days each from their practice, and most of the others have suffered fully as much loss. These figures do not include the time devoted to keeping up with the enormous amount of correspondence, which in many instances has been practically continuous during a greater part of the entire year.
>
> Briefly stated, the results obtained are as follows:
>
> Total number of counties organized during year ending April 26, 1904, 175.
>
> Number of county societies established, 129.
>
> Total number of eligible physicians in state (estimated), 4,700.
>
> Present membership of county (and state) organizations, 2,510.
>
> Number of eligible physicians not yet connected with organization, 2,190.
>
> Membership of State Association in April, 1903, 368.
>
> Increase in membership during year ending April 26, 1904, 2,142.
>
> Per cent. increase during year ending April 24, 1904, 582+.
>
> One year ago we estimated that we would be able to increase the membership to 1,000. Six months ago we estimated that the increase would reach 1,500. Three months ago we hoped it might reach 2,000. We were, therefore, surprised to find that the total enrollment reached over 2,500. The increase in interest in the work and the increase in the enthusiasm with which the county society officers have taken it up is but little short of amazing.
>
> Much has been accomplished, but much yet remains to be accomplished. We have devoted our time during the first year to the work of establishing organizations in as many counties as possible. To our successors will be given the task of keeping alive and adding strength to the societies already in existence, as well as that of multiplying the number of organizations. The success or failure of their efforts will depend largely on the spirit and manner in which the county organizations receive their advice and meet their efforts at assistance. It is not to be expected that every member of every society will become an active and enthusiastic worker; nor will the success and prosperity of the society depend upon the attainment of this much-to-be-desired but never-to-be-realized result. Fortunately the efforts of even one active and tactful man in a given county may easily be the means of building up a strong and enduring organization. If the delegate, for example, whom it is presumed is at least one of the best informed men in his home county as to the merits of our present organization plan, will use his influence to make sure that the secretary and other officers and committees are frequently reminded of their official duties and responsibilities, more than one-half of the burden of the work will be lifted from the shoulders of the councilors, and the results for good will be immediately apparent, and, needless to say, most gratifying.
>
> The future success of the county society will of course depend on the efficiency of its officers and committees; consequently we can not too strongly condemn the tendency now manifested in some counties to regard the matter of election to office in the light of an honor to be given as a tribute of respect rather than as a trust to be placed in the hands of active and energetic men.
>
> This report would not be complete without some reference to the invaluable advice and assistance received on many occasions from Dr. J. N. McCormack, Chairman of the A. M. A. Committee on Reorganization. The medical profession of Texas, as well as that in many other states, owes to Dr. McCormack and his associates a debt of gratitude which cannot be overestimated.

Society Proceedings.

COMING MEETINGS.

American Medical Association, Atlantic City, N. J., June 7-10.

American Gynecological Society, Boston, Mass., May 24.
Medical Society of the State of North Carolina, Raleigh, May 24.
North Dakota State Medical Society, Fargo, May 25-26.
Connecticut Medical Society, New Haven, May 25-26.
Michigan State Medical Society, Grand Rapids, May 25-27.
American Medico Psychological Assn., St. Louis, May 30-June 3
Amer. Laryn., Rhin., and Otol. Society, Chicago, May 30-June 2
South Dakota State Medical Association, Redfield, June 1-2.
Maine Medical Association, Portland, June 1-3.
International Assn. of Railway Surgeons, Chicago, June 1-3.
Minnesota State Medical Society, Minneapolis, June 2-3.
American Therapeutic Society, New York City, June 2-4.
American Dermatological Association, Niagara Falls, June 2-4.
Rhode Island Medical Society, Providence, June 3.
Conf. of State and Prov. Bds. of Health of N. A., Wash., June 3-4.
Indian Territory Medical Association, Holdenville, June 3-5.
American Academy of Medicine, Atlantic City, June 4-6.
Medical Society of New Jersey, Atlantic City, June 4-7.
Nat. Conf. State Med. Exam. and Lic. Bds., Atlantic City, June 6.
American Medical Editors' Association, Atlantic City, June 6.
American Assn. Life Ins. Exam. Surgs., Atlantic City, June 6.
American Gastro-Enterological Association, Atlantic City, June 6.
Nat. Assn. of U. S. Pen. Exam. Surgs., Atlantic City, June 6-7.
Association of American Medical Colleges, Atlantic City, June 6.
Massachusetts Medical Society, Boston, June 7-8.

American Orthopedic Association, Atlantic City, June 8-10.
American Urological Association, Atlantic City, June 10-11.
Medical Society of Delaware, Lewes, June 14.
Wisconsin State Medical Society, Milwaukee, June 22.

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held April 14, 1904.

The President, Dr. Samuel Wolfe, in the Chair.

Some Reflex Conditions Caused by Foreign Bodies in the Intestinal Tract.

Dr. Anna M. Reynolds read this paper. The first case was that of an infant six months old, taken suddenly ill in the morning with diarrhea followed by vomiting, which was diagnosed on the fourth day as caused by the uterus pressing on the bowel. The next day several hard convulsions occurred, resulting fatally, and the condition was found to be impaction of the bowel.

Another case which was diagnosed as extra-uterine pregnancy proved to be a mass of blackberry seeds. In another, a male infant, had "bilious attacks" which increased in frequency, and finally he lost consciousness; the case was diagnosed as epilepsy. On administration of half a grain of calomel every hour for six doses, followed by castor oil, he passed a brass button which he had lost off his coat, and the convulsions ceased.

Another case was that of a young man who had convulsions at the age of three years and at twenty-four developed epilepsy. He was treated by the bromids with no success, after which he went to the country and gave careful attention to his diet and bowels, and has had only two very light seizures in four months.

DISCUSSION.

Dr. Boardman Reed believed that there was a great many more conditions resulting from reflex symptoms of the intestinal tract than is usually recognized, not only epilepsy, but also headaches, nervousness, etc., and that even true epilepsy was much aggravated by disturbance therein; he recommended thorough daily evacuation of the bowels.

Dr. William H. Good referred to the case of a woman who was troubled with hoarseness, which disappeared after the expulsion of a large amount of worms.

Dr. Frank White referred to two cases as illustrating the tolerance of the intestinal tract without producing reflex symptoms in some cases. In the first a foreign body 5½ inches long by 1½ inches in thickness and weighing four and one-half ounces was removed from the stomach of an idiotic boy at autopsy; and in the other case about 15 whole shellbarks and about half as many in pieces were removed from a boy's rectum. In neither case were there any reflex symptoms.

The Surgical Treatment of Abortion.

Dr. Frank C. Hammond read a paper in which he stated that it was always desirable to ascertain when threatened abortion becomes inevitable, as the treatment will be thereby radically altered. He called attention to the fact that hemorrhage more or less persistent might exist, even during the entire period of pregnancy, without producing an abortion. He cited the cases observed by Playfair, Charpentier, Doloris and others, in which pieces of decidua were expelled without the interruption of pregnancy. When the abortion is inevitable, the chief dangers are from hemorrhage, general septicemia or local infection. Tetanus occasionally follows abortion. Suspicion should always be directed to a case resembling acute articular rheumatism, following a recent abortion, as it is much more likely to be suppurative arthritis, which should be treated by free incision and drainage, strict antisepsis being observed.

The remote dangers from abortion are inflammatory disease of the uterus and adnexa, with the resultant train of pelvic and reflex symptoms. He reported a case in which two Italian physicians had diagnosed malignant uterine disease in a woman of 50, in which curettage and packing with iodoform gauze proved the case to be one of incomplete abortion with retained putrefactive débris. The author believed that if every case of inevitable abortion was submitted to an antiseptic curettage properly done, the mortality would be nil, except in criminal abortions. He believed that the expectant plan of treatment will produce the best results in the hands of the general practitioner, so long as fever, excessive hemorrhage and putrefaction are absent; any retained débris should be removed, for even though it does not produce fever or sloughing, it may cause inflammatory disease of the pelvic organs and invalidism. The author referred to a case on which he operated for bilateral laceration of the cervix and lacerated pelvic floor, no disease of the adnexa, in which the uterus was literally filled with débris, the woman admitting to over 20 self-induced abortions. When abortion is inevitable, the uterus should be at once thoroughly emptied under anesthesia. The treatment of sapremia following abortion should be by emptying the uterus and thorough disinfection of the genital tract with intrauterine douches of formalin 1 to 1,500; or sublimate solution 1 to 3,000 or to 4,000, followed by normal salt solution to avoid the danger of mercuric poisoning. The treatment of septicemia depends on the character of the infection and may be either by measures tending to neutralize the bacteria, or surgical by the evacuation of pus or the removal of the diseased organs.

Difficulty of differential diagnosis is experienced when typhoid makes its first appearance at childbirth. Intravenous injections of normal salt solution, quinin, strychnin, digitalis and atropin, as indications arise; and careful regulation of the diet should be enforced, and in severe cases collapse may be overcome by ammonium carbonate per rectum and nitroglycerin hypodermatically. The treatment of septicemia due to streptococci should be by means of antiseptic uterine douches and drainage by loosely packed iodoform gauze; curettage should not be employed owing to its likelihood of spreading the germs and the production of general infection in an already localized case. Pryor advocates the isolation of the infected uterus between masses of iodoform gauze and local and systemic iodism, to destroy the cocci, locally and systemically. Pus tubes and ovarian abscesses should be removed, either per vagina or by abdominal incision, depending on the accessibility of the lesion and the condition of the patient.

The Etiology and Medical Treatment of Abortion.

Dr. I. P. Strittmatter stated that the most frequent causes of abortion in his experience had been as follows: 1, prior criminal abortion; 2, syphilis; 3, pyosalpinx; 4, backward displacement of the uterus. In the first class of cases, careful curettage and packing and general tonic treatment; in the second class of cases, administration of the iodids and general antisyphilitic treatment, and in the fourth class suitable operation, had given the best results. In those cases in which there is a relaxed condition of the muscles and joints, with frequent attacks of rheumatism and sometimes attended by heart lesions, antirheumatic treatment should be instituted.

The Medicolegal Aspects of Criminal Abortion.

Thomas W. Barlow of the Philadelphia Bar referred to the difference in the laws of different states on this subject, and called attention to the fact that the law of Pennsylvania applies to an abortion committed at any time during pregnancy, while in most other states it must be done when the woman is "quick" with child. He believed that the laws of Pennsylvania were sufficient in this respect and that if the crime was increasing it was due to the non-execution thereof by those on whom the obligation rests. He referred to the function of the police department, detective department, magistrates, coroner, district attorney and courts in the prosecution of such crime, and stated that it was impossible that all should be accomplished by the police power, and suggested that the work against the professional abortionist rests entirely within the profession itself. He recommended that a committee be appointed to take charge of the matter; he believed this would have a deterrent effect on such lawbreakers.

Discussion on the Attitude of the Physician in Cases of Criminal Abortion.

Dr. Richard C. Norris stated that while he appreciated the sentiment that prompted Mr. Barlow's suggestions, he felt that there were certain practical difficulties in the way, the chief of which was the *confidential relation* that existed between physician and patient, which deters the physician from reporting the case to the authorities. Another difficulty is the shrewdness with which the abortionists do their work, making it almost impossible to secure legal evidence against them. Many of them even subject their patients to an oath, so that in numerous cases, even with a knowledge of impending death, the victims will not reveal the author of the crime, owing to the sanctity of the oath. He believes that the appointment of a committee might have a deterrent effect on a certain class but that the most good could be accomplished by the medical profession by teaching their patients the moral wrong of the affair.

Dr. A. M. Eaton urged that the physician impress on any patient who should request him to perform an abortion the moral turpitude of the crime, and referred to three cases, in which the women had desired to have the act committed, who had been deterred therefrom by his suggestion to go to a secluded part of the city until after the birth of the child. He referred to the case of a barber who stated that he had performed over 250 abortions without any fatalities by taking a soft catheter and inserting in the womb and injecting milk and carbolic acid "until something gave way."

Dr. Mordecai Price stated that he never treated a case of abortion until he was informed who had performed the operation, which course he deemed necessary for the safety of the attending physician. In any case in which the fetus is dead, he believed that it should be removed at once, and when either the membranes or the fetus are discovered to be coming away, the uterus should at once be emptied, with the hand, the curette being used only in cases of necessity. He did not sanction irrigation of the uterus with any fluid and particularly deprecated bichlorid of mercury douche.

Dr. A. C. Morgan referred to a case in which he felt that his professional relation would have prevented him from giving evidence to convict the abortionist, and this he agreed with Dr. Norris was the practical difficulty in the way of the conviction of these men.

Dr. W. E. Parke raised the question as to whether the physician should report a case when he is called in or should the whole thing be kept quiet. He referred to a case which he had seen, in which there had been bleeding and straining for 24 hours, and although the patient absolutely denied any action to induce abortion, it was evident that such was going on. No urine had been passed since the beginning of the attack, and catheterization yielded about a dram of almost pure blood, which could not be accounted for. A few hours later the uterus was cleaned out and three hours thereafter, catheterization yielded about a dram of a slightly less bloody fluid. The next morning it was discovered that there was an opening from the bladder into the genital tract. The patient apparently improved; the temperature became normal and the pulse nearly so for about two weeks, when she was taken suddenly worse and died. The conclusion was reached that the fistula in the genital tract was produced by pushing something into the bladder through the vagina or cervix, in an attempt to produce an abortion.

Dr. Henry S. Cattell recommended that a blacklist be kept by a committee of the county medical society of all the physicians and others who are suspected of doing this work, which should only be accessible to such committeee, and believed that many physicians would give information to such a committee with the understanding that it would not be given publicity, that they would not give otherwise. He stated that he made attempts, by communicating with the postoffice authorities at Washington, to have the mail of certain of such practitioners withheld, but he had been informed that there was not sufficient evidence to warrant this course.

Dr. Frank C. Hammond said that the untoward effects produced by the use of the curette were rather the fault of the operator than of the instrument. He stated that he could see no reason for objecting to free irrigation of the uterus, as any infected wound should be treated by irrigation and drainage; if bichlorid of mercury douche is used it should be followed up by normal salt solution in order to prevent mercurial poisoning.

Thomas W. Barlow urged on the audience their duty to report every case of crime of which they had knowledge, but whether the relations with the patient were such as to deter such action he felt must be decided by the physician in the individual case. He also dwelt on the importance of the coroner's office and the necessity for the continuance thereof.

ASSOCIATION OF AMERICAN PHYSICIANS.

Nineteenth Annual Meeting, held at Washington, D. C., May 10 and 11, 1904.

The President, Dr. W. T. Councilman, in the Chair.

President's Address.

Dr. William T. Councilman, Boston, in his address as president, announced the death of Israel M. Dana, Portland, Maine, and paid a tribute to his memory. He then referred to the history of the association, recalling to the minds of the members the fact that during the nineteen years of its existence many papers had been presented which had added materially to the stock of the world's knowledge.

The following committee was appointed to co-operate with the trustees of the Reed Memorial Fund: Edward G. Janeway, New York; William H. Welch, Baltimore, and Frank Billings, Chicago.

The Influence of Suprarenal Extract on Absorption and Elimination.

Drs. S. J. Meltzer and John Auer, New York City, read this paper. The first experiments were made on frogs, in which animals it was found that by the addition of suprarenal extract the tetanic influence of strychnin can be avoided entirely or delayed for one or two hours. This delay and reduction of the symptoms is not in the nature of a chemic reaction, but rather appears to be of a biologic nature. If adrenalin be injected into a frog, the animal becomes paralyzed, which is of a central nature and is not muscular in character. The same phenomenon has been observed in mammals and is explained by delayed absorption. After injecting fluorescin into a rabbit the conjunctivæ, mucous membranes and skin become yellow in from fifteen to twenty minutes. If adrenalin is injected before the fluorescin this reaction is delayed. After the injection of fluorescin the blood serum becomes fluorescent immediately; the injection of adrenalin delays the absorption of the former substance into the blood. Experiments have also shown that adrenalin also delays elimination. This delay of elimination is true, at least, in relation to the kidneys. Possibly in certain cases the use of adrenalin may be found to delay the absorption of toxic materials, for example, diphtheria. It may be found possible to delay elimination when necessary.

DISCUSSION.

Dr. W. Gilman Thompson, New York City, said that he had only used adrenalin by intravenous injection in addition to normal salt solution, but that he had never seen any effect on the appearance or composition of the urine follow.

Dr. Hobart A. Hare, Philadelphia, said that the duration of the action of adrenalin is very brief and unless given repeatedly he does not see how the effect described by Meltzer can be produced. He has been impressed with the fact that the local application of adrenalin increases the absorption of infectious materials and he believes that its local application in diphtheria would be dangerous. Meltzer said that the effect of adrenalin on the pupil, after removal of the superior cervical ganglion of the sympathetic system, lasts for three or four hours. If the cervical sympathetic be cut the influence of adrenalin on the blood vessels of the ear is not transitory. The influence of adrenalin on non-striated muscle is prolonged.

Polyuria in Typhoid Fever.

Drs. M. Howard Fussell, H. S. Carmany and H. Hudson, Philadelphia, read this paper. A man, aged 40 years, was first seen on the eighth day of the disease. He was extremely nervous all during the course of the disease and had one slight intestinal hemorrhage. He was bathed at 103 degrees, but was not tubbed. On admission he was passing 1,200 c.c. urine, but on the fourth day after admission he passed 7,000 c.c., and the next day he passed 7,200 c.c. The excretion then fell to 3,000 c.c. and gradually fell to normal during the subsequent course of the disease, but did not reach 1,500 c.c. until convalescence was well established. The urine contained neither albumin nor glucose. At one time salicylic acid was found after the administration of salol. There was no acetone; there was about a normal urea excretion. The patient was seen one year after the attack of typhoid fever, when his urine was found normal in quantity and character. It is usual to find slight polyuria during convalescence from typhoid fever, as pointed out by Murchison and by Osler. Fussell has noted polyuria during convalescence from typhoid fever in only 8 per cent. of his own cases. Exceptionally polyuria has been noted during the entire course of the disease.

DISCUSSION.

Dr. George Dock, Ann Arbor, Mich., said that there appears to be a retention of fluid in the body followed by polyuria. A temporary decline in the temperature seems to be followed by an increase in the amount of urine. It appears that it is possible to wash out the system with water in febrile conditions.

Dr. W. Gilman Thompson, New York City, asked whether the patient was emaciated and whether he had had a previous attack of polyuria.

Dr. William Osler, Baltimore, said that polyuria is sometimes associated with local abdominal lesions such as tuberculous peritonitis.

Dr. William S. Thayer, Baltimore, said that Cushing allows his patients to have very large quantities of water and that they pass large quantities of urine. They seem to do extremely well.

Dr. Fussell said that no observation had been made on the blood pressure of his patient. It appeared to him that the increased ingestion of water appeared to be due to the polyuria rather than that the contrary is true. The patient was not markedly emaciated. It is not known whether he had a previous attack of polyuria; he has not had one since. The patient was less nervous when he was passing 4,000 c.c. of urine than when he was passing 7,000 c.c. There seemed to be no other connection between the nervousness and the polyuria.

Cases of Venous Thrombosis in the Course of Typhoid Fever.

Dr. William S. Thayer, Baltimore, said that out of 4,063 cases of typhoid fever there were 39 cases of venous thrombosis and 2 cases admitted to the hospital during convalescence. Five of the cases were fatal; in one there was pulmonary embolism and in another embolism of the inferior vena cava and the right auricle. In 3 of the cases the formation of the thrombus was attended with no fever; in the other 36 cases there was a febrile reaction. In 11 cases, 28.2 per cent., chills were an accompaniment of the beginning of the condition. The first symptom was pain, which varied in intensity. When the femoral vein was the seat of the thrombus the pain was felt in the line of the femoral vessels, in Scarpa's triangle, in the popliteal region or in the calf. Sometimes the pain was sudden and there were also swelling, redness and edema in some of the cases. In 54 per cent. of the cases there was a leucocytosis, the highest recorded figure being 24,864, in a case of iliac thrombosis. The lowest leucocyte count was 2,700 in a case of popliteal thrombosis without fever. In the majority of cases the thrombosis developed during the third week, when the leucocytes should be about 5,500. In one instance the bacillus typhosus was obtained in pure culture from the thrombus. Of 16 patients communicated with after convalescence it appears that there is a more or less permanent disability in all cases. Marked varicosities of the veins of the hypogastrium follow femoral thrombosis. A sudden, severe pain in the lower part of the adbdomen with leucocytosis is indicative of iliac thrombosis.

DISCUSSION.

Dr. George L. Peabody, New York City, referred to a paper from the Army Medical School at Netley in which the occurrence of femoral thrombosis is said to be due to an increase of calcium salts in the blood, possibly brought about by the large amount of milk given during typhoid fever. It is suggested that the addition of a soluble citrate to the milk may lessen the tendency to coagulation of the blood in a person on such a diet.

Dr. Alfred Stengel, Philadelphia, referred to two cases of thrombosis of the pulmonary artery. Both cases were thought to be primary. He has noted general symptoms in a number of cases before the appearance of local symptoms.

Dr. William H. Welch, Baltimore, said that these cases are probably instances of primary phlebitis from an infection of the walls of the vein with the bacillus typhosus. The organism has been isolated from 70 per cent. of cases of one series.

Dr. Morton Prince, Boston, referred to a case in which phlebitis developed before the symptoms of typhoid fever.

Dr. Charles Carey, Buffalo, said that in his experience the majority of patients recovered entirely.

Dr. W. G. Thompson, New York City, said that of eight cases watched from six to ten years, no patient completely recovered. The pulse rate was increased during the formation of the thrombus, which he believes is influenced by the force of the circulation.

Dr. James Tyson, Philadelphia, said that in these cases he believes the vascular obstruction is the cause of the pain. He likened it to the pain of angina pectoris and the pain of cramp, which may also be due to vascular obstruction.

Dr. William Osler, Baltimore, said that there is a difference between the thrombosis of typhoid fever and phlegmasia alba dolens. The condition seems to be less acute in the former condition. He thinks there are a number of cases in which recovery is complete without varicosities. The ultimate result depends on the anatomic characters of the venous system in the affected region.

Dr. Thayer said that among the general symptoms which indicate the occurrence of true phlebitis he had analyzed the relation between pulse rate and temperature in only one case, one of iliac thrombosis. In this the pulse rate was disproportionate. One patient shows intermittent claudication two years after recovery.

Clinical Studies in Arteriosclerosis.

Dr. Alfred Stengel, Philadelphia, read a paper dealing with cases which do not belong in the senile group and which he calls the pathologic group. The observations were made with the instrument designed by Stanton, which gives systolic and diastolic pressures. In arteriosclerosis the systolic pressure is not always high; but the diastolic pressure, on the other hand, is always high until the myocardium has failed. The sustention of the mean pressure is due to the fact that there is sufficient elastic tissue between the atheromatous areas in the aorta to sustain the pressure in spite of the peripheral resistance. There are no great changes in the blood of these patients notwithstanding the apparent severe anemia; the erythrocytes are high, the hemoglobin is high and the leucocytes are high. This is due probably to the contraction of the peripheral vessels, showing that the process begins in those vessels. The urine is variable in quantity and appears to be independent of the quantity of fluid taken; a fact that may be accounted for by involvement of the glomeruli. The specific gravity also varies considerably, as does the occurrence of albumin and casts. Corresponding with the sustained diastolic pressure there is a sustained, prolonged character of the systolic sound before the myocardial change appears, which is important in diagnosis.

DISCUSSION.

Dr. Francis P. Kinnicutt, New York City, said that the blood pressure in senile arteriosclerosis is lower than in pathologic arteriosclerosis.

Dr. Solomon Solis-Cohen, Philadelphia, said that the character of the wall of the vessels, the changes in innervation and the change in the force of the blood can not be recorded by an instrument. Arterial tension and blood pressure are not synonymous. He lays great stress on the prolongation and the impunity of the first sound of the heart without definite murmur. The urine also shows a tendency to diminution of the excreted nitrogenous toxic materials.

Effects of Cardiac Stimulants, Especially Strychnin, on the Blood Pressure in Febrile Conditions.

Dr. Richard C. Cabot, Boston, employed the Stanton instrument for recording the blood pressure after the administration of from 1/8 to 1/6 grain of strychnin during twenty-four hours. Five thousand examinations were made in all on 31 cases of typhoid fever, 4 cases of pneumonia and 15 other cases. He finds that strychnin has no influence on the blood pressure in febrile cases. The visit of a friend, the appearance of the dinner tray or change of position would do more to send the pressure up than the administration of strychnin. He does not wish to say that the drug is of no value in these conditions, however.

DISCUSSION.

Dr. Alfred Stengel, Philadelphia, said that the systolic pressure is sometimes increased by strychnin, but that the diastolic pressure is not changed.

Dr. Hobart A. Hare, Philadelphia, said that in his opinion strychnin is not a cardiac stimulant, but that it acts as an irritant to the nervous system in general. He is satisfied that the drug is often abused in typhoid fever and similar conditions. It ought to be determined whether strychnin raises the blood pressure in healthy persons. We ought not to speak of the heart and the vessels as separate parts of the circulatory system. When improvement follows the use of strychnin it is because of its influence on the nerve supply of the circulatory apparatus.

Dr. Cabot said that he noted no results when strychnin was suddenly withdrawn.

A Supposed Cause of High Tension in Nephritis.

Dr. W. H. Thomson, New York City, read this paper. High tension pulse occurs so early in nephritis that it must be due to the presence of a general vaso-constricting agent in the blood, similar to adrenalin. Such an agent would cause shrinkage of the kidney and interference with the excretion of urea. The prolonged influence of such an agent would lead to endarteritis, with degeneration of the vascular wall and cardiac changes. Aconite is the best vaso-dilator in nephritis, much more effective that the nitrites. Its use is followed by marked increase in the elimination of urea. In the production of interstitial nephritis ischemia antedates inflammation.

DISCUSSION.

Dr. George L. Peabody, New York City, said that the administration of aconite does increase the elimination of urea.

Poisoning by Illuminating Gas. A Clinical Study of Ninety Cases.

Dr. W. Gilman Thompson, New York City, read this paper. Of the 90 cases studied, all of which had been in coma for at least one hour, 17 were fatal. At this ratio, the 288 fatal cases of illuminating gas poisoning last year would indicate 2,000 as the total number of cases of this form of accident. This frequency is due to the gas stove and the ignorance of the foreign population. He does not think the deprivation of oxygen explains all the symptoms. It is likely that carbon monoxid is a poison having specific action on the nervous system. There appears to be a constant leucocytosis, from 18,000 to 50,000, which persists for a number of days. This leucocytosis is due to the polymorphonuclear cells. There is an increase of chlorids and urea in the blood. There is an irregular temperature in all cases. Respirations often fall to three or four per minute. The nervous symptoms include tremor, twitchings, coma, delirium, convulsions, rigidity, etc. Phlebotomy and saline infusion are in the main beneficial and should be thoroughly used. There were 12 autopsies in the 17 fatal cases. The brain was soft and edematous, there was internal hydrocephalus, softening in the basal ganglia with capillary hemorrhages, and dilation of the cerebral capillaries. Pneumonia was infrequent.

DISCUSSION.

Dr. S. Weir Mitchell, Philadelphia, said that illuminating gas varies very much in composition in different cities.

Dr. Alfred Stengel, Philadelphia, said that the experiments of Darrah showed that animals which were severely poisoned could not be saved by venesection and infusion, but that they could be saved by the injection of defibrinated blood. He referred to two cases of poisoning in human subjects, one of which was fatal and the other recovered.

Dr. George L. Peabody, New York City, said that the treatment by venesection and saline infusion is logical. Defibrinated blood is difficult to obtain and the surgeons often fail to get it into the circulation. The inhalation of oxygen is worthless. He has seen a case in which coma lasted over four weeks, which recovered without sequel.

Dr. Francis P. Kinnicutt, New York City, referred to the extraordinary ruddy coloring of the face in these patients. The depth or length of coma can not be considered a basis for prognosis. He has tried oxygen thoroughly without benefit.

Dr. Hobart Amory Hare, Philadelphia, said that with Edward Martin he had concluded that if animals poisoned with illuminating gas breathed pure oxygen gas, more recovered than when oxygen was not employed. Defibrinated blood is procured with difficulty and he fails to see how it could absorb oxygen.

Dr. Solomon Solis-Cohen, Philadelphia, said that carbon monoxid is the dangerous element in illuminating gas. There are other dangerous constituents such as the hydrocarbons of the methane group.

Dr. Thompson said that the gas varies in the different parts of the city of New York and with the coal supply. Recent investigations show that the carbon monoxid is the poisonous element and that the hydrocarbons are not so poisonous. The effect of the gas on the hemoglobin is not the only effect, although it is important. In many cases of coma the blood is not completely saturated with carbon monoxid.

(*To be continued.*)

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. *Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.*]

No Carbon Cop.

Lavage in Children.

A. Caille, in the *Post Grad.*, states that the most convenient and at the same time the most thorough way of washing out a child's stomach is by means of a fountain syringe attached to a glass T-canula which has a flexible catheter at one end and a waste tube at the other. The child should be held upright in the nurse's lap with the head secured in the forward position to allow saliva and the vomit matter to escape from the mouth. Care must be observed not to insert the tube into the larynx and the tube should not be so large as to compress the larynx. When the clear cry of the child is heard the tube is not in the larynx. In letting in water the stomach must not be filled to overflowing unless it is necessary to expel large curds which would not go through the No. 12 or No. 14 catheter. Overflowing the stomach is not safe, except when the child's body is bent forward or the child lies on its side. Stomach washing may also be accomplished by having the child swallow warm water in the ordinary way, and subsequently inducing vomiting by the introduction of the finger into the throat.

Lavage, according to Dr. Caille, is indicated in:

Acute gastritis, acute poisoning, cholera infantum, chronic indigestion with atony of the stomach. In difficult feeding cases. In persistent vomiting, and previous to operations on the stomach.

When it is necessary to simply clear the stomach of its irritating contents a single washing is sufficient. In chronic cases washing every other day is sufficient. The irrigation fluid should be boiled water at the body temperature; occasionally it is well to add a teaspoonful of the bicarbonate of sodium to render the solution alkaline in reaction.

LOW AND HIGH ENEMATA AND COLONIC INFLATION.

A soft rubber catheter should be used to irrigate the colon attached to a fountain syringe. The colon may be distended with boiled water, medicated water, starch water, soapsuds, oil, air or carbonic acid gas. The high enema should be administered through a long colon tube.

Indications for flushing the colon are as follows:

1. To secure bowel action, using soapsuds water one-half to two pints, at a temperature of 101 to 103 F.
2. To stimulate in circulatory failure; to prevent shock and collapse before chloroform anesthesia, and before and after operations.
3. In renal insufficiency, uremia, irrigate for twenty minutes at 110 F. with Kemp's flexible tube.
4. In jaundice, irrigate with cold water at 60 F., or warm water at 110 F.
5. To reduce temperature, irrigate at 60, 70, 80, or 90 F. Cold irrigations depress the heart.
6. To replace lost body fluids, irrigate at 110 F., as in weakness from hemorrhage.
7. To overcome intestinal obstruction.
8. To nourish per rectum.

Low enemata are given with a short tube and have about the same indications as the high injections, but are not so effective. They are sometimes of benefit in subacute local inflammations of the pelvic organs, but are ordinarily employed to secure bowel action.

Cough in Bronchitis.

The following combinations are recommended by *Merck's Report* in the treatment of the cough of bronchitis:

R.	Codeinæ	gr. iv		25
	Ammon. chloridi	ʒii	8	
	Syr. ipecacuanhæ	ʒiiss	10	
	Spts. etheris nitrosi	ʒiiss	10	
	Ext. scillæ flu. comp.	ʒi	4	
	Syr. pruni virg. q. s. ad	℥iv	120	

M. Dissolve the codein in about two teaspoonfuls of water with the aid of a small quantity of dilute hydrochloric acid; then dissolve the ammonium chlorid in the syrup of wild cherry and add to the other ingredients. Sig.: One teaspoonful every three or four hours.

As a stimulating expectorant the following:

R.	Ammon. chloridi	ʒi	4
	Syr. scillæ		
	Syr. pruni virg., āā	℥ss	15
	Olei anis.	gtt. iii	20
	Tinct. sanguinariæ	ʒi	4
	Mist. glycyrrhizæ co. q. s. ad	℥iv	120

M. Sig.: One teaspoonful every three hours.

As a sedative mixture the following is of service:

R.	Pot. bromidi			
	Pot. bicarb., āā	gr. xx	1	30
	Vini ipecacuanhæ	m. xx	1	30
	Glycerini	ʒi	4	
	Syrupi	ʒiv	15	
	Aquæ destil. q. s. ad	℥ii	60	

M. Sig.: One teaspoonful every three hours.

Guaiacol in Parotitis.

Ragozzi, in *British Med. Jour.*, recommends guaiacol externally in the treatment of mumps in the following proportions:

℞.	Guaiacol	ʒi	4
	Lanolini	ʒx	40

M. Ft. unguentum. Sig.: Apply locally twice a day and cover with oil silk.

It is also of service in the treatment of orchitis from whatever cause, and especially in those cases secondary to parotitis. Its beneficient action is probably due to the neutralizing power on the toxins circulating in the blood. The guaiacol is absorbed for it has been detected in the saliva in fifteen to thirty minutes after its application. This application, in mumps, reduces both the pain and the swelling within a short time after its application.

Cystitis.

The following combinations are recommended by *Med. Record* in the treatment of cystitis:

℞.	Liq. potassæ		
	Olei santali, āā	ʒii	8
	Aq. cinnamomi q. s. ad	℥viii	240

M. Sig.: Two tablespoonfuls three times a day; or:

℞.	Potass. bromidi			
	Sodii bicarb., āā	ʒiss	6	
	Ext. belladonnæ	gr. iv		25
	Ext. buchu	ʒi	4	
	Syr. sarsap. comp. q. s. ad	℥iv	120	

M. Sig.: One tablespoonful three times a day, in water.

And for chronic pyelitis accompanied by pain the following combination is recommended:

℞.	Terebenthinæ (Venice)			
	Pulv. camphoræ, āā	ʒiss	6	
	Ext. opii	gr. v		30
	Ext. aconiti rad.	gr. iii		20

M. Ft. pil. No. xx. Sig.: One pill every eight hours, with a small glass of the infusion of uva ursi sweetened.

Scabies.

Renault, in *Jour. des Pract.*, recommends the following combination in the treatment of scabies:

Cleanse the skin with a soft soap and an hour later apply the following combination:

℞.	Sulphuris sublim	℥i	30
	Potass. carb.	ʒiii	12
	Adipis	℥ss	15

M. Ft. unguentum. Sig.: Apply locally and leave in place for twenty-four hours.

As a milder ointment the following combination is recommended after thoroughly cleansing the skin:

℞.	Glycerini	℥i	30	
	Sulphuris sublim.	℥ss	15	
	Pot. carbonatis	ʒiiss	10	
	Tragacanthæ	gr. iv		25
	Olei lavendulæ	m. v		30

M. Ft. unguentum. Sig.: Apply locally.

If pruritus persists after this antiparasitic application the following combination:

℞.	Acidi carbol.	gr. xv	1
	Glycerini	℥iii	90

M. Sig.: Apply locally two or three times daily to allay the itching.

Acne.

The following combination is recommended by *Applied Ther.* in the treatment of acne:

℞.	Pot. sulphureti		
	Zinci sulph., āā	gr. xx-ʒiss	1.30-6
	Aquæ	℥iv	120

M. Sig.: Apply locally as a wash.

As an ointment the following is recommended:

℞.	Sulph. precip.	ʒss-ii	2.-8
	Ichthyol	ʒi-ii	4.-8
	Liq. petrolati q. s. ad	℥i	30

M. Ft. unguentum. Sig.: Apply locally.

The following lotion containing resorcin is of service:

℞.	Resorcini	ʒss-ii	2.-8
	Acidi borici	ʒi-ii	4.-8
	Zinci sulph.	gr. xx-xxx	1.30-2
	Alcoholis	℥ss	15
	Aquæ destil. q. s. ad	℥iv	120

M. Ft. lotio. Sig.: Apply locally.

Corrosive sublimate is sometimes employed as lotion in the following strength:

℞.	Hydrarg. chloridi corros.	gr. iv		25
	Zinci sulph.	gr. xx	1	30
	Tinct. benzoini	ʒii	8	
	Aquæ q. s. ad	℥iv	120	

M. Sig.: To be applied locally.

Gelatin in Infantile Diarrhea.

Weill, in an abstract in *Ther. Review*, reports excellent results in the use of gelatin in infantile diarrhea. He recommends it in doses ranging from 1½ to 2 drams (6.-8.) daily, which greatly diminishes the number of stools. This proportion is useful only in simple gastro-enteritis in children, and where the trouble affects only the stomach and bowels. The action of gelatin is not bactericidal as bacteria grow on gelatin. It has been proven by animal experiments that if gelatin and a laxative are given simultaneously or if the laxative is given after the gelatin, its laxative effects are interfered with; if the laxative precedes the gelatin, its effects are not modified. The conclusions arrived at, then, are that the gelatin neutralizes the toxic products produced by the disease in the intestines.

Eczema of the Palms of the Hands.

The following combination has been recommended to the Therapeutic Department of The Journal by Dr. C. C. Gentry of Antrim, Pa., in the treatment of eczema of the hands, especially eczema involving the palms of the hands. Although our attention has not been previously called to a similar combination, it deserves attention on the recommendation of Dr. Gentry. The formula is as follows:

℞.	Formaldehyd (40 per cent.)	gtt. x-xv	.65-1
	Petrolati	℥i	30

M. Sig.: Apply thoroughly night and morning.

Medicolegal.

Rupture of Blood Vessel Lifting Not Accidental Injury.—The Second Apellate Division of the Supreme Court of New York says that in Niskern vs. United Brotherhood of Carpenters and Joiners, the theory of the plaintiff's case, brought to recover a disability benefit, was that on the occasion referred to he was suffering from a hardening of the blood vessels of the body, known in medicine as "arterial sclerosis," and that the strain to which he was subjected in lifting heavy timbers ruptured a diseased blood vessel and produced a condition unfitting him for further labor at his trade. But the court does not think that his testimony, which amounted to nothing more than a statement that he suddenly became dizzy while he was engaged in endeavoring to put up the frame and the rafters upon an addition to a house in course of construction, sufficed to make out an accidental injury within the meaning of the brotherhood's constitution. It says that the most that, by the most liberal inference could be deemed to have occurred was that he put forth an effort in the performance of his work which proved too much for him in his physical condition as then existing, and that he was consequently unable to prosecute his work any further. This result was in no sense an accidental injury.

Health and Custody of Minor Child.—The Supreme Court of California reverses, in re Salter, an order appointing the maternal grandmother guardian of a child five years of age. The finding was that the father had not abandoned his child, and was a fit person to have his care and custody, but that the child was in delicate health and required the constant watching of a competent and experienced person; that his health and welfare would be better promoted by being placed for the greater part of the time in the custody of his grandmother; that the grandmother had a home in Pasadena, where the child could be kept and get the benefit of fresh air and exercise, whereas, if left in the custody of his father he would have no opportunity of being outdoors, except upon the public streets of the city of Los Angeles. The supreme court holds that the right of the father, he being competent, to have the custody and control of his child was not at all affected by the finding relative to the health of the child, and the better opportunity he would have for fresh air and exercise, at the home of his grandmother, than at the residence of his father. It says that even if the father were poor and unable to provide for the child as comfortably as his grandmother could, or would be compelled to maintain him at his place of abode in Los Angeles, under the circumstances found by the lower court, these considerations would furnish no legal ground for depriving him of the custody of the child. They applied merely to its material, temporal welfare, and, if such considerations were controlling, they could, in every instance where poverty was the misfortune of a parent, be invoked to deprive him of his child in favor of one more fortunately situated and better able to minister to its material comfort. Common humanity would be shocked at the serious maintenance of such a proposition.

Burden of Proving Insanity as a Defense to Crime.—The Supreme Court of Washington says, in the homicide case of State vs. Clark, that it was insisted that it is not necessary, in order to sustain the plea of insanity, that the fact of insanity be established by a preponderance of the evidence; but if, on the whole evidence, the jury entertain a reasonable doubt as to sanity, they must acquit. But the jury were instructed that every man is presumed to be sane and to intend the natural and usual consequences of his own acts, and that, as the law presumes a man to be sane until the contrary is shown, the burden of proving insanity as a defense to a crime is upon the defendant to establish by a preponderance of the evidence, and unless insanity is established by a fair preponderance of the evidence the presumption of sanity must prevail. The rule the defendant contended for is sustained by the Supreme Court of the United States and by the highest courts of the following states: Florida, Illinois, Indiana, Kansas, Michigan, Mississippi, Nebraska, New Hampshire, New York, Tennessee, Vermont and Wisconsin. On the other hand, the highest courts of the following states maintain the rule that, where insanity is set up as a defense in a criminal case, it must be established by a preponderance of the evidence: Alabama, Arkansas, California, Connecticut, Delaware, Georgia, Idaho, Iowa, Kentucky, Maine, Massachusetts, Minnesota, Missouri, Nevada, New Mexico, New Jersey, Ohio, Pennsylvania, South Carolina, Texas, Utah, Virginia and West Virginia. The rule in England is followed by the last-named class of states. In the states of Oregon and Louisiana the defendant is required by statute to prove insanity beyond a reasonable doubt. And, notwithstanding the weighty reasons advanced by the courts in the class first named, the Supreme Court of Washington says that it desires to adopt the rule laid down by the trial court in this case. It says that it will be seen by an examination of the authorities cited that the cases in the different states are in irreconcilable conflict as to the quantum of proof upon the question of insanity. All, however, concede that the presumption of sanity prevails, and that there must be some evidence to remove this presumption. In the first class of cases it is held that, where the evidence raises a reasonable doubt as to the sanity of the defendant, he must be acquitted; in the other, that a reasonable doubt is not sufficient, but the defendant must establish insanity by a preponderance of the evidence. In the first class named the reason for the rule is that the presumption of innocence always attends an accused person, and that the burden of proving all the elements of the offense rests upon the state, and never shifts; that, when the defendant's sanity is put in issue, the state must prove it beyond a reasonable doubt, because, without a mind capable of crime, there can be no crime committed; and therefore, if the jury entertain a reasonable doubt as to the sanity of the accused, it follows that they are in doubt as to his guilt. The reason for the rule adopted in the other class of states is that sanity is the natural condition of man, and therefore every man is presumed sane until the contrary is made to appear; that when the commission of a crime is admitted or clearly proven, and insanity is alleged as a defense, it being an independent, affirmative defense, and opposed to the natural and usual order of things, must be established by a preponderance of the evidence. Another reason given is that the presumption of sanity is necessary for the wellbeing, safety and protection of society and for the administration of justice, and neutralizes the presumption of innocence on which the rule of reasonable doubt rests, and therefore leaves the accused, when asserting his insanity, to show the fact by a preponderance of the evidence. Another reason for the rule is that it is the only safe rule for society, while it is also just to the accused. The distinction between the quantum of proof necessary to raise a reasonable doubt and that necessary to constitute a fair preponderance of the evidence is more fanciful than real. When evidence is sufficient to raise a reasonable doubt, as such doubt is usually defined and understood, it may also be said in a sense to proponderate. The distinction, therefore, while it may be fruitful of philosophical and theoretical discussion, is of little practical value. Insanity, when it exists as a fact, is easily and readily proved. When it does not exist in fact it is easily feigned and difficult to disprove. For this latter reason it is the usual defense when there is no other. It is no injustice to a defendant to presume that he is sane, and to require him to prove the unnatural condition of mind, which he alleges as a defense for a crime admitted, and to relieve him from a penalty justly due to men in their natural ondition.

7 Address to the Members of the Philadelphia Pediatric Society, at Its Eighth Annual Meeting, Jan. 12, 1904. D. J. M. Miller.

1. **Infantile Diarrhea.**—Rotch reviews the symptoms and characteristics of infantile diarrhea, summing up the facts that we are warranted in accepting up to 1897 in substance as follows: 1. There are no uniform symptoms enabling us to diagnosticate the special lesions of acute or chronic cases. In the latter it is not only impossible to determine what part of the enteric tract is affected, but even to state definitely that there was a primary specific lesion of the intestine or any marked lesions present. 2. In the acute cases it was possible to determine usually whether the small or large intestine was most involved, this being done by the small number and comparatively large size of the dejecta representing the small intestine and the large number and small amounts from the large intestine. 3. The temperature is of considerable aid in differentiating the non-inflammatory diarrhea represented by the fermental group, from the inflammatory diarrheas represented by the ileocolitis group. There are no marked lesions in the former, but they are present in the latter, the temperature is high, followed by crisis in the former and high or moderate, decreasing by lysis, in the latter. 4. Knowing where the stress of the lesion is situated our treatment should be by the mouth in diseases affecting the upper intestine and usually of the fermental class and by the rectum in diseases involving the lower part of the intestine and ordinarily of the ileocolitis type. 5. Pus or pus and blood in the intestinal contents are usually of serious import as pointing toward grave pathologic lesions. New light, however, has been thrown on the subject of late years by studies, especially in Japan. The part played by the bacillus of Shiga is noted at some length. During the past summer Rotch had special work done for him at the Infants' Hospital, Boston, for detecting this organism. In all the 61 cases examined when the bacillus was found the organism isolated was the "Mannit acid type," the same as found by Park in the Bronx epidemic. The differences between the Mannit acid type and the Shiga type are pointed out at some length and an analysis of the 61 cases shows that the *Bacillus dysenteriæ* was the cause of 16 per cent. of all the 61 cases examined. It may give rise to either the fermental diarrhea or that known as ileocolitis. In 30 per cent. it was found to produce the former, in 70 the latter. A causal connection, however, was demonstrated only in 6 per cent. of the fermental diarrheas examined, but on the other hand the *Bacillus dysenteriæ* is probably the most frequent cause of cases examined. The symptomatology outside the bacteriologic findings is not as yet to be relied on and the presence of specks of blood in the intestinal contents does not necessarily mean infection, nor is a high or low leucocyte count of diagnostic value. The distinction between the fermental diarrhea and the ileocolitis is probably connected with the extension of the pathologic process and this depends on the nature of the infecting organism and the severity of the infection. Infectious diarrheas are probably caused by a variety of organisms and the *Bacillus dysenteriæ* is only one of these, but can be most often connected with a condition corresponding to ileocolitis. The prognosis depends on our earlier clinical knowledge. Pus in the dejections is of serious import and the degree of general sepsis is to be carefully considered and estimated. There has been no great advance in the treatment. It is probable that the success will be best, as formerly held, by the mouth treatment when the small intestine is affected and through the rectum when the large one is affected. He thinks it rational to give bismuth, bearing in mind its limited therapeutic properties. Clearing the intestines of bacteria by laxatives, supporting the strength and combating the nervous symptoms and fever are the chief indications. The serum treatment is, of course, experimental. As tested on animals it is very effective, but so far as the Shiga serum was concerned, we have no special evidence that it can be of much aid in mixed infection. In conclusion he remarks on the importance of treating at once what may seem to be even the most simple form of diarrhea.

3. **Landry's Paralysis.**—Two cases are reported by Diller, both of longer than the usual duration. In the first case it would seem that the lower motor neuron was progressively involved from below upward. The anatomic changes with their resultant symptoms might have been due to alcoholism. In the second case there was a progressive paralysis from below of purely motor type for the first four months while enlargement and tenderness of the nerve trunks were features of the last two months of the illness. This case he considers as a neuritis or rather more than a neuritis. It seems likely that the entire lower motor neuron was involved as in the first case. The sudden severe pain at the onset was a striking feature.

4. **Septal Spurs.**—Spratt advocates the use of the flap operation method first published by Heylen in 1847, consisting of first reflecting a flap of mucous membrane from the projection and removing the cartilage or bone with scissors. He declares that this is scarcely ever employed at the present day, but that with adrenalin and cocain it is perfectly practicable and easy. The advantages over the usual methods are the early healing in three or four days; adhesions are impossible, as no raw surfaces are left, and there is no fear of scab formation. Perforation is a complication that need never occur. This window resection operation, he says, can generally be done in 25 or 35 minutes, and the difficulties appear greater than they really are.

5. **Laryngeal Tuberculosis.**—The following are the conclusions reached by Skillern:

1. Local treatment is always beneficial even if it only relieves the most distressing symptom, *i. e*, pain.
2. It depends entirely on the general condition of the patient what form of local treatment is most advisable.
3. While laryngeal tuberculosis in some cases may be entirely cured, there always remains more or less chronic laryngeal catarrh.
4. That extensive surgical procedures in cases in which the lungs are deeply involved except as a palliative treatment are unjustifiable.
5. That extensive curettement should only be employed in those cases in which there is a fair chance of curing the disease and when it is necessary to prolong life a short time.
6. The prognosis depends more on the general systemic condition of the patient than on the throat lesion. It naturally follows that the more severe the throat lesion the greater the degree of constitutional weakness.
7. If a case is seen at an early stage of its development, the

prognosis is good provided of course the concomitant lung disease is responding to treatment.

8. When there is much ulceration and loss of tissue, absolute cure is impossible, but such an amelioration of symptoms may be brought about as to render the patient fairly comfortable for the rest of his existence.

9. The best results are obtained when the tuberculous deposit in the larynx is localized.

6. **Flagella Staining.**—After giving their method Johnston and Mack remark that the essentials are: A clean cover glass, but little organic matter in the film to stain and no heavy background, avoiding fixing the film in the flame, but allowing the mordant to fix it, avoiding heating either mordant or stains on the films, as it tends to produce a precipitate and background. Finally, the all-important prerequisite is to have a film containing organisms with flagella extended. This condition fulfilled, no special technic is required other than the use of mordant.

8. **Diastolic Murmur in Diagnosis.**—Hollis describes the variations in diastolic murmur in aortic and pulmonary insufficiency, persistent ductus arteriosus, aneurismal diastolic murmurs, mitral stenosis, cardiorespiratory influences and pericarditis and pleuropericardial conditions. The details are too elaborate to permit of abstracting in the space we are able to give. Six cases are reported illustrating some of the types.

9. **Bovine Tuberculosis.**—Ravenel points out the possibilities of infection of the human subject by bovine tuberculosis and claims that Koch demands a higher standard of criticism than he is willing to have applied to himself in his comments on the cases that have been published. His conviction is that the two diseases are essentially the same and intercommunicable, and that cows with tuberculosis of the udder are not alone to be dreaded. While at the present time the weight of evidence is in favor of the view that the chief source of infection in children is through the respiratory passages by the human tubercle bacillus, he thinks it has been proven conclusively that the bovine tubercle bacillus is responsible for a certain proportion of deaths from tuberculosis and there is strong evidence, he says, to show that the number of children infected from bovine sources is quite large. Whether large or small, it is our duty to guard against the use of milk from tuberculous cattle for food.

10. **Chronic Myocarditis.**—Bell discusses myocarditis in its broadest sense, including any conditions manifesting themselves clinically in the weakened myocardium resulting largely from fibroid or fatty changes in persons at or beyond midlife. He finds it more frequent in men. The long-continued, even moderate, use of alcohol, together with tobacco, is one of the most potent factors in its production. Gout or gouty diathesis and syphilis are also often responsible for the condition. The rational symptoms are at first vague and death may occur suddenly without evidence of symptoms or physical signs. Breathlessness, amounting to dyspnea on exertion, is one of the earliest and most constant symptoms. Slight vertigo, headache, precordial distress, palpitation and later attacks of angina are among the more common symptoms. The pulse becomes irregular in rate, rhythm and force, perhaps intermittent. Slight overwork of the heart produces attacks of palpitation and later attacks of severe cardiac asthma, especially at night. In other cases the breathing is of the Cheyne-Stokes type, and in still other cases precordial pain occurs. Unless the condition is promptly recognized, it gradually increases. In the beginning of every suspected case a complete history should be taken, especially as to age, family tendencies, habits and previous disease. The urine should be carefully investigated for renal disease. The diagnosis is based largely on the history, age, state of the vessels, and symptoms. As to the exact nature of myocardial changes present, we can only infer. He divides the clinical course into two periods as regards treatment: 1, primary breathlessness, precordial distress and irregular pulse; 2, advanced weakness and the more serious symptoms. Each case should be studied by itself. The first endeavor should be to remove every cause of cardiac irritation; second, regulate the diet, exercise and habits so as to bring the general nutrition as well as that of the heart muscle up to the highest point. In addition to hygienic and dietetic measures, tonics such as strychnin, arsenic, etc., are indicated. In the early cases when the pathologic changes are not very far advanced, graduated exercise is often beneficial. In the great majority of cases, however, absolute rest in the recumbent position is necessary for at least a few weeks. The patient should be advised to sleep and eat regularly, taking three meals a day. It is attention to such little things as eating, drinking and doing which secures success. Before the use of saline baths, advanced arterial fibrosis and aneurism must be excluded, as also advanced cardiac insufficiency with dropsy. He begins with a bath of ten minutes' duration in water at 98 degrees and 1 per cent. saline and 1/10 per cent. calcium chlorid. The second bath is gradually lowered to 90 and the subsequent ones are kept at that temperature, gradually increasing the chlorids, and carbonic acid added by the tenth day. He continues the baths for five or six weeks, omitting every fourth day. In advanced cases absolute rest in bed must be enjoined. For reduction of the high arterial tension in many cases we rely mainly on the iodids and nitrites. He has found iodid of sodium in 3 to 5 grain doses three or four times daily very useful. He emphasizes the value of long-continued, very small doses of digitalis combined with a vasodilator in myocardial disease or arterial fibrosis or chronic renal disease. With irritable stomach and scanty urine and high blood pressure it may be given by the rectum with good results. A saline in the morning, preferably magnesia sulphate, aided by an occasional bedtime dose of calomel, is also excellent. When angina pectoris occurs prompt inhalation of amyl nitrite and the subcutaneous use of morphin and nitroglycerin is advised. The attendant should instruct the nurse how to administer these in case of emergency. In conclusion he emphasizes the importance of recognizing the earliest symptoms.

11. **Appendicitis.**—Best advocates under certain conditions which are unavoidable in general practice, the use of medical treatment in appendicitis. The mortality, he thinks, may be fairly approximated somewhere between 10 and 15 per cent., and he holds that the results of surgical treatment are a little higher than its ardent advocates claim at the present. He believes in the majority of cases abscess opens into the intestine and the patients recover. Where it ruptures into the peritoneal cavity surgical interference is always indicated. Fulminating cases are frequently those which the surgeon does not see in time and the medical practitioner sees too soon for his own comfort. They usually terminate fatally under either medical or surgical treatment.

12. **Shock.**—Crile reports experiments with alcohol, nitroglycerin and amyl nitrite in shock, using the drugs by intravenous administration. With alcohol the first effect was a decline in the blood pressure; in the majority of cases a compensatory rise followed, but in a number of instances this was lacking. In very few was there a rise in the blood pressure. In animals reduced to varying degrees of surgical shock, the usual effect of an average dose of alcohol was still further depressing. In smaller doses little effect was noticed. In a few cases, in deep shock, a considerable dose was followed by almost immediate death. The more profound the shock the more marked the depressing effect of the alcohol. In a number of experiments alcohol was given prior to the procedures intended to produce shock, but he is not sure that it rendered the animal more susceptible, though he is quite certain that the susceptibility was not diminished. The immediate effect of nitroglycerin and amyl nitrite on the pulse was an increase of volume and a decrease in frequency. Sometimes the respiration was slightly increased, but more frequently diminished. The blood pressure in almost every instance fell, and usually rapidly. In a few exceptions there was no effect. A rise in the blood pressure was rarely observed, and was then

only temporary and usually followed by a fall. Compensation usually took place in a few minutes, the rising curve being more gradual than the fall. The portion of the curve representing the deepest part of the decline was rounded. In the majority of experiments compensation was complete. Where it was not equal to that before the administration of nitroglycerin, it was usually lower, and when repeated doses were given—each twice as large as the preceding one—the effects were proportionately increased. Most of the animals tolerated very large repeated doses; excessive doses produced convulsions and respiratory failure, and the blood became darker before the animal died. Where the animal was in deep shock and the blood pressure gradually falling there was no evidence to show any decrease in the rapidity of the decline. As near as can be estimated, nitroglycerin distinctly increases it and amyl nitrite was in every respect similar in its effects to nitroglycerin. On the whole nitroglycerin and amyl nitrite increase the shock. The experiments appear to have been performed exclusively on dogs.

13 *Contribution to the Etiology of Idiocy and Imbecility William N. Bullard.
14 A Sigmoid Band of Unusual Origin. Operation. Relief. Arthur L. Chute.

13. **Idiocy and Imbecility.**—In the 258 cases examined in the neurologic clinic of the Children's Hospital of Boston, there were 176 where the question of an acquired or congenital defect could be determined. Of these 113 were congenital and 63 were non-congenital or acquired cases. This fact was somewhat of a surprise. The etiology of the non-congenital was much simpler than the congenital. About 13 per cent. were probably traumatic, possibly as many as 19 per cent. Disease played a notable part in a number of cases. There were a number in which post-natal disease was the most potent cause, but the evidence was not absolute, and examples are given. The nature of the disease causing imbecility or idiocy is not always clear, but that it is intracranial is evident, and congenital cases are divided into intranatal or prenatal. Bullard is inclined to attribute the great majority of them to the prenatal rather than the intranatal cause. The only clinical evidence of the latter would be a direct history of accident or injury and the occurrence of unconsciousness, convulsions or acute cerebral symptoms immediately on birth as indicating this probability. Out of 38 cases in which the cause was probably or possibly intranatal in 18 cases forceps were used, but he has not been able to find any evidence of injury from the forceps. He thinks delay in the use of the instrument is just as likely to produce the condition as their unskillful employment. Among the prenatal cases there is a small number in which they had data in relation to conditions during pregnancy. In 11 there was a history of much worry on the part of the mother; there were 9 cases in which the mother had a more or less severe fall and 2 other cases of trauma; there were 3 cases of illness of the mother at the time and 2 in which the mothers were very weak, but with no definite disease and 1 where the mother was over-worked in a factory. He considers these a most important group for investigation from an etiologic point of view. Heredity is undoubtedly a potent factor, but the number which could be absolutely determined as probable was apparently not very large. Syphilis in the parents and alcoholism are other important factors. The latter, however, is often complicated with the former. Maternal uterine disease Bullard considers a very important cause, and many unexplained cases may be due to it. Some 12 cases of hydrocephalus are noted with reference to the question of the cause. These statistics, Bullard remarks, are only preliminary to those which he hopes to obtain in the near future.

20 Diabetes in Childhood. Hubert N. Rowell.
21 The Diagnosis of Smallpox in the Papular Stage. (To be concluded.) D. H. Reed. A. G. Miller and S. J. Bumstead.

15. **Parenchymatous Change in the Kidneys.**—Tomlinson concludes from clinical experiences, which have been largely verified by a study of similar conditions, experimental and otherwise, in the lower animals that there is as much difference in the kidney capacity of different individuals as there is in that of their other vital organs and the nervous system; that some individuals are born with defective kidneys, not necessarily anatomically, but functionally imperfect, and that in such chronic degenerative processes may be set up early in life. They are always to some extent victims of chronic autointoxication because of imperfect elimination, and in these the irritation resulting from retention of waste products of retrograde metabolism favors a chronic congestion of the kidneys, so that from causes that do not seriously affect an ordinary individual, there may and does arise, acute involvement of the parenchyma of the organs, checking elimination and resulting in more or less explosive outbreaks involving the whole organism, especially the nervous system.

16. **Juvenile Tabes.**—Gordon reports a case in a girl who had marked tabetic manifestations superimposed on acute anterior poliomyelitis in infancy. This adds another case to the few of juvenile tabes, and shows that hereditary syphilitic tabes and acquired syphilitic tabes are identical in their symptomatology.

17. **Resuscitation After Death from Chloroform.**—Kemp and Gardner discuss the subject of heart massage, giving credit to Schiff and possibly Ludwig, though as far as its application to the human subject is concerned, Prus can claim priority. They give the details of their experiments and discuss the limitations of the usual methods, describing the different methods of massage. The first consists in trephining the sternum and compressing the base of the heart against the chest wall. This, however, will be impracticable in the human subject. 2. Resection of several ribs and insertion of the hand into the left thorax and rapid compression of the heart. The objections to this are the greater tendency to shock and some danger of tearing the pericardium. The third method, which is the most rational and safe, is placing the animal in the Nélaton position. This thrusts the heart forward against the chest and somewhat upward. An incision is made over or slightly below the apex. If more space is required a small piece of the fifth or sixth ribs may be resected. The index or middle fingers are passed over the margin of the heart and behind it, near the apex, and pressure made on the heart against the chest; or, the opening being enlarged, the fingers may be placed behind and the thumb between the apex and chest wall, and the heart squeezed rapidly between them.

19. **Glycosuria.**—Croftan has succeeded in preparing a pancreas-muscle-hemoglobin extract by coagulation with alcohol, mixing in varying proportions, while the tissues are still warm. He has used this in several cases in the hospitals, noting a marked decrease of glycosuria in cases of diabetes. He says he will not attempt to discuss the character and composition of the active principle that can pass unchanged through the stomach and bowel into the blood stream beyond and there have its effect, but calls attention to the resemblance between this preparation and thyroid. In both cases, he says, we are dealing with substitution therapy and supplying something that is lacking. Whether or not the ultimate effect of the pancreas preparation in diabetes will be curative as thyroid is in myxedema, remains to be determined, and he suggests that by giving these extracts the inherent sugar-destroying power of the organ might be granted a rest, and this act beneficially by restoring the normal tone and educating the perverted glycolytic function back to normal.

26 The Hospital Car; Its Equipment, Uses and Importance. William W. Sanford.
27 The Prevention of Disease. John B. Huber.
28 *The Syrian Climates. Hanna M. Rahmi.

22. **Menstruation.**—Goffe holds that menstruation is a result of ovulation, and that it is in fact what it has already graphically been called "a disappointed pregnancy." The dominant factor is the ovary and ovulation. From the ovary or its sympathetic nerve ganglia in the pelvis and abdomen there springs the reproductive impulse, but menstruation is a retrograde process, the result of a failure of fertilization of the ovum, and he believes that the mucous membrane of the tubes, as well as the endometrium, participates in the process.

24. **Dentigerous Cysts.**—Cumston reviews the origin and pathology of these cysts. He declares that they are benign in every respect. The treatment is simply to open them after diagnostic puncture and remove all vestiges of lining membrane. Otherwise relapse is practically certain. In order to do this the cavity should be freely exposed by a large opening, and the curette, scissors and, if necessary, the thermocautery used. If any epithelial cells remain they may be a source of recurrence. After the cavity has been thoroughly cleared, it should be plugged with gauze for a few days so that the epithelium of the buccal mucous membrane and the granulations arising within the cystic cavity unite when the latter become filled. Any tooth or root protruding into the cyst should be removed. In large cysts it may be necessary to drain through the floor of the nose. In the lower jaw it may be impossible to attack the tumor by the buccal cavity and a cutaneous incision is required and here sufficient resection of the outer shell of the bone should be made.

28. **The Syrian Climates.**—Rahmi describes the different climates which can be reached within a few hours by means of the Beirut and Damascus railroad, including the mild subtropical shore climate, the Alpine Lebanon climate, the sedative moist mountain climate of the western slope and the dry eastern slope. He thinks that Syria, in the region around Lebanon, has a combination of climates without equal anywhere else in the world.

29 *A Sketch of the Past and Future of Embryology. A. C. Eycleshymer.

29. **Embryology.**—Eycleshmyer's article is a historical sketch of the development of embryology, with a statement of the recent theories and advances. Embryology of the future will have to advance on both morphologic and experimental lines. There is much yet to be known of embryology of the lower vertebrates and of the development of changes in the mammals. As to the human species there are great gaps in our records. There is not extant, he says, a description of a single vertebrate in which the organs and tissues have been followed until they reached the mature condition. We shall some day be able to follow the life-cycle of organs, tissues, cells and structural changes and thus have a basis for the interpretation of structures in disease. Still greater advances are to be hoped for along the lines of experimental embryology and the task for the future lies in the interpretation of the physical and chemical changes, explaining the growth and changes in the organs, etc.

33 *Animal Therapy in Tuberculosis. Edward T. Smith.
34 Typhoid Fever. Thomas Bagley.
35 Prostration of the Circulation. Louis Faugeres Bishop.

33. **Animal Therapy in Tuberculosis.**—Smith gives a report of the use of lymph prepared from the spermatic fluid of a young bull, which was gathered for a considerable time, and during which the animal was confined and fed on grain to develop the lymphatics. After bleeding the animal to death, the grey cerebral substance, the spinal cord, the ganglia, the lymph in the reservoirs and ducts and the mesenteric lymphatic glands were taken and with the addition of the semen, the mixture thoroughly triturated in a ball mill with an equal amount by weight of distilled water and half a grain of sublimed albuminate of gold to the ounce, added as a noncoagulant and preservative. The trituration was carried on for ten hours continuously, and after that time, microscopic examination showed the entire disintegration of the spermatozoa, lymphocytes, nerve cells and lymphatics; the emulsion was filtered through a porous filter at high pressure and afterward treated with ether or cold to remove the fats. It was then sterilized by carbonic acid gas under pressure. It is a clear, thick albuminous liquid and a true extract of the organs and secretions stated. Prepared with rigid antisepsis it is hard to contaminate and will keep for months if placed in an amber-colored glass stoppered bottle and kept in a dark, cool place. The compound is injected hypodermically in tuberculosis to the exclusion of all other remedies, preferably in the center and outer parts of the buttocks, subscapular spaces, and along the sides of the spinal column. The injections were given deeply, into the connective tissue, and not into the muscle, and left no induration. The dangers are superficial injections, haste, deficient massage, uncleanliness and too much force in the injection. If there is any pain from the injection, the solution should be dissolved with boiled or distilled water, but it is generally painless and he has had no ill results in thousands of injections. The dosage varies with the individual. In some severe cases he has given as much as ten minims every four to six hours until the severity of the symptoms is abated. Then the periods are lengthened. In other not so acute cases he has had good results from one daily injection of 20 minims. The usual dose is 15 minims night and morning. He insists on a plain nutritious diet, excluding raw fruits as well as vegetables, as they leave much residue. Constipation is generally overcome by the tonic effect of the lymph on the muscular coat of the bowels. It is a cell tonic and reconstructive. The treatment is kept up for three months or longer if it seems advisable. He reports cases of advanced consumption with hemorrhages, cavities, etc., cured by this treatment.

36. **Sarcomata of the Uveal Tract.**—These rare conditions are studied by Parsons, who tabulates and analyzes all the cases he has been able to discover in the literature.

39. ***Osmotic Disturbances in Glaucoma.***—Pusey makes the suggestion that variation in the osmotic capacity of fluids may be the cause of some cases of glaucoma. He thinks it seems probable that in varying osmotic pressure (probably a hypertonic condition within the globe) we have the explanation of the primary cause of the condition. Carrying out his experiments to determine this fact in sheep's eyes a striking change was found in the lenses. In certain concentrations of salt and sugar the lense became cataractous. A still more startling experiment was the clearing of the cataractous lenses of the salt solution by putting them in a weak solution of the salt or in distilled water and leaving them there for some hours. He thinks that some interesting fields of study and suggestions as to treatment are opened up in this investigation.

43 *Effect of Flood of 1903 on the Health of the Kaw Valley. M. A. Barber and John G. Woodin.
44 Eclampsia. M. T. Dingess.

43. **The Flood of 1903 in Kansas and Its Effects on Health.**—Barber, who is professor of bacteriology in the School of Medicine of the University of Kansas, sent out, in conjunction with John G. Woodin, a medical student, a large number of inquiries through the flood affected district as to the general effects on the health during the past year, the numbers of cases of typhoid fever since June 15, 1903, and in the corresponding period of 1902, and what proportion of these seemed due to the standing water, decaying drift, etc. Similar questions were asked in regard to malaria and other diseases. In all, about 60 answers were received. Some of the information given is that the number of typhoid cases has decidedly decreased in the latter of the two years, while there has been a slight increase of the malarial cases. In other respects there has been very little difference. The proportion ascribed to standing water is not strikiingly large in either year; both were wet years. It is difficult to summarize the opinions of physicians concerning the effects of the flood on the health as all do not give positive answers, but of those who do, scarcely 9 per cent. believe that, aside from the disorders due to the immediate effect of the flood such as nervous troubles, rheumatism, colds and the like due to exposure, it had any particular effect on the prevalence of disease. In a number of the replies the season of 1903 was accounted an unusually healthy one and eight of the respondents were of the opinion that the flood had had a beneficial effect in washing out the accumulated filth in cellars, ponds, etc. It should be remembered too that in most of the towns vigorous sanitary measures were taken after the flood and that these may have served not only to avert the dangers but to increase the general health. There was reason to believe that in some communities, at least, its effects were those of a beneficial, though a rather indiscriminate scavenger. It left standing no water or anything else, as one expressed it.

45 *Middle-ear Disease in Its Relation to Metastatic Abscess of the Liver and Other Viscera. S. MacCuen Smith.
46 A Contribution to the Pathologic Anatomy of the Internal Ear and the Auditory Nerve. Paul Manasse.
47 Contribution to the Pathology and Treatment of Diseases of the Accessory Nasal Cavities. F. Roepke.

45. **Middle Ear Disease in Its Relation to Metastatic Abscess and Other Viscera.**—Three cases are reported at length, and others have been observed by Smith, which point out to him the connection between liver abscess and otitic disease. In these cases the most notable early symptom was acute exacerbations of a chronic aural discharge, which, although usually innocuous, in a few cases became ichorous and should have pointed to a possible systemic infection. The most constant and characteristic symptom was severe pain in the right shoulder and neck appearing synchronously with the beginning of the hepatic suppuration. The pain and tenderness in the right hypochondrium unerringly indicated the liver as the seat of disease. The repeated chills, high temperature, and leaky skin showed the septic process likely to prove fatal. The marked accessions and remissions of temperature were typical of an acute suppurative hepatitis or multiple abscess of the liver. While jaundice was a constant factor, it was so irregular as to be of little diagnostic value, save as confirmatory. The history of secondary infection in each of the cases is sufficiently clear to warrant the conclusion that a metastatic abscess of the liver or other viscera might originate from suppurative disease of the ear.

Journal of Cutaneous Diseases, New York.

May.

48 Report of a Case of Bullous Lichen Planus. (Lichen Planus Pemphigoides). Martin F. Engman.
49 *Creeping Eruption: Its Relation to Myiasis. Louis P. Hamburger.
50 *Report of Personal Case of Papilloma of the Sole. T. D. Berry.
51 *A Rare Bromid Eruption. Lotta W. Myers.

49. **Creeping Eruption.**—Hamburger reports a case in an imbecile boy of four years in whom no parasite was found, though after extirpation of the advancing end it made no further progress. He reviews the literature and the Russian claim of having discovered the larvæ of a fly on the family of the *œstridæ* which, however, has not been discovered elsewhere. The species has not yet been determined. The general symptoms of myiasis are noted and discussed to some extent. He thinks the condition of special dermatologic importance. It remains for future investigation to say whether all such eruptions are the result of the infection of the bot fly, but he thinks there can be little doubt that some dipterous larva is the causal agent.

50. **Papilloma of the Sole.**—Berry reports his own case and the difficulties which he had in treating it by mild or expectant measures. He finally determined to thoroughly eradicate the growth, disregarding the danger of tender cicatrix. After cocainization of the part every vestige of the wart was burned out entirely through the skin of the sole and into the fatty cushion beneath until there was a hole left in which the blunt end of a lead pencil could have been inserted. There was little pain after the cocain wore off and he was able to stay on his feet the next few days. The treatment proved successful. There has been no troublesome scar and no recurrence of the papilloma.

51. **A Bromid Eruption.**—Myers reports the case of a vesicular eruption in a child who had received bromid of potassium in 2 gr. doses every three hours. The eruption was somewhat similar to varicella, but there was no irritation or itching, and the general condition of the child was excellent. The height of the eruption was not reached until ten days after the drug was discontinued. New lesions continued to appear for three weeks. The tongue was involved. She finds nine cases very similar to this reported in the literature, but all the authors considered them of rare occurrence.

52. **Vaccine Virus.**—Foster pleads for a standardized government-regulated manufacture of vaccine virus. When this is brought about the accidents and failures of vaccination will be reduced to a minimum and the prejudices against vaccination will be removed.

53. **Water and Public Health.**—Leighton is the chief of the Division of Hydro-Economics of the United States Geographical Survey, and he gives his opinions as to the relation of water to the public health. Polluted water has little or no relation to the public health, unless it is used for domestic purposes. Water once polluted is unsafe for domestic use, unless artificially purified. The self-purifying power of streams is not constant, and, with the means at hand, can not be determined with exactness. In general, the water of a running stream is not suitable for drinking purposes in its raw state, as in all streams where the flow is sufficient throughout the year to supply any quantity of water directly the drainage area is so large that efficient police regulation would be impracticable. The best water supply is that derived from storage reservoirs or lakes, the drainage areas of which have been cleared of all possible sources of sewage pollution. Even in case of pollution the storage which the water receives is a helpful, though not effectual, safeguard. How the idea that running water purifies itself originated, he says, no one is able to say.

29 *A Sketch of the Past and Future of Embryology. A. C. Eycleshmyer.

29. **Embryology.**—Eycleshmyer's article is a historical sketch of the development of embryology, with a statement of the recent theories and advances. Embryology of the future will have to advance on both morphologic and experimental lines. There is much yet to be known of embryology of the lower vertebrates and of the development of changes in the mammals. As to the human species there are great gaps in our records. There is not extant, he says, a description of a single vertebrate in which the organs and tissues have been followed until they reached the mature condition. We shall some day be able to follow the life-cycle of organs, tissues, cells and structural changes and thus have a basis for the interpretation of structures in disease. Still greater advances are to be hoped for along the lines of experimental embryology and the task for the future lies in the interpretation of the physical and chemical changes, explaining the growth and changes in the organs, etc.

33. **Animal Therapy in Tuberculosis.**—Smith gives a report of the use of lymph prepared from the spermatic fluid of a young bull, which was gathered for a considerable time, and during which the animal was confined and fed on grain to develop the lymphatics. After bleeding the animal to death, the grey cerebral substance, the spinal cord, the gangliæ, the lymph in the reservoirs and ducts and the mesenteric lymphatic glands were taken and with the addition of the semen, the mixture thoroughly triturated in a ball mill with an equal amount by weight of distilled water and half a grain of sublimed albuminate of gold to the ounce, added as a noncoagulant and preservative. The trituration was carried on for ten hours continuously, and after that time, microscopic examination showed the entire disintegration of the spermatozoa, lymphocytes, nerve cells and lymphatics; the emulsion was filtered through a porous filter at high pressure and afterward treated with ether or cold to remove the fats. It was then sterilized by carbonic acid gas under pressure. It is a clear, thick albuminous liquid and a true extract of the organs and secretions stated. Prepared with rigid antisepsis it is hard to contaminate and will keep for months if placed in an amber-colored glass stoppered bottle and kept in a dark, cool place. The compound is injected hypodermically in tuberculosis to the exclusion of all other remedies, preferably in the center and outer parts of the buttocks, subscapular spaces, and along the sides of the spinal column. The injections were given deeply, into the connective tissue, and not into the muscle, and left no induration. The dangers are superficial injections, haste, deficient massage, uncleanliness and too much force in the injection. If there is any pain from the injection, the solution should be dissolved with boiled or distilled water, but it is generally painless and he has had no ill results in thousands of injections. The dosage varies with the individual. In some severe cases he has given as much as ten minims every four to six hours until the severity of the symptoms is abated. Then the periods are lengthened. In other not so acute cases he has had good results from one daily injection of 20 minims. The usual dose is 15 minims night and morning. He insists on a plain nutritious diet, excluding raw fruits as well as vegetables, as they leave much residue. Constipation is generally overcome by the tonic effect of the lymph on the muscular coat of the bowels. It is a cell tonic and reconstructive. The treatment is kept up for three months or longer if it seems advisable. He reports cases of advanced consumption with hemorrhages, cavities, etc., cured by this treatment.

36. **Sarcomata of the Uveal Tract.**—These rare conditions are studied by Parsons, who tabulates and analyzes all the cases he has been able to discover in the literature.

39. **Osmotic Disturbances in Glaucoma.**—Pusey makes the suggestion that variation in the osmotic capacity of fluids may be the cause of some cases of glaucoma. He thinks it seems probable that in varying osmotic pressure (probably a hypertonic condition within the globe) we have the explanation of the primary cause of the condition. Carrying out his experiments to determine this fact in sheep's eyes a striking change was found in the lenses. In certain concentrations of salt and sugar the lense became cataractous. A still more startling experiment was the clearing of the cataractous lenses of the salt solution by putting them in a weak solution of the salt or in distilled water and leaving them there for some hours. He thinks that some interesting fields of study and suggestions as to treatment are opened up in this investigation.

apoplexy. Illustrations of the first two named are given. As regards traumatic neurasthenia he is inclined to think that one thing stands out clearly, the permanent physical and mental incapacity that so often follows concussion of the brain, even after what appears to be an apparently slight injury. He lays particular stress on the minor degrees of mental disturbance, which are easily overlooked and which seriously interfere with the wage-earning capacity of the individual. The possibility of simulation and exaggeration of the symptoms is mentioned. Concussion of the spinal cord is also noted. It may appear immediately or after a few days or weeks, and a number of instances are given. The conclusion he reaches is that though concussion may initiate the development of characteristic signs of tabes it rarely acts as the sole cause of the disease. There are generally symptoms pre-existing which a close observation or study of the literature will reveal. Undoubtedly trauma co-operates with other causes in the production of tabetic disease. The question whether disease of the spinal cord may result from injury to the peripheral nerves is also discussed. He here alludes to arthritic muscular atrophy, a well-known condition. There can be no doubt that morbid impulses from irritated nerves may injure the nutrition of the motor neurons and the occasional muscular atrophy and paralysis become permanent. In conclusion he calls attention to the need for further study of the after-effects of trauma especially as regards their prognosis. There has been much written and said about traumatic hysteria and neurasthenia, but there is room, he thinks, for more recognition of the prolonged and sometimes permanent incapacity for work that may result from concussion of the brain and cord. He believes that the simple prescription of a longer rest in bed after injury would do much to reduce the number of sufferers from chronic nervous disease.

3. **Asylum Dysentery.**—Eyre has studied the occurrence of dysentery epidemics in one of the London county asylums and concludes:

> 1. That a bacillus, identical with the *B. dysenteriæ*, described by Shiga as the specific cause of acute dysentery in Japan, can be isolated from the stools of many cases of asylum dysentery. 2. That the blood serum of some of these cases of asylum dysentery possesses a specific agglutinative action when tested against *B. dysenteriæ* isolated from the stools of other similar cases, and also against other strains of *B. dysenteriæ* isolated from cases of dysentery in tropical countries. On the other hand, the experience of an extended series of examinations of the stools of patients suffering from asylum dysentery will permit me to state: 3. That in order to detect the presence of *B. dysenteriæ*, the stools must be examined when fresh. 4. That postmortem material must be collected and examined as soon after death as possible, as after a few hours' delay, even in quite acute cases, *B. coli* becomes the predominant organism in the intestinal canal. 5. That under these conditions (3 and 4) the isolation of *B. dysenteriæ* from the stools of patients suffering from acute asylum dysentery is comparatively easy by the methods I have indicated [cultures on a modified form of lakmus-lactose-nutrose agar, of Drigalski and Conradi.—Ed.]—when those stools are, naked eye, typically dysenteric. 6. That in cases of chronic asylum dysentery *B dysenteriæ*, if present, is so outnumbered by *B. coli* and other intestinal saprophytes as to render its isolation a matter of extreme difficulty.

4. **Differentiation of the Typhoid and Colon Bacillus.**—According to Stevenson the exposure of a culture on a photographic plate for a short time in a dark room or under red light, when developing a plate, will reveal very marked reduction of silver in cases of the colon bacillus cultures, but very little or nothing with the typhoid germs. The activity of each of these increases with time up to a certain age, say from shortly after inoculation to at least four days of the growth. A colon culture of twenty-four hour age compared with a typhoid culture of any age gives the most marked reducing effect. He has found this discrimination recognizable with four cultures of the colon bacillus from different sources and with five typhoid cultures from different sources. The time of exposure of the plate to the application of the culture has varied between 10 and 90 minutes.

14. **Tissue-Lymph Circulation.**—The extravascular circulation of the body has been studied by Oliver, who points out the effect of the ingestion of food on the tissue-lymph glands. He shows the digestive variations of the blood pressure as revealed by experimental studies, the digestive variations of the blood and in the exudation of tissue lymph. The blood variations clearly show that they indicate striking concurrent events. All four series followed the same curve. He asks what is the link that binds them together. If we suppose that the ingestion of food in some way raises the capillary blood pressure which exudates a filtrate of a portion of the liquor sanguinis into the areolar spaces, all the changes in the blood which he has described will naturally follow. According to the exudation under a rising capillary blood pressure the blood will become more and more concentrated in chromocytes and hemoglobin, and its specific gravity mainly dependent on the corpuscles, its density will rise with increased concentration. Then when the capillary pressure begins to fall, as it does after acme of the digestive disturbance has been attained, the concentration of the blood diminishes, and we may assume that either absorption of the watery elements or the effused lymph overbalances exudation and that the effusion is being returned by the lymphatics to the blood. He has studied the effect of lymphatic pressure aggravated by various kinds of food and of various chemical substances, such as inorganic salts, chlorids and carbonates of sodium, potassium and ammonium, muscle extractives and the active principles contained in beverages. He finds that the purin bodies and alcoholic beverages act as pressor agents. He concludes that the food constituents themselves, proteids, fats and carbohydrates do not possess the power of starting the mechanism by which lymph is dispensed to the tissues, but that nature, however, associates with our foodstuffs small quantities of certain very active substances that do stimulate that mechanism; though they are practically devoid of food value. This natural lymph stimulation is still further increased by the use of salt and beverages containing bodies which act simultaneously to them. These facts, he thinks, demonstrate that such bodies as uric acid, creatin, creatinin, xanthin, glycogen and sodium chlorid perform an important function in nutrition, acting as distributors of lymph to the tissues during digestion. It may be that we will find other substances associated with our food elements possessing this physiologic property. Nature has wisely distributed these active chemicals through most of our foodstuffs and beverages, but man in his efforts to improve on nature often turns these benefactors into malefactors. Besides these lymph factors introduced from without there are supplies of the same material generated within us. It is not improbable that in some subjects the endogenous production of lymph factors may exceed the physiologic average when an adjustment can only be effected by limitation of the exogenous supply.

16. **Eyestrain and Headache.**—Snell takes up this subject, which has been so much discussed by Gould, referring to his recent works. He summarizes his paper under the following conclusions:

> 1. That eyestrain is the cause of a large proportion of headaches, often of a very ag[illegible] 2. That various other neuroses are met wit[illegible] headache, and among these may be mentioned [illegible] tal depression, nausea, indigestion, vomiting. [illegible] choreiform movements of the eyelids and face, etc. 3. That relief is afforded to these conditions by correcting the error of refraction, which can be ascertained only after careful examination. 4. That for such examination a mydriatic is absolutely essential. 5. That frequently no complaint is made of defect of vision. 6. That the ametropia is frequently of low degree, 61.2 per cent. of my cases needing 0.75 D. cyl. and weaker. 7. That a cylinder of 0.25 D. is of great value. 8. That anisometropia is frequently present and requires proper adjustment. 9. That in a certain number of cases the muscle balance is faulty and necessitates the prescribing of prisms.

17. **Muco-Membranous Colitis.**—This condition, from a symptomatic point of view is generally characterized by marked intestinal atony, and more or less abundant secretion of mucoid or membranous matter. *The third fundamental element* of the disease is pain. The treatment as laid down by De Langenhagen consists, first, in alimentary régime. The food should be

chosen as to the nourishment of the patient in such a way that the excrement shall neither be abundant nor irritating. He goes into considerable detail on this subject. What he specially warns against are green vegetables and raw fruits. Very little bread should be taken and that should be stale or toasted. All alcoholic drinks should be avoided. When milk agrees it is generally digested and rarely has to be excluded. All fatty material should be strictly forbidden. All pork, except very lean ham, no game, or crustaceans, hashes, stews, roasts, gravies, sauces and pastry of all kinds. In very severe cases the patient should take nothing but milk if tolerated, light cereal porridges, eggs, beef-tea and sometimes a very little finely minced raw meat. Bread should be strictly forbidden. The second element in the treatment is the washing out of the intestine, which is to be considered as an internal dressing of the mucous membrane. The fountain syringe should be used, the pressure light and the flow slow, so that about ten minutes for a quart injection is required. There should be some softening substance, such as linseed, marshmallow or some medicated substance to render the water less irritating. The temperature should vary from 35 to 48 C. A lower temperature is best where there is a tendency to spasm and resistance, and the higher ones where there is complete atony without spasm, and the physician desires to stimulate the muscular tissue and reawake it, if it is practicable. He would perform this irrigation, beginning with three-quarters of a quart and increase it up to 1½ quarts of the mixture. He prefers to have it in two consecutive procedures, the first to rid the bowel of its fecal contents and the second to carry away the mucus and act on the mucous membrane previously cleansed. The first irrigation should be expelled after one or two minutes, and the second after nine or ten minutes, if possible. But where the patient can secure a good stool before the irrigation he uses but one irrigation and in certain cases also he only performs it two or three times a week instead of once a day. He discusses the objections to it, but claims that they are invalid. The disadvantage of increasing intestinal atony is lessened by the fact that usually things can not be much worse than they are when the process is begun. It is in only about 20 per cent. of the cases that irrigations are useless or cause slight inconvenience, and this may be considered the maximum, according to his statistics. The third element in the treatment is hydromineral cure. He speaks of Plombieres and Chatelguyon springs in France, and describes the methods there used. He does not mention any suitable localities for this treatment in any other countries than France.

18. **Cholecystectomy.**—Moynihan pleads for this operation instead of cholecystotomy. He claims that it is no greater risk, and he is disposed to advocate the frequent, though not invariable, adoption of this operation. It removes the chief source of the disease, and thereby prevents recurrence, growths in the gall bladder or adhesions around it are subsequently impossible, and finally the wound, if drainage is not required, may be caused to heal throughout by first intention. The gall bladder is devoid of any strikingly useful function, and its removal does not make the patient any worse. He describes his method of removal.

19. **Cough in Children.**—Fuller speaks of spasmodic or periodical attacks of coughing and refers to the probability of their being due to adenoids. He thinks the child, if not too weak, should be encouraged to exercise, and a change of air should be recommended when practicable. It may be all that is needed in the majority of cases. Iron when anemia is present, local treatment of the pharynx by gargles, etc., sedatives to relieve extreme reflex irritability and the habit of coughing, and if the bronchi are much affected, the ordinary expectorants are indicated. Adenoids or markedly enlarged tonsils should be removed as soon as possible. Carious teeth should be removed, as they frequently infect the throat.

27. **Disease and Mortality in Military Circles.**—L. Bard is professor of clinical medicine at Geneva, and he does not hesitate to proclaim in the course of this article that the supreme command of an army should be entrusted to a physician when the enemies to be combated are not other men but fevers and epidemics, and the aim sought is to bring the troops to a certain point in the best possible condition for active service. The army physician's place is not in the rear with the lame and the halt; he should be in the very vanguard to select places for encampment, to watch over the sources of the drinking water, to direct the sanitary arrangements in general, matters which are left too often to some heedless second lieutenant.

29. **Abuse of Salt as Cause of Nephritis.**—Tarindo of Modena observed marked aggravation of the nephritis in 2 cases after treatment with saline solutions for a few days. He has also observed the cases of two children who had ingested an immoderate amount of salt, followed by nephritis, the diagnosis in one case confirmed by the postmortem findings. Stokvis, Levi, Castaigne and Rathery have induced lesions of degeneration and inflammation in animals by means of sodium chlorid.

32. **Elastic Intermittent Dilatation.**—Maurat invented three years ago an elastic dilator for treatment of strictures in the urethra or similar organ. A soft elastic sound without any opening at the tip is inserted and filled with water from a graduated syringe. The water is introduced and withdrawn several times in succession, thus accomplishing a soft intermittent dilatation entirely free from friction or pain. He uses a sound with a bulging portion to act on the prostate.

34. **New Local Anesthetic, Stovain.**—The new anesthetic is derived from the group of amino-alcohols, and is the hydrochlorate of amylein alpha beta. De Lapersonne has been testing it in ophthalmology and regards it as an important contribution to the group of local anesthetics. It is much less toxic than cocain. In instillations it does not induce as complete anesthesia, but it is superior to cocain in this respect for subconjunctival and subcutaneous injections. It has vasodilating properties, but this is no inconvenience, owing to its slight toxicity.

35. **Syphilitic Origin of Appendicitis.**—Gaucher states that he found acquired or inherited syphilis in 29 out of 32 cases of appendicitis. Gaucher is professor of dermatology and syphiligraphy at Paris.

36. **Thermo-Diagnosis with Tuberculin.**—Nattan-Larrier admits that the two new diagnostic applications of tuberculin have only theoretical value as yet, but from this point of view they are interesting. Marmorek calls the first the "tuberculin-réaction précoce"; the other is known as the "tuberculin-réac-

tion indirecte." The ordinary reaction to tuberculin is due to the presence of the tubercle, but the "early" reaction is due to the presence of the bacilli. After a few hours they are destroyed by phagocytosis and the reaction can no longer be obtained by this means. The suspected fluid is injected into the guinea-pig and in half an hour 1/80 of a drop of pure tuberculin is injected directly into the brain. In one hour afterward the temperature has risen to a maximum far above that of the controls. Marmorek places the time limit at two to four hours, but Larrier shows that after the first hour the controls' temperature may continue to rise while that of the infected animals subsides. The "indirect" reaction is based on the phenomenon that the ordinary tuberculin test may be induced after inoculation with a tuberculous fluid, before the tuberculosis has really developed, the injection made about the sixth day after inoculation with the suspected fluid. The temperature reaction reached its maximum about the eighth hour in 4, about the tenth hour in 5, and after the twentieth hour in 2. It is thus necessary to take the temperature every three hours during the two days after inoculation. The difficulty of securing identical conditions at each repetition renders this mode of diagnosis impracticable.

37. **Graphic Method.**—Lannelongue applies this term to the systematic drawing on the skin of symmetrical parts the outline of the parts beneath, the recesses, projections, outlines and relations of organs as determined by palpation. Variations from the normal can thus be determined at a glance.

38. **Differentiation of Loops of Small Intestine.**—Bert points out that the valvulæ conniventes of the small intestine diminish in size and number from its commencement to its end. These valves can be palpated through the intestine smoothed between the fingers, and the distance of the part from the duodenum or the cecum can be determined by the size and number of the valve projections felt with the fingers. When pressure is dangerous, as in a distended intestine, the insertion of the valves may be seen through the intestinal wall—at least they can be so seen in the cadaver.

42. **Gelatin and Calcium Salts to Induce Coagulation of Blood.**—Gley and Richaud conclude from the research described that a small amount of calcium salts induces coagulation while a larger amount has the opposite effect. Also that any coagulating action observed after administration of gelatin is due to the proportion of calcium salts in it. Gelatin contains certain substances which actually retard or prevent the coagulation, and when it succeeds as a hemostatic it is due to the fact that it happens to contain the exact proportion of calcium salts needed by the individual. They denounce gelatin on the whole as unfitted for general hemostasis.

43. **Apropos of Decapsulation.**—Tuffier published in 1889 his experiments undertaken to study the possibility of transplanting the kidney. He performed decapsulation and then tied off the renal artery and vein and tried to supplant them by anastomoses on the surface of the organ. He recapitulates his researches here, applying the results observed to Bakes' modification of Edebohls' technic, with the significant statement that all his animals died and also all the animals in similar research undertaken later by Claude.

Semaine Médicale, Paris.

45 (XXIV, No. 16.) *La bactériurie typhoidique et son rôle dans la diffusion de la dothiénentérie. F. Munch (Paris).
46 *Report of German Congress of Surgery. (Commenced in No. 15.) See pages 1175 and 1241.

45. **Typhoid Bacteriuria.**—Munch reviews a number of works on this subject, including several that have been published or summarized in THE JOURNAL, and insists on the prophylaxis. Besides disinfection of the urine as systematically as of the feces, he advises disinfection of bath tubs used by persons who have or have had typhoid recently. Micturition during the bath is of frequent occurrence in typhoid fever. In local treatment of the bacteriuria injections of potassium permanganate into the bladder have resulted in the immediate cure of typhoid bacteriuria in a number of cases on record. He emphasizes especially the enormous number of bacteria liable to be found in the urine and the fact that it does not leave noticeable stains. Urine is evacuated much more frequently and copiously than the bowel dejecta, and is much more intensely infectious and for a much longer period. Ignored contamination from typhoid urine explains many puzzling infections and the contamination of many water supplies. The bacteriuria does not appear to have any influence on the course of the typhoid fever in most cases, although instances have been published in which cystitis persisted after recovery; in Houston's case it developed after three years.

46*a*. **Surgical Treatment of Chronic Colitis.**—Beck has treated 500 cases of chronic colitis during the last seven years, all but 170 being women. The majority had previously been in the hands of charlatans after physicians had diagnosed a neuropathy. He is convinced that the nervous symptoms accompanying the different forms of colitis are purely secondary, the affection of the large intestine being the primary lesion. The etiology generally includes some inflammatory lesion in the abdomen, and in 257 cases he performed some operation addressed to inflammatory lesions outside, and in 19 cases in the large intestine. In 6 cases he performed exclusion of the colon by an ileo-sigmoidostomy with 5 cured to date in this latter group. One patient succumbed to peritonitis attributable to the use of the Murphy button. Surgical intervention was indicated likewise in 120 other cases, but was refused.

46*b*. **New Functional Test of Heart.**—Katzenstein remarks that compression of a large artery, such as the iliac, immediately raises the blood pressure. A normal heart is able to take care of this increased task imposed on it without acceleration of the pulse, but not so in morbid conditions. He tentatively applied compression to both iliac arteries, with simultaneous control of the arterial pressure and of the pulse rate. He found that four classes of responses were obtained: the arterial pressure rose 5 to 15 mm. of mercury while the pulse did not vary; in case of hypertrophy of the left ventricle the pressure increased by 15 to 40 mm.; in the third group the pressure did not vary but the pulse became more rapid, and in the fourth, the arterial pressure sank to a maximum of 30 mm. while the pulse increased in frequency. He thinks that these two latter classes indicate insufficiency of the heart, and advises this simple test as a means to determine the condition of the heart before serious operations.

46*c*. **Cocain in Oily Solutions.**—Klapp's experimental research has shown that cocain in an oily vehicle is absorbed more slowly than when water is used. He thinks that oily solutions are better adapted for spinal cocainization than the aqueous on this account.

packs to the abdomen and brief applications of a cold towel to the abdomen as the patient gets out of a warm bed. No restriction need be placed on the diet except small and frequent meals, and no excess of fluids. Very cold or very hot baths should be avoided in both classes, including prolonged sun baths or electric light baths.

137. **Tumors of the Hypophysis.**—Zak's interest in this subject was aroused by 2 cases that came under his observation, distinguished by the absence of any tendency to acromegaly. In both there was destruction of the hypophysis proper, and he tabulates 25 similar cases from the records. He points out that hyperfunction of the hypophysis seems to induce acromegaly while the disturbances with hypofunction are apparently directly the reverse. He admits, however, that we are not certain as yet as to which elements of the hypophysis are the true functioning ones.

141. **Congenital Morphinism.**—An otherwise healthy girl babe was born to a woman of 36, who had for more than three years averaged 10 cg. of morphin a day, increased to 25 cg. during her pregnancy. The child was restless, and cried constantly, its face showing constant distress and agitation, its arms constantly waving. A swallowing sound in the throat was frequently heard, with attacks resembling spasm of the glottis. Food was taken readily, but vomited at once, and sleep was broken every ten minutes. Half a drop of tincture of opium was then added to 60 gm. of milk and given by gavage and retained. By this means it was possible to quiet the child, and it began to thrive under a brief course of minute doses of opium. It is now a well-developed and intelligent child.

143. **Addison's Disease from Cirrhosis of Suprarenals.**—Munch-Petersen reviews the details of a case personally observed and of 26 he has collected in the literature. The principal features by which atrophy of the suprarenals may be differentiated are the early age and the protracted course of the disease; the alternation of periods of comparative health; the intensity of the terminal attack, suggesting an acute intoxication; the early development of the cutaneous pigmentation; the afebrile course with occasional rises of temperature during exacerbations; the absence of any indications of tuberculosis and also the lack of any palpable tumor below the costal arch and of metastases. In the personal case reported the absence of free HCl suggested gastritis, which was confirmed by the findings later. The age of the patients ranged from 20 to 50 in all but 4 instances and in these the affection had commenced under 10 in 1; under 20 in 2, and at 53 in the other. The duration of the disease was from one to twenty-two years. His own patient was a woman of 44, previously healthy; she died nine months after the first symptoms had been noted. A number of senile changes were noticed in this, as well as in some of the other cases on record, notwithstanding that only one of the patients was over 50.

157. **Cancer in Greenland.**—Bertelsen reports the first case of microscopically diagnosed cancer in Greenland. He has seen 2 others, of whose nature he has no doubt, out of an experience with 950 patients with various affections.

159. **Malignity of Ovarian Tumors.**—Müller urges the immediate removal of all ovarian tumors as soon as diagnosed. In his experience he found the tumor a cyst in 9 out of 47 cases, a cystadenoma in 26, carcinoma in 6 and myosarcoma in 1, with 5 embryomata.

173 *New Method of Sterilizing Milk. Budde. Abstract.

173. **Oxygen Method of Sterilizing Milk.**—Budde's method consists in the addition of about .05 per cent. of hydrogen peroxid to the cold milk, which is then rapidly heated to 52 C. (125 F.) in a covered vessel and kept at this temperature for eight to ten hours. Milk thus treated is effectually sterilized, while its taste is not impaired in the least, and none of its other properties seem to be affected in any way.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Annual Report of the Board of Medical Examiners of Maryland to the Medical and Chirurgical Faculty of Maryland, April 26, 1904. Paper. Pp. 31.

Rhythmic Flashes. By John Mullin Batten, B.E., M.D., Late Acting Assistant Surgeon in the United States Navy. Cloth. Pp 140. Published by the Author. 1904.

Proceedings of the Twenty-Ninth Annual Meeting of the New Jersey Sanitary Association. Held Friday and Saturday, Dec. 4 and 5, 1903, in the Laurel House, Lakewood, N. J. Paper. Pp. 76. Trenton, N. J.: MacCrellish & Quigley. 1904.

Case Technic in Surgery. By Herbert L. Burrell, M.D., Professor of Clinical Surgery, Harvard University, and John Bapst Blake, M.D., Instructor in Surgery, Harvard University. Cloth. Pp. 152 Price, 75 cents. Philadelphia: P. Blakiston's Son & Co. 1904.

A Practical Treatise on Medical Diagnosis for Students and Physicians By John H. Musser, M.D., Professor of Clinical Medicine in the University of Pennsylvania. Fifth Edition, Revised and Enlarged. Illustrated with 395 Wood Cuts and 63 Colored Plates Cloth. Pp. 1213. Price, $6.50. Philadelphia and New York: Lea Brothers & Co. ,1904.

PHYSICAL SIGNS OF PLEURAL EFFUSION.[*]

WILLSON O. BRIDGES, M.D.
Professor of Medicine, University of Nebraska.
OMAHA.

Fourteen years ago I treated a young man with croupous pneumonia of severe though characteristic type. Crisis occurred on the seventh day, but the temperature did not reach the normal. Resolution did not become complete in the solidified area, the cough and expectoration increased, the fever gradually rose to 102, and there was persistence in the dull area with bronchial respiration and subcrepitant râles. He developed night sweats without chills. The expectoration was mucopurulent, occasionally tinged with blood, and in the presence of a family predisposition to tuberculosis, I felt convinced of a development in this direction. For two months there was scarcely any variation in the physical signs of consolidation; he became considerably emaciated, and I was at sea, because repeated microscopic examination failed to reveal the presence of tubercle bacilli in what appeared to be quite characteristic sputum. It then occurred to me to explore the affected area with the needle, when the diagnosis of empyema was at once revealed, an operation performed and my patient went on to complete recovery, and he is still in good health.

Since that time it has been my fortune to meet with at least ten cases in consultation, in which a diagnosis of either pulmonary tuberculosis or chronic pneumonia had been made, where exploration showed neither to exist; and one experience was narrated to me by an undertaker, where, in preparing a body for final disposition, he found the pleural cavity full of pus.

A number of years ago, when attending at St. Joseph's Hospital, a case of heart disease was sent into my ward with a communication that the patient had reached the limit of cardiac compensation and needed to be cared for in a comfortable place until the end. Examination plainly indicated mitral disease, with very feeble heart action, general anasarca and pronounced classical signs of an effusion filling the right pleural cavity. Over three pints of serous fluid were aspirated, prompt relief to orthopnea resulted, and under stimulation cardiac compensation became restored, and the patient left the hospital in a few weeks in a much-improved condition.

About three years ago my attention was called to a young woman in the Methodist Hospital who had stopped there to rest for a few days on her way South from northern Nebraska, where she had been sent on account of supposed pulmonary tuberculosis. On examination she presented the typical signs of pleural effusion, reaching to the third rib on the right side. Nearly two quarts of serofibrinous fluid were slowly aspirated, the lung expanded at once, and during the ten days to two weeks she was kept under subsequent observation, there was no return of the effusion, the lungs were free from indication of involvement, and she returned to her home, instead of going South, a well and much-surprised patient.

Three weeks ago a boy 7 years of age appeared in my office with his parents on their way with him to visit in the country, where they felt a change of air would enable him to better throw off the debilitating effects of whooping cough, which he had last spring. He had not been confined to bed, was thought not to have had fever, but his appetite was not good. He was disinclined to play, and a slight dry cough had persisted most of the time since the whooping cough. He had not been examined by a physician, but the mother had given him various tonics. The father was known to me as having had suspicious tubercular pulmonary trouble, and I requested a thorough examination of the boy. The physical signs were atypical, and I will give them in detail. On inspection, the right side was seen to move less freely than the left, the intercostal spaces were slightly more prominent, the apex of the heart was seen to pulsate an inch and a half to the left of the normal but in the same horizontal line. Litten's phenomenon was absent on the right side. On palpation, distinct vocal fremitus was noted on the right side in areas less marked than the opposite corresponding. On percussion, there was marked dullness over the entire right chest up to the third rib. On auscultation, bronchial respiration and bronchophony were distinct over this area, but perhaps distant somewhat, puerile respiration was noticeable on the left side, and there was no cardiac murmur. The breath sounds over the right lung and the presence of the vocal fremitus with dullness rather than flatness, were suggestive of consolidation or tumor involvement of the lung. The displacement of the heart apex in the absence of a murmur and kidney disease and the fullness of the intercostal spaces were suspicious signs of an effusion. The history was toward an effusion. The aspirating needle was introduced in the seventh space in the axillary line, and three pints of serofibrinous fluid withdrawn. The lung expanded promptly, the heart apex resumed its normal position, and during the ensuing week there was no return of the fluid.

DEDUCTIONS FROM CASE REPORTS.

These cases illustrate two points which I wish to make: First, that cases of pleural effusion may present atypical physical signs, which are misleading; and, second, that in quite a proportion of cases, the chest is not sufficiently examined by the attending or consulting physician, and consequently the lesion escapes detection. Effusions in the pleural cavity may be inflammatory or non-inflammatory. The inflammatory are serofibrinous, seropurulent, and may be hemorrhagic. They arise from pleurisy, acute or chronic, pleuropneumonia, pulmonary tuberculosis, pericarditis, and as complications of the infections. The non-inflammatory are cases of so-called hydrothorax, and result from interference with the circulation, as in organic heart disease, venous thrombosis within the chest cavity, chronic pulmonary disease, intrathoracic tumors, and also from chronic Bright's disease, diabetes and the dyscrasiæ. The physical signs are usually similar in both classes, but they are less apt to be typical in the inflammatory, for here great thickening of the pleura, localized adhesions, the existence of pulmonary consolidation, communication with a bronchus (pathologic states which may exist) interfere with the production of conditions on which the typical signs are based. Then, too, the signs will vary somewhat, according to amount of effusion within the cavity. It is stated that at least a pint must be present in order that it may be detected, and from this amount to a full cavity, which will exert displacement of adjoining organs to the maximum, great variation must be expected.

---

[*] Read before the Burt County Medical Society at Oakland, Neb.

It is not my purpose to go over all the detailed textbook physical signs of pleural effusion, but rather to call attention to two signs not found in most text-books, and to point out variations from the typical, which I believe are more common than we were taught, and consequently responsible for many errors by those who are inclined to hard and fast rules.

THE INTERCOSTAL PHONATION PHENOMENON.

On inspecting the normal chest in other than the obese, it will be noticed that when the person observed speaks short words, or syllables, there is distinct elevation of the intercostal spaces. This is more distinctly seen where the spaces are widest in the lower latero-anterior part of the chest. The phenomenon was first described by Weiz. and is suggested as a recent diagnostic sign by Stiller. It results from wave currents of air, which are sent in all directions down the bronchial tree during phonation when the glottis is narrowed, and carried to the lung substance adjacent to the intercostal spaces where bulging is produced. Abrams states that the phenomenon is intensified if the patient closes the nostrils and covers the mouth during phonation. According to Stiller, this phenomena enables one to clearly indicate the boundary line between the lungs and liver or spleen, and to differentiate between a pleural effusion and solidified lung or tumor. If fluid exists in the pleural cavity, the increased pressure in the adjacent lung during the act of phonation results in waves being communicated to the fluid which bulges the intercostal spaces. In consolidation of lung contiguous to the chest wall, this could not occur. The objection offered to this sign is that it is not observable in obese persons.

THE PHRENIC SHADOW TEST.

The Litten phenomenon was first suggested in 1892 by Litten, and is a phrenic shadow, normally seen under proper relations of light to the chest wall. To elicit it, place the patient in the recumbent position with the chest and upper abdomen bared, and the feet toward a window or other strong light. Cut off all side and cross lights. The observer, now with his back to the window and beside the patient, may notice that with each deep act of inspiration, a narrow shadow starting at the anterior axillary line and seventh rib descends obliquely forward to cross the seventh, eighth and ninth ribs, and to recede with less distinctness during each act of expiration. It is equally noticeable on the two sides, and occasionally in the epigastrium. This shadow phenomenon simply represents a receding of the diaphragm from the ribs during inspiration. It is invariably manifest in health, but is more pronounced in thin persons and those who can take deep inspirations. Its presence signifies normal relation of the lung and diaphragm to the chest wall and normal function. Its absence signifies the opposite. Its absence, therefore, is a marked physical sign of pleural effusion, and is noted as soon as there is sufficient fluid in the cavity to alter the normal relation between the lung and diaphragm and the chest wall. Taken in connection with the intercostal phonation phenomenon, we have a valuable combination of physical signs to aid us in differentiating between pleural effusion and pneumonia.

HEART DISPLACEMENT.

Displacement of the heart occurs in pleural effusion of any magnitude, away from the affected side, but in suspected right-sided effusions we must rule out hypertrophy of the left ventricle as a factor in the abnormal location of the apex and in suspected left-sided effusions hypertrophy of the right ventricle. We are aided materially, of course, by excluding any cause for hypertrophy as valvular murmurs, chronic Bright's disease, hepatic cirrhosis, arteriosclerosis, etc. An error may result in the interpretation of a displaced apex to the left, which is not above its normal transverse line, but it is to be remembered that the whole heart may be displaced by a large effusion, and not only its apex. When the apex only is displaced to the left, it is located at a higher point than the normal.

VOCAL FREMITUS.

We are taught that the absence of vocal fremitus is the rule over large effusions, and that it is very much enfeebled or lessened in smaller ones. It should be remembered in this connection that the voice vibrations are more pronouncedly felt, as a rule, over the right chest in health, and that in case of suspected effusions in the left cavity, a *diminished vocal fremitus* on the affected side would be of less significance. This sign is directly affected by the strength and pitch of the voice, and is of greater value in men than women, and least of all in children. In fact, vocal fremitus may be pronounced over a large effusion in children, as was stated in my last case reported above, and I have several times noted it over purulent effusions complicating or following pneumonia. The explanation for this exception is a supposed transmission of the voice vibrations from the lung along pleural bands of adhesion to the chest wall or from the sound side by means of the chest wall itself. These exceptional cases are very confusing.

PERCUSSION.

The percussion note over pleural effusion will vary materially according to the amount of the fluid present. The first dullness is noticed at the posterior base, and as the fluid increases it becomes more marked. When the level of the fluid has reached the fourth rib in front, the percussion signs are characteristic. There is dullness below the level of the effusion, progressing to absolute flatness toward the base. Above the fluid will be noticed Skoda's tympanitic note. With the patient in a semi-reclining position this sign is marked in the infraclavicular region, and is important. When the patient is erect, the upper line of dullness is not level, but is higher behind and to the side than in front, forming an irregular parabolic curve. This is most pronounced in medium effusions. In very large ones the curve becomes obliterated.

Alterations in the location of dullness with the change of posture is more noticeable also in moderate accumulations, and is often absent in effusions complicating or following pneumonia on account of pleuritic adhesions. When seeking for alterations in dullness, it is to be remembered that the fluid gravitates slowly with the change of posture of the patient and too quick comparison is to be avoided. In right-sided effusions the liver dullness may extend far below the normal and in left pleural effusions the semilunar space of Traube gives up its tympanitic note to flatness.

AUSCULTATION.

As the fluid accumulates the breath sounds grow feeble and distant; normal respiration often gives way to indistinct bronchovesicular, which is followed by bronchial breathing. Above the level of the fluid the breathing is bronchovesicular. In these cases there may be bronchophony, and this combination of auscultatory signs in small or medium effusions are often apt to lead one away from pleural effusion, especially so in children, where they are most commonly found. The bronchial breathing of pleural effusion differs somewhat from that over consolidation in seeming to be more distant and less distinct. In large effusions the signs on auscultation vary with the degree of compression of the lung. In these the breath sounds entirely disappear, with the exception of bronchial respiration, which is heard over a limited area in the interscapular region corresponding to the compressed lung. Baccelli pointed out that the whispered voice is sometimes transmitted through a serous effusion, but not heard through pus. Moist râles are exceptionally heard over an effusion, and are said to be usually of bronchial origin. I have observed them more in cases of purulent effusion communicating with a bronchus.

EXPLORATION.

In suspected cases of pleural effusion in which, owing to the atypical physical signs, definite conclusions can not be reached, the resort to the exploring needle when properly selected clears up the uncertainty. Such cases are more apt to be of the inflammatory type complicating or following pneumonia, and not infrequently are localized effusions, in which the greatest care is needed to properly find the limitations of the area in which physical signs may be found.

In my experience none but the largest needle of the aspirating cases should be used for exploration, excepting, possibly, in suspected hydrothorax, and even here the largest is the most to be depended on. I have been disappointed a number of times not to find fluid even with the largest needle, where fluid existed, and I recall a case seen within the year in which, after two unsuccessful attempts with the large needle, I was so satisfied of the existence of fluid from the history plus atypical signs that I introduced a good-sized trocar and canula at the point of needling, and a serofibrinous effusion was immediately demonstrated.

THE PREVENTION OF TYPHOID FEVER.

RUFUS I. COLE, M.D.
Instructor in Medicine, Johns Hopkins University; Assistant Resident Physician, Johns Hopkins Hospital.
BALTIMORE.

To infected water have been attributed the approximately 200,000 cases of typhoid fever which occur each year in this country. But it is the old story of the innocent blamed while the guilty escape.

It required almost three centuries of fighting, from Francisco Redi to Pasteur, before the theory of spontaneous generation could be overthrown. To-day, though the proof is certain that only from one case of typhoid is another begotten, we close our eyes to the truth, and go on acting as though water were the source of all typhoid infection.

To stamp out typhoid fever, in the absence of any specific treatment, requires (1) the recognition of all cases, and (2) the destruction of all typhoid bacilli as they leave the patient. The process need not even be so complete; *most* may be substituted for *all.* Though the water supply contain as much sewage as Chicago River, or be as foul as Jones' Falls, if no typhoid bacilli get into it it can not cause typhoid fever. We hear so much of the association of typhoid fever and water that we almost come to believe that it is their natural habitat, that it must be a war of expulsion. As a matter of fact, while typhoid bacilli may live for a considerable time in water, they do not thrive there, and under ordinary circumstances die out within a comparatively short time. I realize fully that this is a general statement to which some may raise objection. It is impossible in this paper to go into all the evidence on this question. Whether typhoid bacilli may live two weeks or two months, or even longer, in water, is immaterial. It can not be proved that outside of the body, under ordinary circumstances, typhoid bacilli thrive and multiply.

It is also probable, as Dr. Welch has pointed out, that the infectiousness of water or any infected material is directly proportional to the number of typhoid bacilli it contains. It can not be supposed that every one who takes typhoid bacilli into his stomach will develop typhoid fever. Not long ago I had fairly good proof of this. A new laboratory janitor, in spite of careful instructions and warnings, was found to be washing tubes containing typhoid bacilli before sterilizing them, in order to lessen his labors. He had done this for two days before he was discovered. His hands must have been covered by millions of typhoid bacilli, and while eating, and in other ways, he must have conveyed many to his mouth.

For infection to occur in typhoid fever, probably two conditions must be present: first, a lowered resistance on the part of the patient, and second, a sufficient number of infecting organisms. With a disease like typhoid fever, in which the strongest and healthiest are attacked, it is difficult to determine the factors which cause this lowered resistance. Some have said that sudden overexertion may reduce the resistance of the strong and healthy. But the proof rests only in isolated observations and is not sufficient. Possibly chance may play a part, slight injuries to the intestinal mucosa being required. The work of Dr. Ravenel, showing that tubercle bacilli may pass through the intact intestinal mucous membrane and enter the lymphatic channels, is evidence against this view.

But however this may be, for the bacilli to enter in sufficient numbers to cause infection they must wage a strong battle from the time they leave one patient until they enter the next. They must battle with cold, with sunshine, struggle with millions of opponents, and then run a very slight chance of entering susceptible subjects. The vast majority must die.

But suppose from a given patient a million bacilli enter the uncontaminated general water supply each day. With the great dilution and factors unfavorable to the life of the bacilli there is only a chance that one person may be infected. One person becoming infected, if the bacilli from this one are destroyed before they enter the water supply, the chances of others becoming infected are no greater than they were before, and possibly no further cases will occur. But, if a second million of bacilli from this patient are also allowed to daily enter the water supply, the chances for further infection are twice as great. Instead of a possibility of one infection occurring, there is a possibility of two. Again this infection occurs, and if no precautions are taken the chances become four times as great. Thus the chances multiply by geometrical proportion—and the epidemic is started.

There are three ways to prevent the second infection: First, have a water supply from such a source and so guarded that it is impossible for the bacteria to enter it. Second, sterilize all water before it is consumed by the public. Third (and this is the one that it has taken the members of the medical profession longest to recognize), destroy all bacilli as soon as they leave the patient.

That a very small proportion of the cities and towns of this country have a water supply inaccessible to contamination, the widespread prevalence of typhoid fever testifies. To remove bacilli from water requires either expensive filtration plants, which are notoriously uncertain, or compelling all people to boil the water before using. In America to compel is difficult. The third way is the way open to the physician, and here we have neglected an opportunity and our duty.

The advantage of a good clean water supply can not be overestimated, but this is valuable entirely apart from the question of typhoid fever. So long as typhoid bacilli are being scattered about and any possible source of contamination for a water supply exists, however pure the water may be, the danger of infection and of epidemics is not removed. In ultimately preventing and stamping out this great plague in this country, other measures are necessary beside the obtaining of a fair water supply for our cities. In Chicago it is estimated that $36,000,000 have already been spent in the attempt to obtain a good water supply. There is still the opportunity for contamination by the sewage from a vast area of the city, and it is calculated that the expenditure of $32,000,000 more will be necessary before the water may be considered safe.[1] With the interest on this vast amount of money almost the air from each patient could be sterilized!

Let us now leave out of consideration the conditions in the cities, where the water supply is directly under public control, and consider the conditions in the country. In the paper of Dr. Fulton, the overwhelming evidence is adduced that typhoid fever exists to a proportionately greater extent in the country than it does in the city, and that the propagation of this disease is in general from the country to the town, and not from the town to the country. In Baltimore, in the Johns Hopkins Hospital at least, we are in the habit of inquiring of the patients (if they are not admitted from the suburban villages, as many of them are) when they were last in the country and where they drank water there. In the water supply of a large city the chances for dilution of the contaminating fluids is so much greater than in the country, where the privy vault is often in such close proximity to the well.

But through the water is not the only way in which the typhoid infection is spread. Some maintain that it is not the most common way. They insist that the ultimate proof must rest with the demonstration of the typhoid bacillus in the water. As is well known, this is difficult. One writer during the past year claimed that there has been undoubted proof of the occurrence of typhoid bacilli in drinking water only six times. This demonstration, however, is not necessary. There is ample proof on epidemiologic grounds that typhoid bacilli are most frequently transmitted from one patient to another through water. The proof is just as good that other methods play an important though not so frequent rôle. There is undoubted evidence that the bacilli may be carried by milk, oysters, uncooked vegetables, etc. Great stress has been laid on the probability of flies carrying the infection. Many cases undoubtedly arise by direct infection. Within the past few months there have been five members of one family treated in this hospital for typhoid fever. There are no other cases in the neighborhood of their home, and they had all been drinking city water. Certainly these can not all be cases of water infection.

From all this it is evident that we can not depend on water purification alone to stamp out this disease. Other measures are necessary, and it is the duty of the physicians to set these other procedures in operation.

It has been insisted on by many writers that the first essential in prophylaxis is correct diagnosis. Ever since the Spanish-American War and the exposure of the mistakes made in the diagnosis of typhoid fever, it has been the fashion to heap abuse on the physicians of this country for failure to recognize this disease. No doubt the condition is bad enough, and probably faulty teaching is to blame. But conditions are improving. Possibly one of the most valuable results of the war was this lesson to the physicians. The perfection of bacteriologic methods, the methods of cultivating the bacilli from the blood and stools, the Widal test, have made possible the making of a positive diagnosis in every case, and there can be no doubt that these methods should be employed much more generally than they are at present. Especially is this true on account of the importance of exact diagnosis with regard to prophylaxis. One of the most common mistakes is the failure to recognize typhoid fever in children.

But it is not necessary to wait for exact positive diagnosis before instituting prophylactic measures. Dr. Osler has said that, north of Mason and Dixon's line, every continued fever, not yielding to quinin in six or seven days, should be considered typhoid, until definitely ascertained to be something else. For prophylaxis it is better to go a step farther, and not wait for six or seven days, but, both above and below Mason and Dixon's line, whenever there is a suspicion that typhoid fever is present, prophylactic measures should be inaugurated. These measures do not cause any great hardships. They may cause some slight inconvenience, but so do all preventive measures. Does general vaccination cause no inconvenience? Does the retention of a great ship full of people at quarantine, because there is one case of smallpox aboard, result in no discomfort? The inconvenience and discomfort entailed in combating typhoid is not to be compared with that necessary in stamping out most of the infectious diseases.

---

[1] Jordan: The Journal A. M. A., vol. xxxix, p. 1561.

There is no doubt that there should be much greater care in the diagnosis. Even though at present one-half the cases are not recognized, that does not lessen the responsibilities of the physicians who do make proper diagnoses. It is probable that three-fourths of the cases, at least, are treated by physicians, and in three-fourths of these there is a suspicion that typhoid fever is present, even though a positive diagnosis is made in only one-half or even fewer of the cases. If we were honest and fearless enough to start prophylactic measures as soon as the suspicion arises, over one-half of all cases could be prevented from doing harm to others. But, whatever the proportion, the danger in a community is directly proportional to the number of cases existing. Possibly one case may infect a city, but in general it is not so. It is not only the great epidemics that need to be combated, but the cases occurring in succession. In a large part of this country typhoid fever never dies out. Even in the great epidemics the onset is usually not sudden. One case begets another; there is no spontaneous generation.

We are so in the habit of calling the kettle black; we complain so much about mistaken diagnoses that we neglect prophylaxis in the cases where we have made a diagnosis, or above all, in those in which we have only suspicions. Perhaps it is beyond the range of possibility to recognize every case; the best clinicians occasionally make the diagnosis on the autopsy table. Other cases, too, walk about and never consult a physician. But with proper prophylaxis in the recognized cases, cases will become fewer and fewer, and at the same time the atypical cases will become more rare. Even though some cases escape recognition, it does not seem too much to hope that the disease may ultimately be stamped out from any community and from the country.

There is much talk of the necessity of control by the health boards, for notification laws. This will be of the greatest value in controlling the black sheep of the profession who fail to do their duty. We trust and believe they are few. The physicians of the country should not need to be compelled to do that which is so obviously for the benefit of the community. At any rate, they should be the ones to inaugurate the reforms. We have waited long for the health boards to obtain the necessary authority. The active reform on the part of the physicians will aid in bringing the necessary legislation about. But the procedures necessary are not those which would be easy to compel the people to carry out. What the government never can do, the attending physician can accomplish by proper instruction, advice and directions.

What are the necessary procedures? Simply sterilize the excretions as they leave the patient. In what other infectious disease is the prophylaxis so simple and the means so readily within our power? Compared with tuberculosis or the exanthemata, the difficulties melt into insignificance. Nevertheless, although we know the cause of this disease, we know how this agent leaves the body, we know that its destruction at once will prevent other cases, yet, because those in the immediate surroundings of the patient are not ordinarily directly affected, we are apathetic. But the persons in the immediate environment are in danger—not so great as with the exanthemata—but still in danger of infection, and this fact should be more strongly impressed on students and on the public. The constant teaching that typhoid fever is infectious, but not contagious, has tended to cause students to play with words and overlook the real conditions. Of course the greatest danger of a typhoid patient is to the community at large, and, since that is so, the family of a patient must be urged to exert themselves. If a case of scarlet fever occur in a house, the whole house is disarranged, an isolation hospital is improvised, the food is passed in to the nurse through an outside window; the greatest precautions are observed. But with typhoid all is different. "It is infectious, but not contagious"! The discharges loaded with typhoid bacilli are thrown into the sewer, to be carried possibly back to the water supply, or they are thrown into the privy vault to pass into the nearby well. The urine may be thrown on the ground to contaminate all it touches. The soiled bedclothes contaminated by feces are handled by a half dozen persons before they reach the laundry. The nurse's hands are contaminated by urine and feces, and the bacilli are widely distributed. When one considers the chances for infection the wonder becomes that typhoid is not more prevalent.

The carelessness and apparent ignorance of physicians and students in regard to this is surprising. Students who work with typhoid bacilli in the bacteriologic courses will take every precaution in case a drop of pure culture of typhoid bacilli gets on the hands or furniture. But when this student comes into the hospital wards or treats a case of typhoid fever, he will, in examining the urine, spill it over his hands and over the floor and never think of taking proper measures for disinfection. Notwithstanding all that has been written on the presence of typhoid bacilli in the urine, students have not yet realized the truth.

I have made cultures from the urine during the past few years, and in about one-third of the cases typhoid bacilli have been cultivated. Other observers have found them present in from 20 to 35 per cent. of the cases. Sometimes they are in enormous numbers. Horton-Smith estimated in one case 500,000,000 per cubic centimeter. Not infrequently they can be seen by the naked eye; that is, when a test tube containing the urine is held up to the light a turbidity and shimmer is seen, which is entirely due to the suspended bacilli, and is similar to that seen in bouillon cultures or suspension of the bacilli. In the majority of cases the bacilli in the urine give rise to no bladder symptoms; the condition is a bacilluria, not a cystitis. The bacilli may appear in the urine at any period of the disease, usually, however, not before the second or third week. They may be present only for a few days, and then disappear, or they may be present during the entire course of the disease. Usually they disappear spontaneously during the first or second week of convalescence, though in rare cases they may remain longer. In the individual case it is not necessary that their presence should be demonstrated before beginning prophylactic measures; there would be very great risks in waiting for such a demonstration. The urine of every case of typhoid must be disinfected as soon as it is voided.

The second way in which typhoid bacilli leave the patient is in the feces. With newer and better methods of cultivating typhoid bacilli from the stools, it has been shown that in a majority of cases the bacilli do not appear in the stools before the beginning of the second week, and disappear with the fall of the fever.

That they may appear earlier and may persist into convalescence, even longer in rare cases, can not be doubted, yet these exceptions may be disregarded. There is also proof that typhoid bacilli in small numbers may occasionally occur in the stools of the doctors and nurses caring for typhoid-fever patients. However, this is probably a very rare occurrence, and, with greater care and cleanliness on the part of the attendants, this need not occur.

There have been a number of cases reported in which typhoid bacilli are said to have been present in the sputum. In a number of these cases the proof that they were typhoid bacilli is unsatisfactory. In the small number of cases where the evidence is convincing there was a pulmonary complication present, and the sputum in most cases was bloody, and the presence of the bacilli may have been in association with the blood.

Reports have also been made of the discovery of typhoid bacilli in the sweat and even in the expired air. In all such reports that I have been able to find the proof has been entirely unsatisfactory.

From the standpoint of prophylaxis, the question practically narrows down to disinfection of the urine, stools, sputum (in the few cases where such is present), and of all the objects which may accidentally be contaminated by these excretions.

DISINFECTION OF THE URINE.

The nurse or attendant should be taught to regard every specimen of urine as a pure culture of typhoid bacilli, and to exercise the greatest care in preventing the scattering of drops of urine over the patient, bedding or floor, or over the hands of the attendant. The question as to the best solution to use for disinfecting the urine has been carefully studied by Gwyn.[2] He found that for disinfection of the urine within one-half to one hour, a volume of urine would require:

3/10 to 4/10 its volume of 1-20 carbolic acid solution.
1/40 of its volume 1-1,000 $HgCl_2$ solution.
1/10 of its volume 10 per cent. formalin solution.
1/10 of its volume liquid chlorids.

For disinfection within one to two hours, a volume of urine would require an equal volume, to one-half its volume, of milk of lime solution. A volume of urine may be disinfected within five to fifteen minutes by one-fortieth its volume of chlorinated lime solution.

As to the relative value of these disinfectants, he concludes:

> Milk of lime hardly deserves the name of a disinfectant. Carbolic acid is of use only in large amounts, and in strong solutions, if a speedy result is wished. Formalin is hardly serviceable on account of its cost, but is nevertheless an efficient disinfectant. Bichlorid of mercury, chlorinated lime and liquid chlorids are of real value, are rapid in their action, and are efficient in comparatively dilute solutions.

My own experience with chlorinated lime leads me to believe that it is neither the safest nor the best disinfectant to use for the urine. Although strong solutions of carbolic acid are required, they are efficient, not expensive, and, except for the poisonous properties, very suitable for this purpose. The solutions of bichlorid of mercury are also good, and I should advise these two substances in preference to the others. In making the $HgCl_2$ solution, it is well to add $NaCl$ in the proportion of 0.5 parts to 1,000.

The best plan is to have a covered jar containing 1½ liters of 1-20 carbolic acid solution, or 200 c.c. of 1-1000 $HgCl_2$ solution, preferably the latter. Into this jar the urine can be poured from the urinal as soon as it is voided, and the jar should be emptied every day, but not sooner than one to two hours after the last urine has been added. These amounts of fluid are sufficient to sterilize 3 liters of urine. If more is being voided the amount of disinfecting solution should be correspondingly increased. A second jar large enough to contain the urinal should also be filled with the disinfecting solution, and in this the urinal should be allowed to remain constantly, except when required for the patient's use.

A very important question is as to the length of time necessary to continue the sterilization of the urine during and following convalescence. As previously stated, in most cases the bacilli disappear from the urine during the first or second week of convalescence, but they may persist much longer, even for months, or in rare cases, for years. These cases, however, are usually associated with symptoms of inflammation of the urinary tract, and are so discovered, when extraordinary measures should be used to prevent the condition from continuing. So long as the symptoms are present sterilization of the urine should be persisted in. In hospitals, or wherever bacteriologic methods are available, no patients should be discharged until cultures from the urine show typhoid bacilli to be absent. Whenever such methods are not available, the patient should be urged to continue the sterilization of his urine into the third week of convalescence. Practically, it will hardly be possible to have this done longer.

By a number of writers the administration of urotropin as a prophylactic measure has been urged. The evidence now is pretty conclusive that urotropin does not kill the bacteria, which have gained entrance to the urinary tract, but only inhibits their growth. Therefore, according to Fuchs,[3] although when bacilluria is already present, urotropin apparently causes disappearance of the bacilli from the urine, they may reappear as soon as the urotropin is discontinued. On the other hand, if the urotropin is begun as early as possible in the course of the disease, it may prevent the occurrence of a bacilluria. The dose should be 2 gm. (30 gr.) daily, best given as gr. x, three times a day. However, several cases of hematuria following the administration of urotropin have been reported, in one case after giving the above dose for seven days. I know of no case, however, in which there has been any permanent damage to the kidneys.

Under no circumstances does the administration of urotropin permit the disinfection of the urine to be neglected. Such disinfection should be prolonged as far into convalescence as possible. When possible the urine should be shown to be free of bacilli before the patient is discharged. If urotropin is administered it should be begun early and continued throughout the course of the disease.

DISINFECTION OF THE STOOLS.

The determination of the best method to be employed for this purpose is much more difficult than in the case of the urine, since frequently the bacteria are imbedded in a hard firm mass of feces, which renders difficult the action of the disinfecting solution. The solutions most generally employed for this purpose are chlorid of lime, carbolic acid and milk of lime. Bichlorid of mercury is not a suitable medium. Good chlorid of lime is very suitable, but unfortunately it sometimes happens that the commercial product is not good. I have found one specimen purchased for this purpose to be absolutely worthless. One can not afford to take any risks in disinfection of the stools.

---

[2] Johns Hopkins Hospital Reports, vol. viii.

[3] Deutches Archiv f. klin. Med., vol. lxxvi.

Both milk of lime and carbolic acid have been found to be efficient in case certain precautions are observed. I have tested these two solutions in the following way, imitating as nearly as possible, the natural conditions: A given weight of semisolid feces was sterilized, then thoroughly mixed with a given amount of typhoid bouillon culture and placed in the incubator for several hours, with the hope that the bacilli would penetrate somewhat into the fecal masses. The disinfecting solutions were then added and allowed to remain for a given length of time. The mixture was then diluted with a large amount of sterile water to get rid of the action of the disinfection solution and cultures made from the sediment obtained after standing a short time, or after centrifugalization. Carbolic acid was found to be very satisfactory, a given volume of feces being disinfected in one-half hour by an equal volume of 1-20 carbolic acid solution if the two are thoroughly mixed together.

It was found that by mixing a given amount of feces infected with typhoid bacilli with three times its volume of milk of lime, no bacteria could be demonstrated after one hour, even though the sediment were thoroughly washed with distilled water, and then the entire sediment added to a large amount of bouillon. The objection to the use of milk of lime is that too often it is not prepared in the right way. Air-slaked lime is worthless. To be of use the lime should have been freshly burnt and should be mixed with water in the proportion of 100 parts of lime to 60 of water. The lime should be allowed to soak up the water slowly. The dry hydrate which results may be kept for some time, but when exposed to the air also quickly takes up CO_2 and becomes worthless. To prepare the milk of lime, one mixes one part by weight of the fresh dry hydrate, prepared as advised above, with eight parts by weight of water. This mixture should be prepared fresh daily.

In using milk of lime to disinfect feces, it is necessary that they should be thoroughly stirred together, and if there are hard fecal masses the fluid should be allowed to act for a long time, even an entire day. As in the case of the urine, it is well to have a jar to hold the feces for the entire day. The milk of lime should be poured over the feces in the bedpan and the mixture thrown into the jar and covered by an excess of the milk of lime and all thoroughly stirred together with a stick or rod kept for the purpose. The bedpan should be kept filled with milk of lime when it is not in use.

Considerable attention has been given to the details of the disinfection of the stools and urine, because it is believed that at present, even where attempts are being made to carry out disinfection, absolutely no results are being obtained. One might as well make no attempt to disinfect the stools as to do as is often done, simply pour over them a little milk of lime, which has been prepared for weeks, and during this time has stood exposed to the air.

On account of the care necessary in preparing and keeping the milk of lime solution, disinfection with carbolic acid is in general to be advised. It is not an ideal disinfectant on account of its poisonous properties, but I believe at present it is the best available. It is cheap and quite efficient when used in strong solutions. To avoid any risks it is better to use stronger solutions than were found to be efficient experimentally. I should advise thoroughly mixing the stool with at least twice its volume of 1 to 20 carbolic acid solution and allowing it to stand for several hours, at least.

The ideal method for sterilization of the feces is by heat, and this method has been employed to some extent by the English army in South Africa. The stools were boiled in large cauldrons with a small amount of carbolic acid added, which entirely destroyed the odor. By this method the feces were rendered harmless almost instantly. The method is described by Major Cummings.[4] Such a method as this should be employed in fever hospitals and military camps, or wherever large numbers of typhoid-fever patients are collected. The method, however, could hardly be employed for individual cases. After a stool the patient's buttocks should be wiped with a solution of $Hg\ Cl_2$ 1-1,000. The patient should be urged to carry out the disinfection of stools during entire convalescence.

DISINFECTION OF THE BATH WATER.

Undoubtedly the general employment of hydrotherapy in treating typhoid fever has added another important channel by which typhoid bacilli are disseminated, and yet practically no attention has been directed to this danger. The patients occasionally void in the bath, and there is always the danger of small fecal particles being washed from the anus into the bath water. This contaminated water is usually thrown into the common sewer. Where portable bath tubs are used it is not infrequently splashed over the floors. E. Babucke[5] has sought experimentally to find the best method for the disinfection of the bath water. He found chlorid of lime the best substance to use, and found that even where the water contains coarse fecal matter, 250 gm. (one-half pound) of chlorid of lime will render the ordinary bath of 200 liters sterile in one-half hour.

As previously stated the quality of chlorid of lime is unfortunately somewhat uncertain. However, at present I know of no satisfactory substitute for this purpose. It is well known that the disinfecting properties of chlorid of lime depend on the active chlorin it contains, and this is rapidly lost on exposure to the air. It is of importance that it should be purchased in small tightly closed packages; the cans with sliding tops are not sufficiently tight. When a can is once opened its contents should be used quickly, better within one to two days. If this substance is purchased in such tight one-half pound packages, thus containing enough for only two to four baths, it will be found a very suitable and effective medium. Fortunately the tubs are not injured by it.

OTHER PROCEDURES IN DISINFECTION.

If there be any expectoration, the sputum should receive the same care as in tuberculosis. It is best to collect it in small cloths, which may be burned.

All the linen leaving the patient's bed or person should be soaked for two hours in 1-20 carbolic acid solution, and then sent to the laundry, where they should be boiled. All dishes should be boiled before leaving the patient's room.

The nurse should wear a rubber apron when giving tubs or working over a typhoid patient, and this should be washed frequently with a carbolic acid or bichlorid of mercury solution. The nurse should wear rubber gloves when giving tubs, or else soak her hands thoroughly in 1-1,000 bichlorid solution after she has finished.

[5] Centralblatt f. Bakteriologie u. Infectionskrankheiten, 1900, vol. xxvii, p. 800.

It is impossible here to deal with all the possible modes of spread of the infection. Keeping in mind that everything leaving the patient should be sterilized whenever there is a chance of its having been contaminated by the discharges, any physician, assisted by a nurse of ordinary intelligence, even one of the family, can carry out very satisfactory prophylaxis.

ISOLATION OF PATIENT.

The question as to the necessity for the isolation of typhoid fever patients is a difficult one. To prevent direct infection of the other members of the family a moderate degree of isolation should be carried out, though this need not be absolute as is necessary in the exanthemata. The windows should have fly screens in summer. After recovery the room should be disinfected. There can be no doubt as to the advantage, not only to the patient, but to the public at large, of the treatment of typhoid-fever patients in hospitals. This is especially true where the patient's circumstances will not permit satisfactory prophylaxis to be carried out at home. Usually in the cities such patients can now be prevailed on to enter hospitals, but in rural districts this is impossible. Here the health boards should be appealed to for means to carry out satisfactory isolation and prophylaxis. The country health boards must learn to recognize that this is as important as isolation in smallpox, though not nearly so difficult to perform.

An important question is as to the necessity for the isolation of typhoid patients in special wards in hospitals. At present this is not generally done in this country. It is more frequently done in Germany, yet so eminent an authority as Professor Curschmann thinks that it is unnecessary in carefully conducted hospitals. Every one, however, who has had experience in general hospitals. knows that cases of hospital infection are not uncommon. Many such cases are reported in the literature, yet for obvious reasons, very few statistics in regard to this point are available. When, however, in a hospital with as good sanitary arrangements as the Johns Hopkins possesses, and in which all possible precautions are taken to prevent the infection spreading from patient to patient, 1.81 per cent. of all the cases of typhoid fever have been of hospital origin, the advisability of isolation of typhoid-fever patients is certainly worth considering. As in this climate, most of the cases occur during the summer and fall months, when artificial heat is not necessary, there could be cheap temporary wards erected, or even tents, which could be taken down during the winter months, and the few typhoid-fever patients then admitted could be treated in the smaller rooms of the permanent hospital. The danger to the nurses and doctors would also be much less, as having exclusive care of typhoid-fever patients, the personal disinfection and prophylactic measures could be carried out much more effectively.

AUTOPSIES ON TYPHOID-FEVER PATIENTS.

It would seem unnecessary and somewhat presumptuous to call the attention of pathologists to the part they play in the spread of the typhoid infection. Yet in hardly a pathologic laboratory are any precautions observed. The autopsies are performed in the ordinary manner; the organs, even the intestines, are washed in running water, which is allowed to pass into the sewer unsterilized. Students are permitted to handle the infected material without subsequent sterilization of the hands.

From what precedes, it is evident that this is not as it should be. The remedy is self-evident, the details of which are comparatively simple.

The object of this paper is not so much to formulate a complete set of rules for the guidance of physicians in carrying out the methods of prophylaxis as to urge on them the necessity of these measures, the details of which are comparatively simple when the principle is thoroughly recognized. This method of stamping out typhoid fever is not based alone on theoretical grounds, but there is ample actual proof for the statement previously made that in this way typhoid fever may be eradicated from this country. An interesting graphic chart in the report of the secretary of the state board of health of Michigan for the year ending June 30, 1901, shows the effect of isolation and disinfection in a state where it is impossible at present to carry these measures out completely. Where isolation and disinfection were neglected, there occurred on an average 6.72 cases in each outbreak, with an average mortality of one. Where isolation and disinfection were observed, there averaged only 2.22 cases in each outbreak, with an average mortality of 0.39. But where these measures have been carried out completely, even the entire suppression of typhoid fever in a given district has been attained. During the past year, Professor Koch, who is the leader of the movement now being vigorously carried on to stamp out typhoid fever in Germany by means of isolation and disinfection, gave a most brilliant demonstration of the success which may attend such efforts. With a corps of assistants he fitted up a laboratory in Trier, a locality where typhoid had got a firm hold. By bacteriologic methods, he was able to demonstrate 72 persons to be suffering from typhoid infection. As soon as the nature of a case was established, isolation and vigorous disinfection was practiced. The result was that within three months no more typhoid bacilli were discoverable, the patients were cured, no fresh cases arose, and so far as that group of villages was concerned, typhoid was exterminated. Since, in other groups of villages situated under strictly comparable conditions, but where these methods of dealing with the disease were not practiced, typhoid continues to be prevalent, it may reasonably be inferred that the disappearance at Trier was not spontaneous, but due to the methods of identification and disinfection which were used.[5]

In Germany, where public measures may be much more under the direct control of the government than here, the problem is undoubtedly a simpler one than with us. Possibly here the ultimate end must be a similar control by the government, but this will come slowly, and in the meantime the physicians should make a determined stand. and the result may be reached before the slow-working processes of law can be put in motion.

In brief, let us make every effort to make an early, positive diagnosis. If unable to do this, we should not wait for a positive diagnosis, but when we suspect typhoid put measures for prophylaxis in operation at once. Let us not neglect our case because others are being neglected, recognizing that each case is an added danger. Let every physician remove as much of the danger as he can, then there will be fewer cases for the others to neglect.

THE ABUSE OF DRUGS.*

JOHN V. SHOEMAKER, M.D. LL.D.

Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine in the Medico-Chirurgical College.

PHILADELPHIA.

All drugs which are potent for good contain the possibilities of evil. This statement applies with equal truth to most, if not all, of those natural agencies which we employ—not as generally as we should, perhaps—in our struggle with disease. A superabundance of food, indigestible or illy prepared viands, create digestive disorders which are liable to eventuate in chronic and incurable lesions. Excessive exercise in the form of athletics may lay the foundation of organic heart disease. We must study minutely the proper methods of applying electricity if we would derive the benefits inherent in that powerful agent. In the same manner might be pointed out the reverse side of the influence of every drug or agency employed in medicine.

Nothing is more distinctive of modern methods of teaching therapeutics than the preliminary attention given to the physiologic action of drugs. We seek to understand the action of medicaments on normal organisms with a view to deducing and explaining their action in disease. Let us not, as physicians, forget for an instant, therefore, to recognize their untoward effects. Theoretically, indeed, we will usually acknowledge the defects of our instruments of warfare but in the exactions of daily practice we are apt to lose sight of the fact. Medicinal substances are often used too freely, too long, or in too strong doses in cases which could be more speedily, decidedly, and permanently relieved by the natural agencies which we possess but of which we make too little use. It is natural and easy to fall into a routine [illegible] but it is our duty, as reasoning and [illegible] to strive against this tendency. We must study when to withhold, as well as when to give, drugs.

People at large—our patients—very generally expect more of drugs than is within the power of those substances. They look for specific effects. To their conceptions the name of a disease should suggest a remedy. They are necessarily ignorant of the fact that effects differ according to the dose given and the condition of the patient's tissues, organs and secretions. The aim of the therapeutist should be to handle his remedial agents, of all kinds and as far as possible, as instruments of precision. This object he will best achieve by studying not the name of the disease but the disease itself, in all its varying phases, not forgetting the personality of the patient. In the management of the sick let us attend, with at least equal care, to the nursing, the diet, ventilation, hygienic surroundings, exercise, where that is possible, passive exercise, where that is suitable, the therapeutic properties of water, massage, and electricity. These agencies, intelligently managed, can often accomplish more lasting good than drugs. I believe that we, as physicians, should rely more on natural agencies and less on medicinal substances than, perhaps, we have been in the habit of doing in order that we should not ourselves encourage an abuse of drugs and that we should be able to set a consistent example to the public on this subject.

For, as we all admit when our attention is directed to the matter, there is, on the part of the general public, a widespread habit of drug-taking, which is always injurious in the end, and often ruinous. Large numbers of people exhibit a strange fondness for taking medicine on their own responsibility. Many have favorite remedies, to which they have recourse when troubled by certain symptoms. In some instances a belief in these substances has been inherited. Some traditional knowledge of the properties of herbs is acquired by country people who, moreover, are not infrequently obliged to depend to a certain extent on their own resources, especially in the more sparsely settled districts. In the cities a great fountain head of the habit of self-prescribing is the advertising quack with his space in the daily sheets, his testimonials and his "little book." Again, the practice is well nigh universal of offering advice to friends. The man or woman who knows "what is good for" any symptom or collection of symptoms is always with us, like the poor. Thus a mass of imperfect information or false knc [illegible] treatment of disease is always in [illegible] from mouth to mouth.

Another prolific source of indiscriminate drug-taking is the prescribing druggist. I am sorry to say that this class includes many druggists throughout the land. In addition to the patent medicines which they carry in stock they seldom, if ever, hesitate to prescribe for any customer who comes to them complaining of any symptoms. I have the utmost respect for the scientific pharmacist and pharmaceutic chemistry. Pharmacists have aided the progress of medicine in various ways. They have isolated active principles; they have suggested improved preparations; they have, to a large extent, replaced the crude and nauseous doses of our forefathers by articles, fluid or solid, which are equally effective and far more palatable. They are not instructed, however, in diagnosis, prognosis or therapeutics. Therefore, they appear to have no adequate conception of the fact that the most trivial symptoms may spring from some insidious and serious disease.

I was once, many years ago, called in haste to see a woman who had been seized with uremic convulsions. A large quantity of albumin was present in the urine. The convulsions were succeeded by coma and the woman died. She was *in extremis* when I first saw her, and the condition offered little prospect of successful treatment. The woman was in humble circumstances, and, like many of her class, had borne up as long as possible and had not complained much of her distress. She had, however, been lately troubled by a cough which she, of course, attributed to a "cold" and had sent to a neighboring druggist. Without seeing the sick woman, knowing nothing of the nature of her ailment, hearing of a cough, he sent a cough mixture. If this woman had in time been placed on proper treatment there is no question but that her life would have been prolonged.

The druggists generally reason that the preparations they send in response to such calls are harmless, at least, but this is not the sole, or chief, point. There are many cases where a preparation, harmless in itself, satisfies the patient for awhile and causes a delay in obtaining competent advice, which may entail injurious or even fatal consequences. Pharmacists should not assume responsibilities for which their education has not fitted them and which may place them in a very uncomfortable position.

Furthermore, nearly every pharmacist has a class of preparations of "his own make". These are always ready at hand to sell to whomsoever will buy. Ready-made preparations of every kind are offered for the chief ailments of humanity. Indigestion, kidney disease, rheumatism, insomnia, headache and catarrh are among the affections which are most exploited.

---

* Lecture delivered before the Hartford Medical Society.

One of the most common forms of drug abuse is the constant reliance on purgatives. The saline cathartics are so well known and so easily procured that every man considers himself capable of prescribing for his constipation. The waters of various saline springs are bottled and put on the market for public sale. Many people form a habit of relying on these salts instead of regulating their habits as regards exercise and diet and overcoming the sluggish condition of the bowel by natural means. The dependence upon cathartics adds to the difficulty it was intended to overcome. The muscular fibers of the intestine become weakened and relaxed. Disease of the mucus membrane may be established or aggravated as a result of the continual irritation. It must be remembered also that the alkaline bases are capable of exerting a depressing influence on the action and force of the heart. Their continued use is productive of anemia.

Another very popular and much abused class of preparations comprises those sold under the generic titles of bitters or stomachics. These are, to all intents and purposes, alcoholic drinks. Different preparations exhibit different degrees of strength, but many are equal to strong wines or whiskey. The whiskey which they contain is flavored with some aromatics or tonics and they are recommended as sovereign remedies for indigestion. The man—or woman—who announces himself as a total abstainer thinks that he is justified in using these bitters in order to stimulate appetite and digestive power. The mixtures are purposely made palatable. The presence of some vegetable matter does not detract from the flavor of the alcoholic beverage entering into their composition. It follows that their effect is principally that of alcohol itself, a primary stimulation succeeded by depression, a false sense of improvement followed by aggravation, a necessity of increasing the frequency and the amount of the dose. The advocate of temperance may become as devoted to his bitters as the ordinary drinker to his whiskey. Indeed, the mixtures of which I speak very often inspire a taste for drink which can only be satisfied in the usual way across the bar. I have no doubt that in very many instances the alcohol habit has grown out directly from the constant tippling of so-called bitters. An analogous custom is that of drinking preparations containing ginger. Either because the ordinary alcoholic beverages are not procurable or because a taste has been acquired for the fiery quality of the ginger, there are those who take their tipple in this form. In addition to the ill effects which a constant recourse to so strong an irritant as ginger must produce upon the mucous membrane it exposes its consumers to the danger of losing their sight; several cases of the kind have been reported originating in this habit.

The malt preparations are likewise often abused. This line of products is manufactured very extensively and largely used. They contain a percentage of alcohol which renders them a species of beer and some of them are, in fact, considerably stronger than the beers ordinarily sold in the usual way of the liquor trade. Some of the breweries now make malt preparations "for the use of the medical profession." They are recommended for their nutritious and gently stimulant properties, are extensively sold and their effect is almost, if not quite, identical with that of beer. Those persons who habitually, and on their own responsibility, consume preparations of malt might just as well go frankly to the beer saloon and drink in public. It is generally believed that of the two evils drinking in companionship is less injurious than "secret drinking," as it has been termed.

Two great evils of life are pain and sleeplessness. Headache is one of the commonest forms of pain, and for its relief there has grown up of late years, and especially since the coal tar products have been introduced, a class of preparations known popularly as headache powders or tablets. To a man almost, if not quite, the pharmacist puts up his own headache cure. In addition to these products there are many advertised in the street cars and sold by druggists and department stores. They are advertised as "instantaneous relief," "cures while you take," and other similar phrases. Not infrequently samples are thrown in at the door. These powders are principally composed of coal tar products, and the power which they possess of alleviating headache and other forms of pain makes them exceedingly dangerous unless prescribed in proper doses and used under the supervision of a physician. These agents are capable of depressing both the sensory and the motor nerve tracts. Excessive doses, or ordinary doses in susceptible individuals, may have a weakening action upon the heart, reduce the temperature of the body and injuriously affect the composition of the blood. I am personally cognizant of a number of cases in which very serious symptoms resulted from taking headache powders.

These evil consequences are particularly rife among anemic and neurotic persons, especially women. One such individual of whom I have knowledge had bought headache powders and taken them for the relief of distressing headache until, upon one occasion, she was seriously attacked. The pain in the head was assuaged, indeed, but in its stead she was prostrated to the verge of syncope, was nauseated, sweated profusely, her face became cyanotic, the action of the heart and pulse exceedingly feeble. That young woman had a lesson which will perhaps last her the remainder of her life. These are some of the typical manifestations which are produced by the class of substances which enter into the composition of these headache powders or tablets. Other signs of toxic influence which may occur are: Salivation, discharge from the nose and eyes, vertigo and depression of the temperature to a subnormal degree. Convulsions and vomiting of blood have also been witnessed.

Furthermore, the people who acquire the habit of lulling pain with headache powders are exposed to danger in another direction. They may limit themselves at first to a single powder, but the invariable tendency is to increase the dose and shorten the intervals. This was, in fact, the case with the young woman of whom I have made casual mention. She imagined she could take augmented doses with impunity. We observe the same feature appearing in reports which are given of intoxication by coal tar derivatives. Of a man we read that "he took a dram and a half within four hours." A woman "took one dram in two portions within a short time of each other."

Many such instances can be collected from the literature. A great many cases, no doubt, occur which never find their way into print. From time to time fatalities from this cause have been reported in medical journals and in the daily newspapers. We have all read of such instances.

Dr. J. Ashburton Cutter[1] published an account of a case of poisoning from migraine tablets, which was made the basis of a suit for damages. On the recommendation of a drug clerk a healthy young man had taken two tablets of "Quick Headache Cure" and two hours later a third. Very soon after the third dose the man became unconscious, perspired profusely, the heart was feeble and irregular, respirations shallow, lips blue, and the face presented a death-like aspect. The patient was revived from the attack but his nervous system suffered a shock from which, eighteen months later, it had not recovered. It was shown by analysis that each tablet contained 3 grains of acetanilid, 2 grains of monobromated camphor and 1 grain of citrated caffein. As acetanilid is slowly soluble it was supposed that the patient received the effect of the entire 9 grains, dissolved at about the same time by some hot coffee which he drank.

The United States Dispensatory notes one case of death from 5 grains of acetanilid. A powder of similar composition, in which salicylic acid was substituted for the acetanilid was once naively described to me by its maker, who appeared to have no idea that salicylic acid was capable of producing any ill consequences. Similar objections are to be made to the "rheumatism cures" which are so abundant in the stores. Many of these contain sodium salicylate, others potassium iodid. Neither of these substances can be taken indiscriminately or for a considerable period without mischief. Salicylic acid may depress the heart and injure the nervous system. It is much more effective in acute than in chronic rheumatism and is an agent which should never be taken upon the advice of irresponsible persons. The phenomena of iodism are familiar to us all and are not infrequently excited by comparatively few doses. The continual use of alkalies weakens the heart and impoverishes the blood.

All the analgesic remedies, anodynes and hypnotics, are susceptible of abuse, and it is by this class that the worst human wrecks—physical, mental and moral—are produced. Opium and cocain are the favorite drugs of habitués in this country. Chloral is abused by not a few individuals. Cannabis indica has its victims but is less extensively used in this country than in the East.

Opium, one of our oldest and best remedies, when used with circumspection, is also the one which from ancient times has been extensively used, or rather misused, by large numbers and for the purpose of producing pleasurable intoxication. The train of symptoms which the habitual consumption of opium or morphin induces, the gradual enslavement of the will and deterioration of morals which it causes, are so well known that I need not rehearse them, especially in this place and this company. Opium addiction has been studied from every point of view. Like other great problems which the medical profession must face the habit has an important sociologic side. The unrestricted sale and use of cough mixtures containing preparations of opium is to be deprecated, as it may lead to the formation of a habit. All kinds of cough mixtures are indirectly injurious when taken without medical advice. Nauseating syrups disturb and lessen the digestive capacity. It is pitiful to think how much harm they may accomplish when taken without advice or supervision in the first stage of pulmonary tuberculosis.

The great source of opium addiction, however, must be an experience of its effects in relieving pain. In addition to this cause, in our large cities, and especially where Chinese congregate, many acquire the habit from going out of curiosity to some den and smoking the opium pipe. There is a certain class of young people who are weak enough to look on such experiences as an evidence of their knowledge of the world. These are precisely the individuals who fall victims. They go to opium dens exactly as they first go to the liquor saloons.

Cocain is a recent addition to our list of intoxicants. Already, however, it has established a wide sway. As with morphin, the hypodermic syringe has provided a way of acquiring speedily the effects of the drug. It is not exactly germane to my subject, but I would simply note that in my judgment the hypodermic injection for the relief of pain may be abused and may suggest to the patient the capabilities of intoxication by morphin or cocain. The effects of cocainism are deplorable. The people who are enslaved by these unfortunate habits are for the most part neurotic and in a certain proportion they inherit a predisposition to insanity or the readiness with which they fall a prey to a pernicious habit is in itself a precursor of mental alienation. A peculiar complication of some of the cases of cocainism is that its victims had formerly been addicted to opium, and, indeed, may combine the use of the two narcotics. Nay, alcoholism also may be included in the lamentable pathologic combination.

Sleeplessness is truly a great ill. In addition to the deprivation of natural rest, which is a debilitating factor, it is a source of actual distress. The active mind creates a sort of torture for the sleepless. It is no wonder, therefore, that the victim of insomnia should prize the power of chloral. It is characteristic of these patients that they have a species of superstitious dread that they cannot sleep, and this feeling in itself increases the difficulty. Consequently, one who has derived a refreshing slumber from a dose of chloral is very likely to take another dose the next night, and in this manner lay the foundation of a habit which will cause more injury than the insomnia. If 10 grains lose their effect the quantity will be raised to 15, and if one dose will not cause sleep it will be repeated. Chloral is not a substance which can thus be used with impunity. It weakens the functional activity of the brain and spinal cord, it enfeebles the heart both by an influence upon its muscular tissue and the cardiac ganglia, reduces arterial pressure and has a deleterious effect upon the composition of the blood. The constant use of chloral engenders muscular debility, may occasion epileptiform convulsions, and even a condition akin to that of delirium tremens. Sudden death may take place from failure of the respiration or circulation.

The abuse of drugs may legitimately include a consideration of alcoholism. This is another of those broad themes which is of interest and importance from many other points of view than the medical. The name of Dr. T. D. Crothers is identified with the scientific study of chronic inebriety. The excessive use of alcoholic liquors is not regarded with the social tolerance, or even approbation, that it was in the days of our ancestors. Still we have among us innumerable men who esteem it an admirable joke to entice their fellows to gross drunkenness. Social drinking habits are all too prevalent. We, as physicians, are often brought in contact with all phases of alcoholic intoxication. The physical and mental outcome of drink are particularly evident in such an institution as Walnut Lodge Hospital. We all meet constantly with the grave structural mischief which chronic alcoholism has wrought. Perhaps each of us has numbered among his acquaintance or clientele some of those unfortunate individuals who are victims of imperative impulse, known popularly as periodical spreers. According to my observation, most such persons have been of decided and resolute character. During their intervals of sobriety they are usually men of influence and industry.

---

[1] Medical Bulletin, March, 1903.

The advocates of total abstinence, and especially of prohibition, have often injured their cause by the extravagant claims and assertions which they have advanced. Scientific temperance, if I may use such an expression, is now the most promising factor in the suppression of alcoholism. In Europe, where drinking habits have been far more universal than in the United States, the medical profession has been forward in instructing the populace as regards the destructive influence of alcohol. France, formerly regarded as a temperate country, seems to have become demoralized and has taken to strong spirituous beverages instead of light wines and *eau sucrée* (sugared water). Germany is awakening to the doubt whether unlimited beer is an unlimited blessing.

There is one duty which members of the medical profession should realize, not only as regards alcohol but also respecting those drugs which are capable of forming habits, such as opium, chloral, cocain and others which I have enumerated. We should be wary in our recommendations and prescriptions. We should discountenance counter-prescribing and self-prescribing. It is my custom in ordering alcohol to indicate the exact liquor, dose and time of taking the article. In this manner it is my intention to preclude, as far as possible, the danger of abuse. When I prescribe alcohol it is as a medicine and not as a beverage. I deprecate the loose way in which I have been told that some physicians permit themselves to recommend drink. One man related as an instance of this practice that, consulting a physician for a "cold", he was advised to go out and "get a load on", and, he added, "it brought me around all right". I have been told of others who advise patients to take, for instance, six or eight glasses of whiskey. The amount of a drink of whiskey is a very variable quantity. We cannot realize our responsibilities too keenly in these matters.

It is not within our power to prevent individuals from dosing themselves with all kinds of drugs and nostrums, but we can, at least, in prescribing for the sick, endeavor to have a reason, based upon its physiologic action, for every article which we employ. We can watch the effects of our remedies and discontinue them when signs of danger or abuse are exhibited. We can be careful in ordering narcotics and especially in injecting them beneath the skin. In my own practice I rely much on hygiene, diet, massage and electricity. With the aid of such powerful agencies we can minimize our use of drugs.

I would not be understood as uttering a word against the intelligent use of drugs, based on a knowledge of their physiologic action and their indications in given cases. We must remember, however, that temperance is a word not restricted to the subject of alcoholic drinks. We should be temperate in eating as well, and it behooves physicians to be discreet in the employment of drugs.

PROSTATECTOMY.

REPORT OF 51 CASES OPERATED ON FROM MAY 6, 1901, TO FEBRUARY 26, 1904.

JOHN B. MURPHY, A.M., M.D.
CHICAGO.

The surgery of the prostate is rapidly approaching that of the appendix and gall bladder in its significance to the surgeon and patient. Until very recently the prostate was not treated in the masterful and efficient manner in which other organs, as the uterus, tubes and stomach were handled surgically.

In considering this subject to-day I trust I will be permitted to omit the details of anatomic relations and physiologic functions of the prostate, described in full in my recent article on the subject. I will, however, go more into the details of the clinical aspects of the cases. The etiologic factors, the pathologic conditions of the bladder and kidneys at the time of the operation, and the patient's general condition will be more carefully treated.

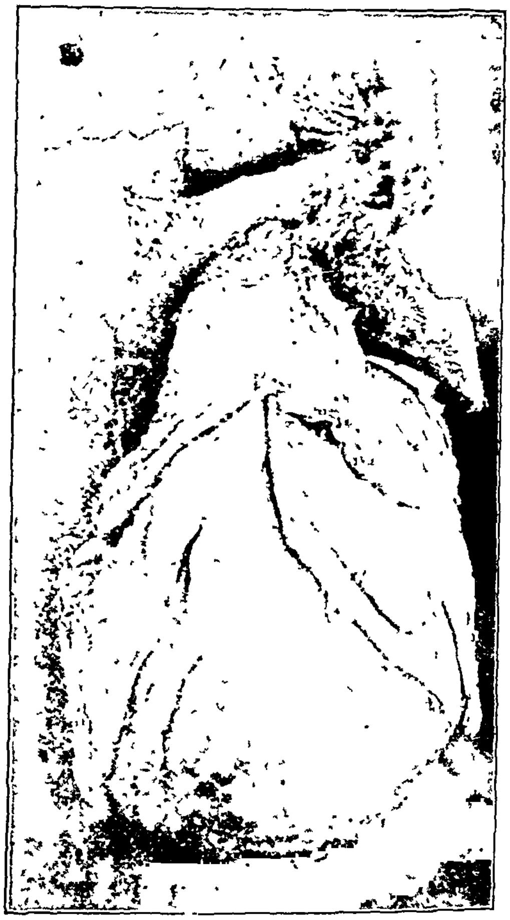

Fig. 1.—Shows relation of the prostate to the deep perineal fascia, the bladder, the seminal vesicles and ureters. (Photographed from dissection by Prof. W. T. Eckley.)

Experience has produced a number of changes in the technic of the operation and as time advances we are able to procure more speedy and complete recoveries than in our earlier cases. It is very gratifying to be able to report 51 consecutive cases of prostatectomy with but a single death due directly to the operation. In this one case the operation of prostatectomy would not have been undertaken had it not been for the urgent symptoms produced by the large stone in the bladder. The ultimate results have been far more gratifying than I expected, as will be shown by a perusal of the individual histories with the later reports of the patients.

Since I called attention to the enlargement of the lumen of the prostatic urethra that sometimes occurs with hypertrophy of the gland and advised the removal of a portion of the floor with a median suture of the lateral walls to form a new floor, the recoveries have been more rapid, and there has been no case of extravesical accumulation of urine during micturition with subsequent dribbling. The extra vesical pouch, or dilated prostatic urethra, can be readily recognized by the surgeon who carefully examines the prostatic urethra at the completion of the operation. It can also be demonstrated on the cadaver when prostatic hypertrophy is present. If this pouch is not recognized by the operator and properly treated, the operation of perineal prostatectomy will occasionally fail to produce that primary and complete relief which we desire to secure for the patient.

It appears to me that suprapubic prostatectomy will in the future be reserved for the exceptional cases of enormous hypertrophy of the gland, or the cases of pedunculated middle lobe with stone, notwithstanding the brilliant results attained by my friends, Mr. Freyer of London and Mr. Moynihan of Leeds and by myself. That the Bottini operation will entirely disappear as a method of treatment seems to me certain, for it is unscientific, inaccurate and hazardous in its technic and unreliable in its permanent results It must, therefore, vanish as intrauterine electrolysis did.

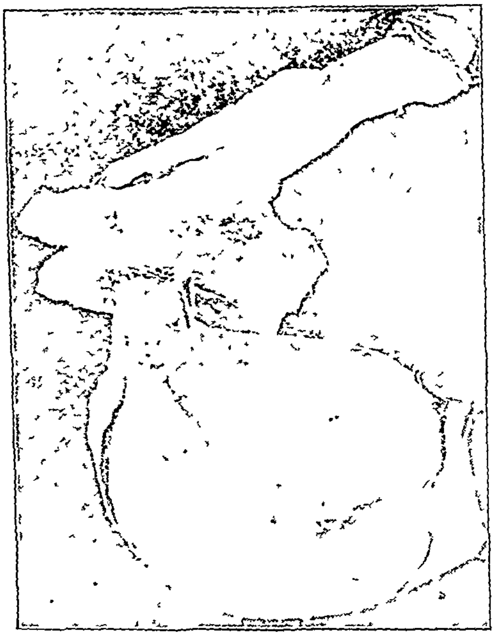

Fig 2.—Photographed from dissection by Prof W T Eckley Shows relation of prostate to deep perineal fascia, bladder and seminal vesicles lateral view

ANATOMY

The prostate may be regarded as situated in front of the bladder, entirely behind the triangular ligament or deep perineal fascia (Figs. 1 and 2), immediately anterior to and in close contact with the rectum and completely surrounding the prostatic urethra. It is tunneled by the prostatic urethra, which occupies the second anterior fifth of the gland, from before backward. Three-fifths of the normal prostate is behind the posterior level of the urethra (Figs. 3 and 4). Its firmest fixation is by its attachment to the posterior layer of the triangular ligament. When the ligament is divided, therefore, and the prostate liberated, it permits of considerable latitude of motion. On the anterior surface it is rather loosely attached to the urethra; on the posterior it is firmly fixed to it. The mucous lining of its glands and of the ejaculatory ducts and prostatic sinuses are continuations of the mucosa of the urethra (Fig. 3), so it is not possible to remove the entire prostate without removing the prostatic portion of the urethra behind at the veru montanum. It is possible to remove the lateral and posterior lobes of an hypertrophied prostate, allowing the isthmus to remain, and retain the anterior portion of the urethra and three-fourths of its circumference. The anterior wall of the urethra is crescent shaped, its convexity forward. The posterior surface of the urethra vaults forward into this crescent, the elevation being made up of the colliculus, utriculus, ductus ejaculatorii and the connective tissue surrounding them (Fig. 5), and the middle lobe, so-called, behind, as shown in Fig. 6. The middle lobe, in the normal anatomic condition, is a small, bullet-shaped, tongue-like projection from the base of the prostate, posterior to the urethra. It is not a lobe, as compared with the lateral lobes, but is merely a projection in the direction of the bladder from the posterior commissure, between the lateral lobes. When the lateral lobes and posterior commissure are removed, therefore, it is practically detached except from the mucosa.

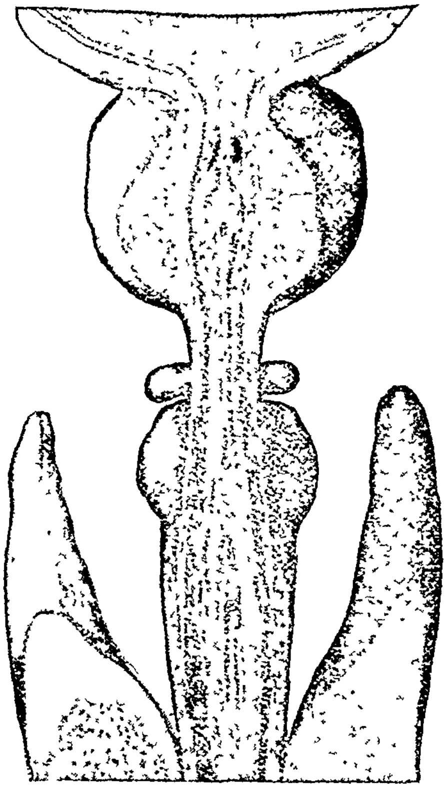

Fig 3.—This and Figure 4 show the relation of the prostate to the prostatic and membranous urethra, as well as the relations to the bladder wall and seminal vesicles (Toldt)

The gland is surrounded by a distinct capsule (Fig. 5), which is smooth over the lateral lobes but is depressed into the gland and divided into layers around the vessels in the median line. This vascular area running parallel to the urethra and directly in the central line has been preserved, during a prostatectomy, as in Young's operation. Capsular divisions, therefore, in the removal of the gland should be made over the lateral lobes and parallel with the urethra, that this vascular area may not be invaded until the lateral lobes are decapsulated and prepared for extirpation. Hemorrhage is thus avoided. The seminal vesicles recede from the prostate along the posterior wall of the bladder, and are closely attached to it. The vesicorectal fold of peritoneum is a long distance from the prostate and in subcapsular enucleation its integrity is not in danger of being disturbed.

The arterial supply of the prostate is from the inferior vesical and middle hemorrhoidal arteries. These subdivide at the inner surface of the capsule into small arterioles, and when the true capsule is peeled off they give rise to but little hemorrhage. The veins which form a plexus in the capsule empty into the vesicoprostatic plexus. In fleshy, phlegmatic patients there is a large plexus of veins in front and a little to the side of the median line. This bleeds profusely unless care is exercised to divide the capsule near to the middle line and displace it laterally without laceration. The lymphatic supply is meager and in the capsule practically nil, so there is no danger of absorption if one keeps within this space. The vessels accompany the venous plexus and finally end in the internal iliac nodes.

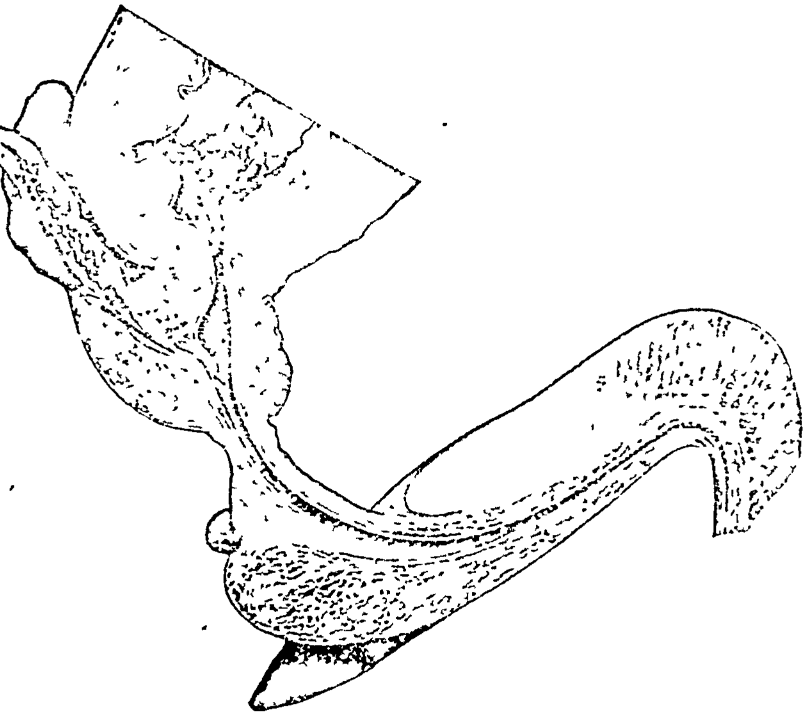

Fig. 4.—Shows the relation of the urethral mucosa to the ejaculatory ducts and prostatic sinuses, and the relation of the prostatic substance to the urethra. (Toldt.)

The nerves of the prostate are branches of the hypogastric plexus.

The glands are of the branched or tubular variety. They secrete a milky fluid which appears to play an important part in the motility of the spermatozoa, as without the addition of this fluid, in some of the lower animals, fecundation can not take place.

While in its normal anatomic position the prostate is located in front of the bladder and surrounds the urethra; in its hypertrophied condition it has an entirely different relation to the bladder. It normally extends backward onto the bladder only as far as the sphincter vesicæ internus (see Fig. 7, which shows the bladder wall with prostate removed). In its pathologic or hypertrophied condition it encapsules the neck of the bladder in a cuff-like manner, extending several inches upward on its wall, and often protrudes into the vesical cavity, carrying on its surface the mucosa vesicæ. This intravesical protrusion may be so complete as to form large sessile (or even pedunculated) masses springing from both sides and behind. They can be readily enucleated through the suprapubic incision. Occasionally a pedunculated lobe may be extruded through the muscularis and only retain the mucous covering. This, however, rarely occurs except from the posterior lobe. In its normal anatomic condition the muscular fibers of the prostate are continuous with the muscular fibers of the apex of the bladder wall, but as the prostate enlarges it extends upward as a cone-shaped body around the neck of the bladder, or bulges through its wall, and its muscular fibers in the upper part appear to be distinctly separated from those of the bladder. This anatomic relation gives distinct assistance and guidance as to the best method of removal or separation of the prostate from the bladder wall. At the extreme apex of the bladder it would be difficult to distinguish between the prostatic and vesical muscular fibers, but if the base of the prostate be first exposed the gland can be shelled from the bladder from above downward with comparative ease and safety to the integrity of the vesical wall. In other words, if we look upon the prostate as a cuff closely attached at its apex to the bladder and loosely attached at its base, we can see how its lateral lobes can be scrolled or rolled forward, with the assistance of hook retractors, until the apex attachment is reached. This may then be divided with scissors and the size of the prostatic urethra determined.

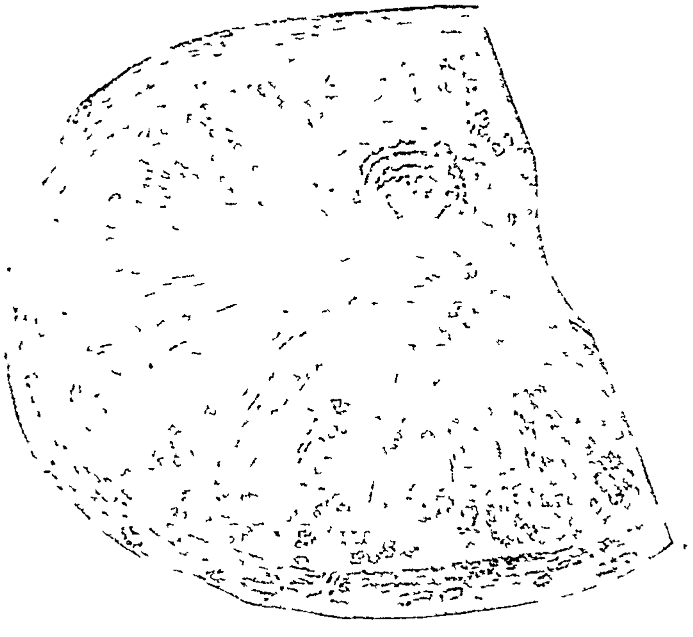

Fig. 5.—Shows the horseshoe shape of the prostatic urethra, also the elevation of the floor of the urethra into the crescentic anterior wall, which covers four-fifths of the entire circumference of the urethra. The fibers of the prostate extend into the verumontanum.

Not only is the sexual function diminished or lost by the removal of the prostate, but it is materially interfered with by prostatotomy, as in the Bottini operation. Guiteras says: "The patients are not always incapacitated for sexual life by the Bottini operation." From our observations it would appear that the prostate gland is placed over the neck of the bladder as a secondary muscular development, for its greatest bulk is made up of muscular tissue, and the glandular element is small in amount. The urinary control is entirely independent of the prostate, as was clearly demonstrated in my original article[1] and additionally supported by my subsequent experience. It is rather an accessory to the sexual function than to the urinary apparatus. Dr. G. Frank Lydston has criticised my statements on this subject

---

[1] The Journal A. M. A., March 22, 29, 1902.

He believes that prostatectomy does not produce sexual incompetence and that the patients who complain of it after the operation were probably impotent before, as most of them are old men whose sexual powers are in abeyance. From my experience, as shown in the late reports of the following cases, I cannot agree with him, although the power of erection is not completely lost in all of the cases.

ETIOLOGY.

The age at which prostatic enlargement begins is variously estimated. L. Bolton Bangs believes that it begins a considerable time before the fiftieth year, and that the earliest manifestations are not generally recognized.

Prostatic hypertrophy is extremely rare in Japan, India and China, while in Turkey it is of comparatively frequent occurrence. Schultze states that enlargement of the prostate is rarely found in the negro, although he describes one in which the middle lobe, obtained by autopsy, measured 5x7 cm., and microscopic examination showed a marked hyperplasia.

We do not believe that excessive sexual indulgence plays any more part in enlargement of the prostate than in the production of fibroma of the uterus, and it is well known that, proportionately, fibromata of the uterus are more common in the unmarried than in the married. Then again it is rare in such races and nationalities as the Japanese, Chinese, Negroes and Indians.

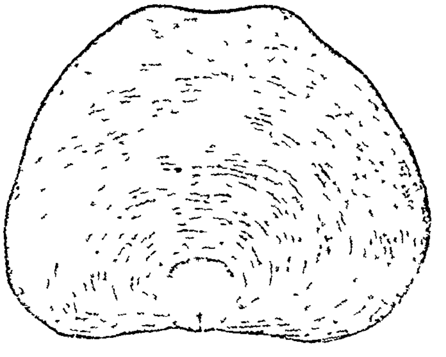

Fig 6 —Shows the teat like projection of the middle lobe into the floor of the urethra

Our exact knowledge of the etiology of enlargement of the prostate may be summed up by saying: "We know nothing definite about it."

PATHOLOGY.

Benign neoplasms and enlargements of the prostate resemble very closely, in their histology, mode of development and their relation to the organ itself, the nonmalignant neoplasms of the uterus. First, there are myomata, fibromata and combinations of these two—principally the combinations—and, second, not infrequently general hypertrophy of the entire gland without any distinct tumor formation, resembling closely the soft, flabby subinvoluted uterus. The enlargements are many times completely encapsulated, but in the great majority of cases they are closely connected with the prostatic tissue itself, as in the intramural fibroid there is always an enlargement and hypertrophy of the uterine tissue associated with it. In the lateral lobes the tumors are usually intramural, less frequently submucous. In the middle lobe they are often pedunculated, rarely intramural and practically never subcapsular. The degree of general hyperplasia is out of all proportion to the size of the small fibromyoma, which is encapsulated in the lobe. We believe, therefore, that the operator who is satisfied with an enucleation of these small tumors will not have good results ultimately, though primarily they may be gratifying.

Wishard draws particular attention to the mechanical part of the obstruction in hypertrophy of the prostate, and to the direction which the enlarged body takes, viz., toward the bladder, the urethra or the rectum, as the case may be. The size in one direction bears no particular relation to the size in the opposite direction. It interferes more or less with the urinary function depending on the direction of the pressure, whether it be on the bladder, urethra or rectum and the angle produced in the urethral canal. The small, teat-like middle lobe makes a trap door to the internal urethral orifice over the commissure formed between the enlarged lateral lobes, and is an important factor in the obstruction.

TREATMENT.

The medical treatment consists principally of the alleviation of symptoms of obstruction and their sequences, rather than any effort to reduce the size of the prostate. Rest, rectal enemata and suppositories, with hot fomentations, sitz baths, etc., gives the most relief.

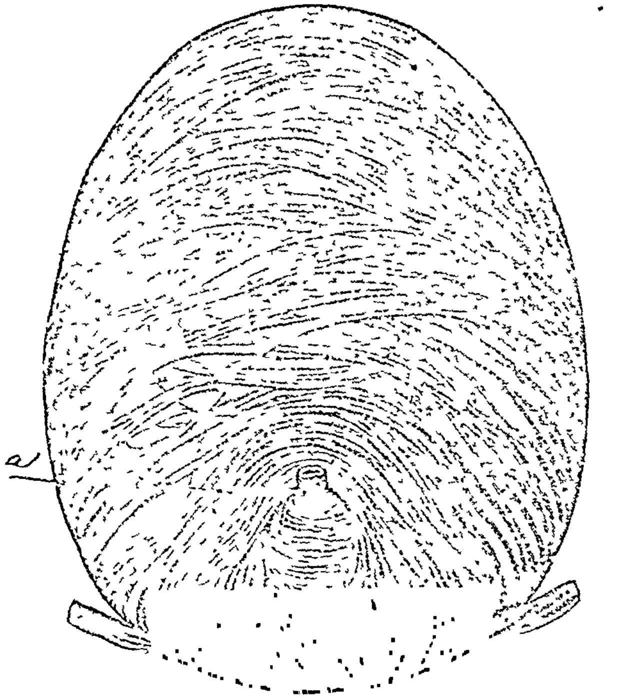

Fig 7 —Shows the muscle fibers of the bladder and the sphincter vesicæ internus (a) with prostate removed

The development of forceful and scientific procedures in the treatment of prostatic lesions has scarcely kept pace with operative procedures in other fields of surgery. It has, however, though tardily, developed on the same lines as its analogous organ in the female—the uterus—and the surgery of the prostate is now rapidly taking definite form on rational mechanic, anatomic and histologic bases. During the last quarter of a century the sufferer presented a lamentable picture: Usually a man of great energy, strong mentality and physically robust, indefatigable in his labors, and by these qualities had gained a competence whereby he could spend his declining days in comfort and the pursuit of pleasure were it not for his prostate. By this he was deprived of sleep, suffered intensely from pain, and saw no hope of relief except in death. This picture may not fit the few, but it does the many who suffer to a pathologic degree from prostatic enlargement.

Temporary catheterization is resorted to for the relief of urinary retention which comes on after some undue exposure, acute illness or traumatism. It should be done with all aseptic precautions and with *greatest* gentleness in mechanical manipulation. *It can always* be accomplished where there is absence of stricture of the urethra anterior to the prostate. There is no such condition as prostatic stricture. The urethra is always patent in its prostatic portion, and the obstruction offered to the passage of the catheter is caused by deformity of the canal, urethral pockets, prostatic sinuses and compression of the urethra by encroachments on its lumen from various directions by the enlargements or neoplasms in the prostate itself (Fig. 8). All of these occur on the posterior and lateral walls of the urethra; the anterior wall offers no obstruction. The ideal course of the catheter, therefore, is along the anterior wall of the urethra. It is only a question of proper manipulation and an estimate of the directions of the canal, for the successful performance of temporary catheterization. In this, force must play no part. It should and can always be accomplished by those of skill and experience, and the patient never forced to an immediate operation under these circumstances, when he is often in an unfavorable condition for operative procedure. The soft rubber catheter, with or without lead stilet, and the coudée catheter, preferably of large size, are the best instruments to use. In these primary retentions the bladder *may* be completely emptied without danger. Continued or chronic retention presents to the surgeon many distinctly different as well as dangerous phases. Here the bladder is often enormously enlarged, its veins are compressed, the walls anemic from pressure, the arteries frequently dilated, and advanced pelvic or peripheral renal changes may have taken place. Because of this protracted compression of the combined urinary surfaces, care must be exercised that this pressure is not too suddenly relieved, i. e., that the bladder is not completely emptied; otherwise, as we have found by experience, there is an immediate congestion of the urinary surfaces, and frequently shock, chills, fever and death. A chronic sufferer from vesical distention should never have his bladder completely emptied in a primary catheterization.

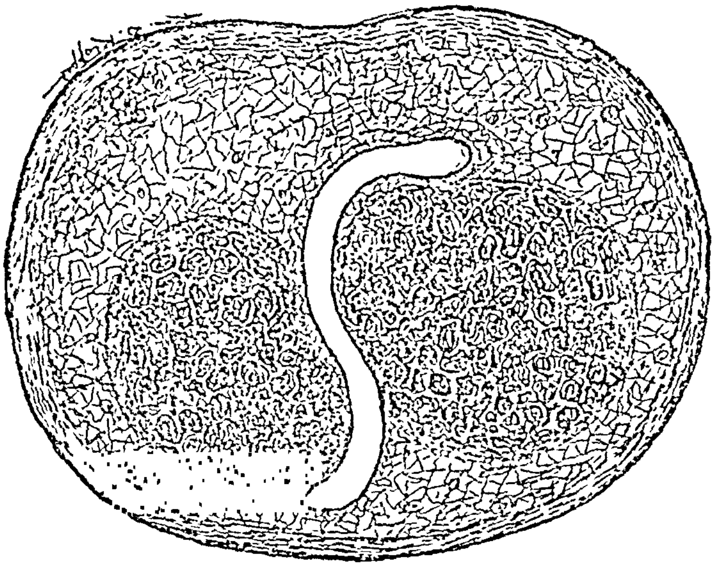

Fig. 8.—Shows changes in the shape of the urethra, produced by myomata (transverse section).

PROSTATECTOMY.

It is gratifying to note the advances that have been made by the medical profession in the operative treatment of prostatic enlargement in very recent times. Even so modern a man as Sir Henry Thompson said that he did not believe it was possible to operate on a case of enlarged prostate and have a result that would permit him to discontinue his catheter and still be able to empty the bladder and retain the urine. Now we know that these results are of daily occurrence.

The indications for prostatectomy are: (1) Prostatic enlargement to a pathologic degree, i. e., sufficient to prevent urination or cause large residual retention; (2) painful and frequent urinations; (3) as a cure for catheter life; (4) as a cure for secondary cystitis; (5) for the relief of pressure on the rectum; (6) painful and continuous priapisms of the aged, with perineal irritation and with or without emissions. It should be the operation of election where the patient is in condition to withstand operative procedure and the local and general conditions are favorable. The operation should not be considered nor used as a last resort. Local or spinal anesthesia should be preferred in selected cases, or better, epidural injections of 1 gram of a 1½ or 2 per cent. solution of cocain into the sacral canal through the hiatus sacralis, passing the needle up to the second sacral vertebra, that is 2½ inches in the bony canal above the notch.

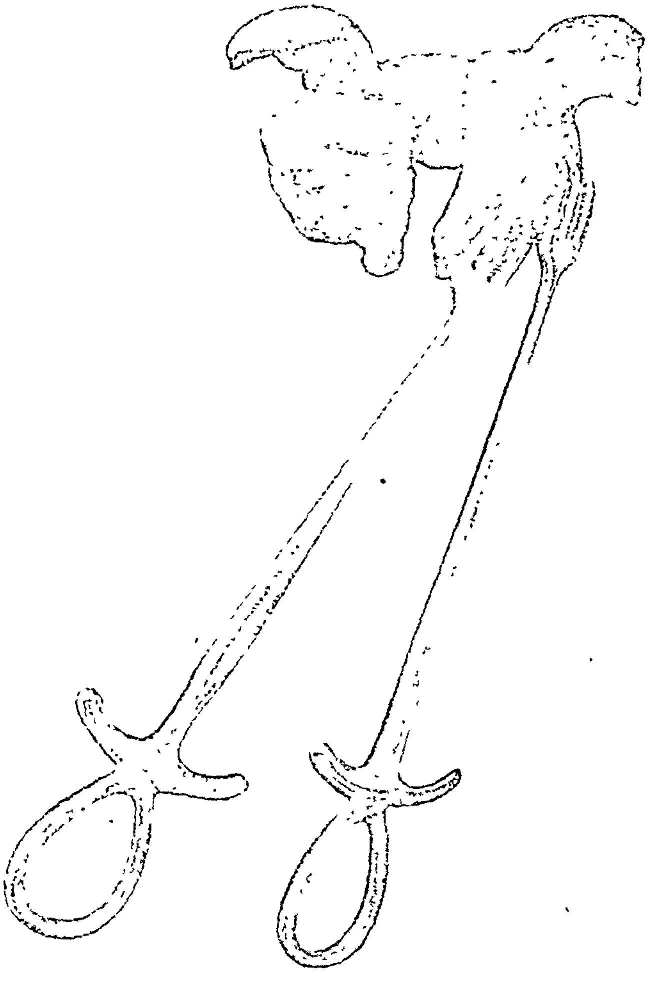

Fig. 9.—Showing hook retractors in place.

SUPRAPUBIC PROSTATECTOMY.

Dr. William T. Belfield of Chicago deserves the honor of being the first to follow a deliberate plan for the removal of the middle lobe through a suprapubic incision. This was not an accident, as suggested by G. Buckston Browne, but was a deliberately planned and executed operation, as was well known to many of the Chicago profession at the time. The honor is incontrovertibly his, while Dittle's operation was not deliberately planned and executed, but was done in an emergency. Mr. McGill and Mr. Atkinson of Leeds laid down more definite indications and lines of procedure three years after Belfield's original work, although we believe it can be said that McGill had no knowledge of the Chicago surgeon's technic at the time he performed his first operation.

The suprapubic route was the one uniformly followed in my ten years' service at the Alexian Brothers' Hospital. Either enucleation or cauterization was accomplished through a suprapubic opening, with the aid of curved scissors, Kocher dissector, volsella forceps and the index finger. The middle lobe was readily and easily enucleated, but the enucleation of the lateral lobes through the suprapubic opening was always a difficult, bloody, dark and unsatisfactory procedure, though many times gratifying in its relief to the patient. In the suprapubic operation there is practically no danger of opening the peritoneum, as the base of the prostate is situated fully half the length of the bladder below the most dependent portion of the vesico-rectal fold, and is very movable at that point. There is danger, however, of lacerating the rectum. To Mr. Freyer belongs the credit for the reinstatement and present advanced standing of suprapubic prostatectomy. The reports of his cases show very gratifying results. Moynihan of Leeds has had an equally gratifying experience with this method of removal. From a perusal of his article, however, it is clear that his drainage was not satisfactory, as he frequently resorted to irrigations of the bladder with 1 per cent. carbolic acid solution. The immediate urinary control and absence of urethral fistulæ are in favor of this operation, although the suprapubic leakage was annoying and lasted as long as fourteen weeks in one case. It persisted about seven weeks in the average case, but in one was closed on the fifteenth day.

Mayo Robson, years ago, 1887-1894, enucleated and excised large masses of the prostate suprapubically with very satisfactory results. The original operation, however, he desires, through a personal letter to me, to be credited to Mr. Leonard Atkinson, to whom he says is due the credit of the first enucleation of myomata of the prostate. Mayo Robson, in his able article, has left the stamp of his genius on this as well as on all other branches of surgery to which he had devoted his attention.

Dr. Ramon Guiteras collected 153 prostatectomies. Of these 110 recovered, 72.3 per cent.; 25 died, 16.4 per cent.; 17 were failures, 11.2 per cent.; and he concludes that the results in those that recover after prostatectomy are better than those following prostatotomy. He believes, however, that great care and judgment must be used in the selection of cases, and submits the general rule that "the large glands are favorable for enucleation and the small ones are best treated by prostatotomy. If the kidney be diseased, either medically or surgically, the Bottini should be resorted to."

(*To be continued.*)

Improved Technic of Agglutination Test of Typhoid.—E. Weil of Hueppe's Hygienic Institute at Prague announces (*Prager med. Wochenschrift*, May 12) that the most favorable temperature for the agglutination test is not 37 C. (99 F.) as hitherto assumed, but between 50 and 55 C. (122 and 131 F.) Agglutination occurs much more rapidly and more decidedly when the bacilli are thus warmed beforehand.

THE CULTIVATION OF THE SURRA TRYPANOSOME OF THE PHILIPPINES.

FREDERICK G. NOVY, Sc.D., M.D.,
Professor of Bacteriology, University of Michigan,
WARD J. McNEAL, A.B.,
Fellow of the Rockefeller Institute for Medical Research,
ANN ARBOR, MICH.
AND
CHARLES B. HARE,
Government Bacteriologist.
MANILA.
(From the Hygienic Laboratory, University of Michigan, Ann Arbor, Mich.)

Although the *Trypanosoma evansi*, the cause of surra, was discovered by Evans in India as early as 1880, and the disease itself has been studied exhaustively by Lingard (1893-1896), relatively but little attention has been given to the parasite itself. Koch, while in German East Africa in 1898, described the disease prevailing in that region as surra, because he was of the belief that surra and nagana or the tsetse-fly disease were identical. Bruce himself, in his work on the latter disease in 1894, inclined to the view of a possible identity of the trypanosome studied by him with that of Evans. Various other workers have held similar opinions, and even as late as last year Musgrave and Clegg[1] conclude that surra, nagana, mal de caderas, and probably dourine, are the same disease and that all are caused by *Tr. evansi*.

The immunity experiments of Laveran and Mesnil[2] and those of the late Professor Nocard, as reported by Vallée and Carré,[3] however, show conclusively that surra, nagana and mal de caderas are distinct entities notwithstanding the marked similarity in the symptoms of these diseases. Moreover, the difference in the morphologic characteristics of these organisms as shown in stained preparations, even when these are made from the same kind of animal, as for instance the white mouse, are such as to leave little doubt that they are distinct species.

A further and perhaps even more conclusive method of differentiation is to be sought for in the cultural characteristics of the trypanosomes found in these diseases. Thus, it has been shown that in artificial culture the *Tr. lewisi* is wholly unlike *Tr. brucei*. If, therefore, surra and nagana are one and the same disease, as has been asserted by some observers, it is evident that the cultures obtained from these sources must be identical in every respect. On the other hand, if such cultures show distinct differences, it can mean only one thing and that is that the organisms, and hence the diseases, are wholly unlike.

In order to approach this question it was necessary to secure living surra trypanosomes. These could not be obtained by direct shipment of the infected blood for, like those of nagana, they die out within a few days after the removal of the blood from the body. Accordingly, another procedure was resorted to. One of us (Mr. Hare), before leaving for the Philippine Islands last summer, was requested to inoculate blood agar tubes with surra blood and ship these to Ann Arbor. Inasmuch as this medium was the same as that employed for the cultivation of *Tr. lewisi*[4] and of *Tr. brucei*,[5] it was assumed that, out of a series of tubes thus sent, perhaps one or more would reach their destination with living and even multiplying trypanosomes.

[5] THE JOURNAL A. M. A., Nov. 21, 1903.

The first shipment was negative, but the second, consisting of three tubes, was even better than was anticipated. These tubes of blood agar were inoculated on January 1 with the blood of an American cow suffering with surra. The inoculated tubes were kept for three days in cold storage, after which they were shipped to Ann Arbor, where they arrived February 8, or 38 days later.[6]

One of the tubes was fairly rich in motile trypanosomes, the second was even better, while in the third they were very abundant. The appearance and size of the organisms were such as to leave no doubt but that they had developed *en route* and that the material received was in reality a culture of the Philippine trypanosome.[7]

It was evident at the outstart that the trypanosomes in this culture were entirely different from *Tr. lewisi* and *Tr. brucei.* Thus there was an entire absence of the groups or rosettes which are so characteristic of the cultures of these two organisms. The trypanosomes were all single and actively motile. They traveled as readily with the flagellum in the rear as with it in front. Another striking feature was the size of the cell, and especially the length of the flagellum. An even more marked characteristic was the presence and peculiar arrangement of granules within the cells and the distinct yellowish or greenish color of the granules and of the contents.

The contents of the cell in the case of the cultivated *Tr. lewisi* are colorless and almost homogeneous; at most, but a few very minute granules can be made out. On the other hand, *Tr. brucei* presents a striking contrast, since in cultures it shows one or two very large, bright and highly refracting globules in the otherwise homogeneous, colorless cell. The new trypanosome, however, showed large numbers of small granules or globules which varied from 0.3 to 0.5 μ in diameter. These globules, as well as the contents of the cell, possessed a decided yellowish or greenish color, an appearance quite unlike that of either of the other two trypanosomes. The globules were usually massed in the anterior third of the cell, that is, at the base of the flagellum, and only a few isolated granules were scattered through the remainder of the organism. (See Fig. 1.) In the divisional forms the granules were arranged in two parallel rows, as shown in Fig. 2, thus imparting a very characteristic appearance to the organism. Only exceptionally were individuals to be found which contained one or several large globules, 1 to 2 μ in diameter instead of the arrangement described. The latter may, perhaps, be looked on as dying or degenerating forms.

The trypanosomes thus received were apparently in perfect condition and had all the appearance of a healthy culture. As already stated, they were always single and were extremely motile, traversing the field of the microscope at great speed. When the flagellum was in front the side-to-side lashing was marked, whereas, when it was in the rear, the cell traveled with a rapid, straight, dart-like motion. The slender body terminated at one end in a delicate flagellum, which was usually as long and often even longer than the cell itself. Thus, the body of one large individual measured 21 μ while the flagellum was 28 μ in length.

The posterior end, especially when blunt, showed a rod-like tip or stylet, which varied from 2 to 4 or even 6 μ in length. (See Figs. 1 and 2.) The undulating membrane was not recognizable in the living organism.

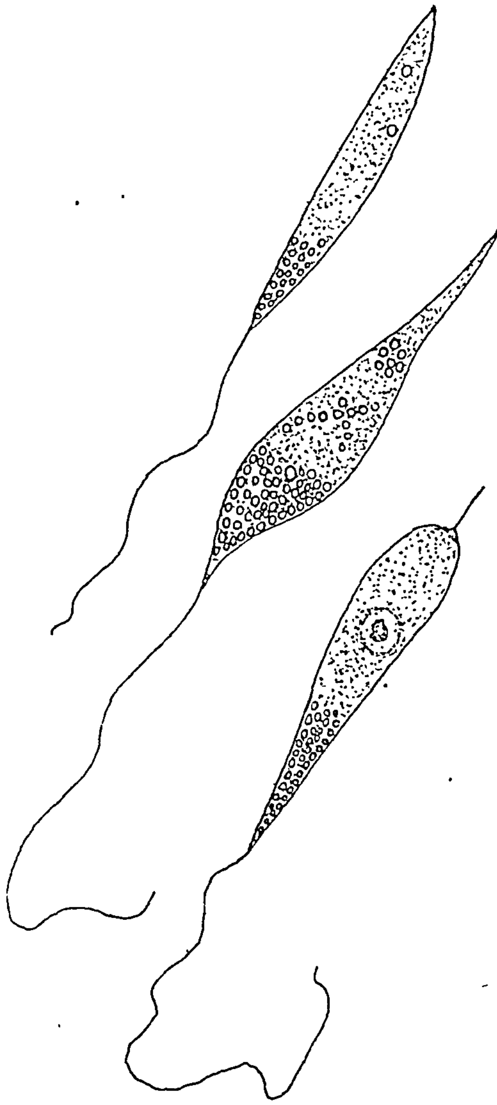

Fig. 1.—Philippine surra trypanosomes, from thirty-eight-day culture and drawn from a living preparation. Magnification, approximately 3,000 ×.

The total length of the trypanosomes, as might be expected in a culture, varied considerably. The exceptionally long forms measured from 40 to 50 μ. Most of the individuals ranged from 25 to 35 μ. The width of the cells varied from 1.5 to 2.5 μ.

As the cultures aged pear-shaped or spherical highly granular involution forms appeared. In the former type, measuring about 3 by 5 μ, the end was often provided with a flagellum 10 to 15 μ long, which still showed a slow lashing movement though the cell itself was motionless. The spherical forms varied from 4 to 9 μ in diameter, were very granular and often showed a remnant of the flagellum as a short, stiff, motionless whip. These involution forms, as in the case of *Tr. lewisi* and *Tr. brucei,* eventually gathered into large groups or masses, which at times filled the field of an oil immersion lens. Later on, perhaps as a result of autolysis, the round bodies broke up into masses of very minute granules.

---

[6] Since writing the above we received a third shipment of 3 tubes of inoculated blood-agar. The medium used was 3 to 2, 1 to 1 and 1 to 2. The tubes were 39 days en route and on their arrival showed no sign of trypanosomes.

[7] Since the publication of the work on the cultivation of *Tr. lewisi* Laveran and Mesnil have endeavored to apply the same method to the trypanosomes of surra and caderas. Under date of December 18 Dr. Mesnil wrote to one of us (Novy) that they had obtained with surra encouraging results quite analogous to those obtained by us with *Tr. brucei.* Just how far they were successful in their experiments we are unable to state, since they have published nothing on the subject. It may be stated in this connection that the culture of *Tr. lewisi* begun on May 16, 1902, and grown at room temperature, is now in its twenty-sixth generation. The other strain which we reported on, begun Dec. 4, 1902, and grown at 34 to 37 C., is at present in its sixty-seventh generation. The culture A of *Tr. brucei,* which was started Aug. 27, 1903, is now in its twenty-seventh generation.

The tube which contained the fewest organisms was the first to lose them. No living forms were found in it on the forty-eighth day. It is noteworthy, however, that in the richest tube the trypanosomes were still alive, though very few, on the sixty-fifth day. Under an ordinary cover-glass on a slide the organisms remained alive for many hours. In one instance where complete desiccation was prevented, by the formation of a dried ring, a few were still alive after fifty-two hours.

Immediately on receipt of the culture tubes several attempts were made to inoculate animals and to obtain a second generation. It was particularly desirable to secure an infection of animals, for in that event a constant supply of surra material could be maintained and this would serve as a point of departure for further cultivation experiments in case the original material failed to yield subcultures. It may be said in advance that all these attempts at inoculating animals and obtaining subcultures proved fruitless. Only a brief mention need be given, therefore, of these experiments.

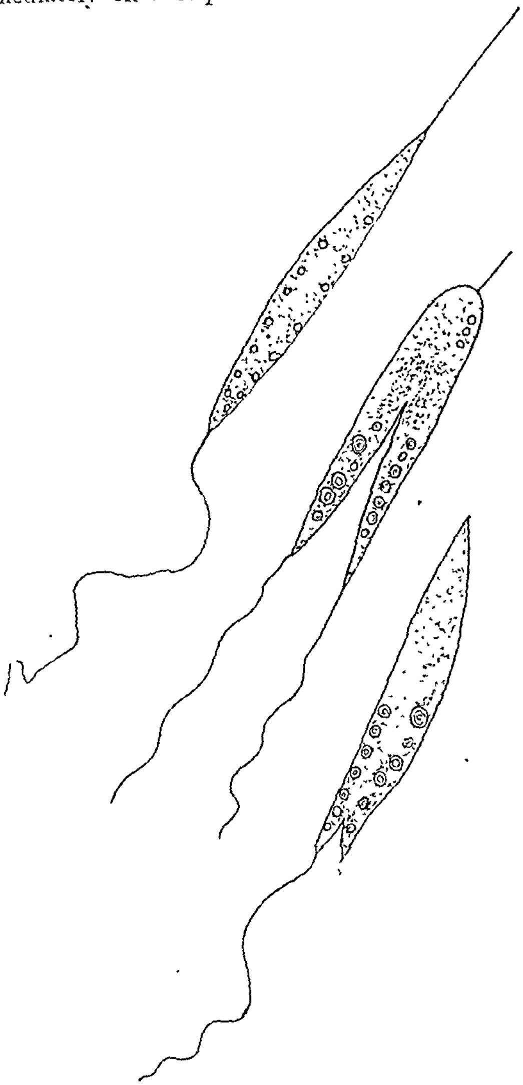

Fig. 2. From same preparation as Fig. 1.

A portion of the fluid from the thirty-eight-day culture, richest in trypanosomes, was injected into the peritoneal cavity of two white mice, two white rats and a guinea-pig. The mice and rats each received two drops, while the guinea-pig received a quarter of a cubic centimeter of the liquid. The blood of these animals was examined every day or two for a month for the presence of trypanosomes, but none could be found. The mice and rats remained alive and in perfect condition. The guinea-pig died on the thirtieth day, but at no time did it show any parasites in its blood. The heart blood drawn immediately after death gave a culture of a very minute bacillus. In order to detect, if possible, any trypanosomes that might be present, portions of this blood were injected into each of two white rats and two guinea-pigs. Both rats died on the sixth day and one of the guinea-pigs died on the seventh day. Notwithstanding daily examinations trypanosomes could not be detected in the blood of these animals. The heart blood of these animals gave a culture of the small bacillus mentioned. The second guinea-pig remained alive and in good condition for nearly two months. It was evident from these inoculations that the first guinea-pig did not die of trypanosomiasis, but of an infection following on the repeated examinations of its blood.

On February 18, when it was evident that the above animals would probably fail to develop a trypanosome infection, possibly because the dose employed was too small, the entire contents of one of the tubes was inserted under the skin of a guinea-pig. This inoculation likewise failed to infect.

The failure to produce infection in animals by the inoculation of the thirty-eight and forty-eight day culture of this trypanosome corresponds to the observations which have been made on *Tr. brucei.*[8] In the latter case first generations, 29 and 38 days old respectively, failed to infect mice. It would seem as if the unfavorable conditions under which the first generation is developing results in an early and complete loss of virulence. Since, in the second and subsequent generations of *Tr. brucei* this virulence is largely restored, it was hoped that a like result would be met with in the subcultures of this trypanosome. This hope, however, was not realized, for notwithstanding numerous and varied attempts to secure such subcultures, all efforts failed.

Between February 8 and March 1 seven attempts were made to secure a second generation. In all 38 flasks and tubes of blood-agar were inoculated. The blood-agar mixture varied from 1:1 to 2:1; the proportion of beef and water from which the meat extract was prepared for the nutrient agar varied from 1:1 to 1:8; and again the amount of sodium carbonate used in the preparation of the agar varied from nothing to 20 c.c. of the normal solution per liter. The nutrient agar contained as a rule 2 per cent. of agar and a like amount of peptone together with a half per cent. of salt. The inoculated flasks were kept at 5, 15, 25 and 34 degrees, but without avail. At no time was there any indication of a second generation.

It will be seen from the foregoing that the first generation, in artificial culture, of the trypanosome of the Philippine surra, was incapable of developing either in the animal body or in the culture media. The failure to obtain a second generation in this case must be ascribed to the fact that the culture was 38 days old when received and that the trypanosomes notwithstanding their apparently excellent condition were too enfeebled to reproduce. An exactly similar behavior, it should be noted, has been observed in connection with *Tr. brucei*, where the first generation, 29 days old, failed to infect animals or to yield subcultures on blood-agar media. It is possible, however, to obtain cultures from a first generation of the nagana trypanosome at a much later date than that just given, provided the amount of salts and other extractives in the medium employed are decreased. Under such special conditions it was possible to obtain a subculture from a first generation of *Tr. brucei* when 52 days old. Without doubt, under like conditions, a similar result can be obtained with the Philippine and other trypanosomes. Obviously no difficulty should be experienced in securing transplants from a first generation if such attempts are made on about the third to the fourth week.

---

[8] Journal of Infect. Diseases, vol. 1, p. 21, 1904.

The foregoing observations, although they are by no means as complete as we would like them to be, are nevertheless quite sufficient to show that the trypanosome of the Philippine surra is distinct from that of the South African nagana. It seems to us that there can not be any question on this point.

The studies of the past ten years have shown that there are not less than six very important trypanosomatic diseases in Africa. These diseases are (excluding those of rats, birds, amphibians and fish): nagana, dourine, galziektè, zousfana, Gambian horse disease and human trypanosomiasis. The latter designation includes the Gambian or trypanosomatic fever of Dutton and Forde and the so-called sleeping-sickness, which really are but different stages of infection due to *Tr. gambiense*, a fact which has been established by Bruce, Manson and Laveran.

In Asia, on the other hand, ever since the work of Evans in 1880, only one trypanosomatic disease has been recognized, namely, surra. This fact serves to indicate the need of a careful comparative study of this disease as met with in different parts of Asia and in the adjacent islands. It is more than probable that the term surra will be found to cover several distinct infections. On this point we have one observation to offer which is very suggestive and which obviously will require further study to insure its correctness.

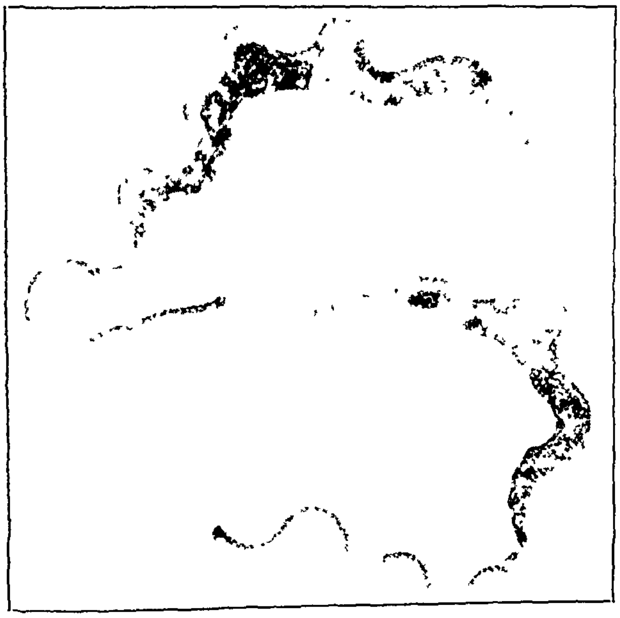

Fig. 3. Photograph of trypanosome of Mauritian surra, from blood of mouse. Preparation stained by Romanowsky-Nocht method. Magnification. 3,000 ×.

Some time ago we obtained, through the courtesy of Dr. Mesnil of the Pasteur Institute, a number of preparations made from the heart blood of a mouse infected with the surra trypanosome brought from the island of Mauritius. A comparison of the preparations having this origin with one from the Philippine Islands shows that the two organisms are quite unlike. In making this comparison the large Zeiss microphotographic apparatus was used to advantage. The individual trypanosomes were studied on the ground glass plate at a suitable magnification, such as 3,000 diameters. Microphotographs taken at this magnification were very useful for measurements and other studies. The length of a trypanosome was ascertained by tracing a string along the border opposite the undulating membrane, from end to end, and then laying this off on a ruler. At a magnification of 3,000 diameters a micron corresponds to 3 mm. It is consequently possible to measure the length of a wavy object in this way more accurately than with an eyepiece micrometer. The total length of the Mauritian trypanosome (see Fig. 3), was on an average 33 μ; the free flagellum was 13 μ, while the width, not counting the wavy expansion of the undulating membrane, was about 1.5 to 1.7 μ. The total length of the Philippine trypanosome (shown in Fig. 4) was from 22 to 25 μ; that of the free flagellum was 8 to 10 and the width was from 1.3 to 1.7 μ. A marked difference, therefore, exists in the lengths of the individuals and of their free flagella. Moreover, the free end of flagellum in the Mauritian trypanosome is enlarged, whereas that from the Philippines shows no such peculiarity.

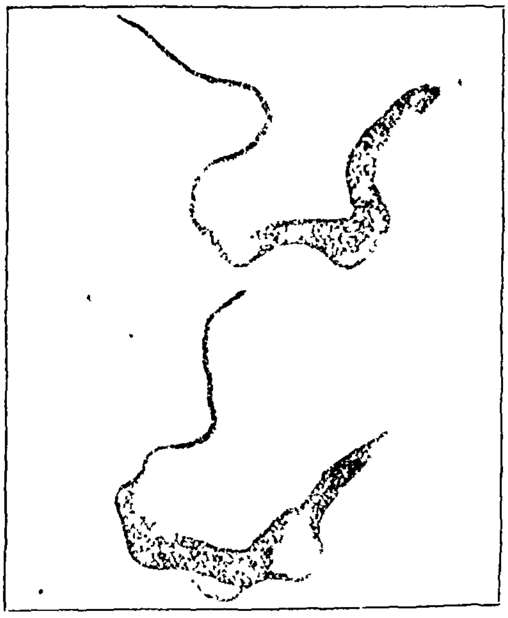

Fig 4 Photograph of trypanosome of Philippine surra from blood preparation Magnification. 3,000 ×.

An even more marked difference can be seen in the shape and distance of the centrosome from the end. Thus, in the Mauritian trypanosome this distance measures 3.3 to 4 μ, while in that from the Philippines it is only 1 to 1.6 μ. In the latter case the centrosomes were nearly all elongated preparatory to division. The heavy printing of the photograph, necessary in order to bring out the faint posterior end, has concealed the centrosome in the lower individual.

The undulating membrane was more developed in the Mauritian trypanosome than in that of the Philippines. In the former it shows four distinct waves which are very suggestive of *Tr. brucei*. In the Philippines trypanosome two or three less marked waves represent the undulating membrane.

Another point to which attention may be called is the presence of heavily stained granules in the anterior half of the Mauritian trypanosome. The posterior half of the body is quite free from these bodies. On the other hand, the Philippine trypanosome stains heavily in the posterior two-thirds.

Obviously too much importance must not be attached to comparisons made under these conditions, especially since the Philippine preparation was stained before it was sent. The observations given seem to indicate that they are two distinct organisms. The proof of this view can be supplied in part by the study of preparations made from the same kind of animal, such as the white mouse or white rat, obtained from different regions where surra is said to exist. A positive demonstration, however, can be made either by the immunity experiment such as has been done by Laveran and Mesnil in their studies on nagana, caderas and the Mauritian surra, or by the cultural method which we have employed.

CONCLUSIONS.

Summing up the main facts presented in this paper we may say that:

1. The trypanosome present in the Philippine surra can be cultivated artificially.
2. Attenuated cultures of this organism can be obtained as in the case of *Tr. brucei*.
3. This trypanosome is differentiated by its cultural characteristics from *Tr. lewisi* and from *Tr. brucei*.
4. The Philippine surra is, therefore, a distinct disease, different from nagana, and this observation confirms the work of Laveran and Mesnil on the non-identity of nagana and the surra of Mauritius.
5. The morphologic differences between the Mauritian and Philippine trypanosomes suggest the probability that these organisms are distinct species and hence that the term "surra" covers a group of closely allied diseases.

A CONSIDERATION OF SPEECH DEFECTS.

JAMES M. BROWN, M.D.

CHICAGO.

In laryngologic practice attention is frequently directed to cases of defective speech, and it is hard to realize how so important a branch of medicine is almost wholly ignored by the profession. The treatment of these distressful ailments is left, with few exceptions, to the advertising quacks, each of whom has his separate guaranteed quick method, which, on investigation, has been proved unsuccessful. All forms of speech defects, known by various terms as dyslalia, magilalia, lallamania, balbuties and psellism, have been generally classified as stammering and stuttering, with the exception of lisping, which is the most difficult of speech defects to correct. Considerable ignorance of this subject prevails among those who have the care of children, and in children defects of speech are comparatively common. Speech defect is usually observed first between the ages of five and fifteen, and is productive of much distress, and often results seriously. The average person is born with all the organs of speech necessary for correct articulation. but some have a physical defect which may interfere with articulation, or they may be afflicted with the disease which will obstruct the proper course of articulation.

Notwithstanding the nervousness which is manifested by the majority of stammerers, they are rarely persons whose nervous symptoms are impaired. The nervousness is often associated with speech. more as a result and not as a cause. as we are prone to believe. Heredity has been proved to take little part in the etiology. The defect may be considered to be more of a habit, and often can be prevented by proper training in childhood.

The paralytic defects of speech that are due to lesions of the medulla involving the co-ordinate centers, or the nuclei of the origin of the nerves concerned, and known as glosso-labio-laryngeal paralysis, are of a progressive order. The author agrees with Potter, who is of the opinion that no medical investigation of this subject is complete without reference to the opinions of Hippocrates, Aristotle and Galen, each of whom made many observations concerning stuttering; but which were more curious than valuable. Hippocrates maintained that there existed among stutterers a chronic diarrhea, and he "dilated on the cure by varices, the cure resulting in suppurating ulcers." Aristotle, on the other hand, ascribed the defect to the tongue, while Galen believed it to be due to "moisture" of the brain and "muscular debility" from cold.

The subject of speech defects was considered very early, as is shown by the interesting observations of the historically famed Greeks, or even before them, as it is said that Moses was afflicted with a speech difficulty, and, with few exceptions, most writers advance the opinion that the tongue is the most frequent cause of the affection, due either to an abnormality or defective use of it. Santorini, in 1705, attributed the cause of defective speech to the abnormal size of "two holes in the middle region of the palate," meaning the palatine canals. Darwin, in 1800, ascribed stuttering to interrupted association of movements in the organs of speech caused by sensations or emotions. Kussmaul, in 1879, defined stuttering as a laloneurose or impairment of speech arising from the spasmodic action of the nerves, including stammering and aphthongia, which is a peculiar form of aphasia due to spasm of the muscles supplied by the hypoglossal nerve.

In analyzing the views of older authorities, we may divide them into three classes:

1. Those who believed the cause of defective speech to be the tongue, tonsils, larynx and palate.
2. Those who held the theory of psychical causation, and who generally aimed at education of the will power to overcome the defect.
3. Those who considered the essential causal feature to be a deranged nerve center, or lack of strength in the co-ordinating powers.

The more modern authorities on this subject seem to consider the various causes that have been enumerated, but they pay particular attention to abnormalities of the upper air passages and their correction, followed by proper respiratory and vocal exercises.

Among the primary causes first observed in children are fear, timidity, a fall or ill treatment. Imitation lies at the bottom of many conditions, as in childhood this faculty seems to be more highly developed than at any other period of life.

Dr. G. Hudson Makuen, the foremost American authority on this subject, states that "operations have been performed on the tongue for the cure of stammering, but have fallen in repute for lack of rational and scientific reasons." He reported a case before the Philadelphia County Medical Society of unusual interest. The patient had never uttered four syllables intelligently. Examination showed a congenitally short genio-hyo-glossus muscle of the tongue, which was divided, and after suitable instruction the patient was able to recite better than the average person. He reported a series of 200 cases of speech defects that he had observed, 140 of which were stammerers, the remaining 60 representing different varieties of vocal and speech defect. Ninety-five per cent. of the cases were males; their ages ranged from 6 to 53 years; 32 per cent. had stammered from the inception of the speech development; 52 per cent. began between the ages of 3 and 10 years; 2 at 11 years; 1 at 12; 1 at 14, and 2 at 15 years of age. Whooping cough, measles, scarlet fever, diphtheria, smallpox and a hereditary history of consumption and insanity were important causal factors in several cases.

The same author also reports an interesting case which was due to the presence of adenoids. A patient, who was recently under the writer's observation, showed marked improvement after the removal of hypertrophied faucial tonsils.

The continuous production of voice is the essential of speech. To accomplish this, a strong, unbroken stream of sound is necessary, and no mouth action should be allowed to interfere with the throat sound. There is no trick or particular method that is applicable for the treatment of all cases. If possible, the cause should be first ascertained, and then treatment instituted for ultimate relief. In many cases, the main point to be remembered is the easy passage of air, with attention to the proper placing of the voice, that being the material of speech, and should not be impeded in any way. Training for continuous production gradually enables one to become familiar with all vocal elements. Self-observation and control, eradication of the spasmodic actions, together with patience and perseverance, will, in many instances, permanently overcome the distressful, embarrassing impediment in speech.

Special Article.

THE ARMY MEDICAL SERVICE.

IV.

(Continued from page 1354.)

The work of medical officers of the Army is directed primarily toward the maintenance of the health and physical and moral vigor of the personnel, and secondly, toward the care of the sick and wounded. Of the latter work, which includes the administration of military hospitals, the furnishing of medical and surgical supplies, the providing of sick diets, and the directing of the nursing and professional care of the sick, the Medical Department has complete control. A medical officer's duties, therefore, are of three kinds—sanitary, administrative and professional. On entering the service his medical education presumably has prepared him for the latter duties, but before he can become an efficient medical officer he has much to learn. What special knowledge and military training is necessary may be seen by glancing at the course of instruction in the Army Medical School. The subjects of the curriculum not usually covered in medical schools are as follows: Military hygiene, military surgery, military medicine, equitation, hospital corps instruction, duties of medical officers in war and in peace.

The last named branch is regarded as the most important. Its scope is shown by an outline of the subjects covered during the last session of the school:

DUTIES OF MEDICAL OFFICERS IN WAR AND IN PEACE.

(*a*) The organization of the Army.

(*b*) The rank and precedence of officers and non-commissioned officers.

(*c*) Responsibilities of command.

(*d*) Military discipline, its necessity, its object, and the means of imparting it.

(*e*) The duties of the Medical Department.

(*f*) Medical department administration—covering the subjects of military correspondence, property, pay, clothing, rations, enlistments, sanitary reports, sick and wounded reports, reports relating to the personnel, and army regulations in so far as they relate to the medical officer and to his administrative duties.

(*g*) The organization and administration of military hospitals.

(*h*) The duties of post surgeons.

(*i*) Military justice.

(*j*) Customs of the service.

(*k*) The duties of the Medical Department in the field—the work to be done and the organization and equipment necessary to perform it; the principles on which field medical organization is based; the organization, equipment and duties of each field unit on the march, in camp, and during an action; the organization on the lines of communication and at the base; the administrative duties of medical officers in the field; practical instruction in field work.

When the Army takes the field, the duties of the Medical Department become greatly increased in importance and in scope, and as with other parts of the Army, it is only by careful preparation in time of peace that success in war is to be expected. To guard the health and physical and moral vigor of the troops is the first duty of the medical officer, and his training and study should be such that he is prepared to anticipate and successfully to meet the problems which may confront him in camp and in campaign. Next to his duties as a sanitary officer comes that of the care of the sick and wounded. From the time a man falls in action or is taken ill until he is cured, is discharged, or dies, the Medical Department is charged with his care and transportation, at dressing stations, in field hospitals, ambulances, hospital trains, hospital ships, base hospitals, and convalescent camps. This work requires thorough organization, proper equipment and careful training of the personnel.

On entering the Medical Department, the young medical officer has the rank, pay and allowances of a first lieutenant of cavalry, and after five years' service becomes a captain, provided he passes the required examination for promotion; above the grade of captain promotion is by "seniority", i. e. promotion occurs by reason of length of service, the senior in one grade being promoted when a vacancy occurs in the next higher grade. Promotion to the grade of major is, however, like that to captain after examination.

A medical officer's status as regards privileges of rank, pay, and emoluments, is the same as that of other officers. A commission in the Army is for life, provided service and conduct are satisfactory. Beside the actual pay, the emoluments and privileges add much to the value of a commission. An officer is entitled to quarters at military posts, which he has the privilege of selecting according to his rank. At stations where no quarters are provided, he receives commutation in money therefor. His home and grounds are cared for and kept in repair by the government, without expense to himself. He has the privilege of purchasing from the government, at cost price, commissary supplies, fuel, articles of bedding, clothing, and field equipment. In money value these emoluments are believed to equal one-third of an officer's pay. Stables and forage are provided without expense for the horses allowed mounted officers. An officer is entitled to one month's leave of absence each year on full pay, which may accumulate until four months have become due. Pay does not cease during illness, and officers and their families are entitled to medical attendance and supplies. An officer disabled while in the service is retired on three-fourths pay, and his retirement on the same pay is compulsory on reaching the age of sixty-four years.

Length of service adds materially to an officer's emoluments and pay. Beside the increased pay of the higher grades, an officer's pay is increased 10 per cent. for each five years of service, until 40 per cent. has been added. By reason of increased rank he is entitled to larger and more desirable quarters, or to additional commutation therefor. In addition to the advantages here mentioned, in the Medical Department increased rank means more important duties and more desirable stations. On change of station, officers receive seven cents per mile for the distance traveled and free transportation of baggage, horses and household effects within a certain limit.

The pay of all grades of medical officers here given is that of the grade alone and does not include the increase for length of service,[1] except in the case of a brigadier general.

	Per Year.
First lieutenant	$1,600
Captain	2,000
Major	2,500
Lieutenant colonel	3,000
Colonel	3,500
Brigadier general	5,500

There are unusual opportunities in the medical service of the Army for independent work and investigation. At nearly all stations medical officers have at their disposal well equipped operating rooms, bacteriologic and chemical laboratories, and medical libraries. The libraries are kept up to date by frequent additions, and books on special subjects may usually be obtained on application to the surgeon general. The leading military and medical journals reach all posts. The post hospital constitutes for the medical officer an almost independent jurisdiction, as he directs and controls most matters relating to it. The surgeon is, however, subordinate to the post commander, the latter being held responsible for the efficiency of every part of his command. Medical officers frequently serve on investigating boards of various kinds and are frequently detailed to make special investigations in this country and abroad. The boards appointed to investigate the prevalence of typhoid fever in camps in 1898, and to investigate yellow fever in Cuba, in 1899, were composed of medical officers. The findings of these boards mark epochs in the advancement of preventive medicine and have become matters of history.

The list of medical officers who have won distinction in various fields is a long one, and it is one of which the medical profession and the Army is proud. In this connection, the names of Beaumont, Tripler, Jonathan Letterman, Billings, Sternberg, Reed, Gorgas, and Carroll may be mentioned.

Beside the professional opportunities offered by it, which are many and ought to be satisfying to the average medical man, army life is an attractive one. Patriotism, the military spirit, and *esprit de corps* are encouraged and stimulated and a high standard of honor and of gentlemanly conduct is insisted on. Military discipline and orderly routine conduce to contentment. In the service, many of the worries and uncertainties of civil life are unknown.

Where everything is ordered with the one regard of advancing the soldier's physical well-being and contentment, athletic and other sports find prominent places in both the Army and the Navy. At many stations excellent fishing and shooting are to be found. Practice marches and autumn maneuvers bring most infantry, cavalry and field artillery garrisons into the field for several weeks each year.

Change of station and field of work with the opportunity for travel thereby afforded, may be classed as advantages which are not enjoyed by the average medical man. A medical officer in a few years' service will have seen much of the world and have served in many interesting parts of his own country. Service at stations in the east, west, and abroad is equalized as far as possible. Frequently an officer is given the opportunity of naming the station he most desires among those where vacancies exist. The present tour of foreign service is three years, during which an officer receives 10 per cent. increase in pay. As it is probable that there will be one-third or one-fourth of the Army serving abroad, it would seem that two-thirds or three-fourths of the medical officer's service will, in the future, be in the United States.

As the medical officer increases in rank, his duties become more important and his stations more desirable. Beside the usual stations of medical officers at garrisons and posts, there are a number of detached and independent stations away from troops, such as the large general hospitals at the Presidio of San Francisco, at Fort Bayard, New Mexico, at Hot Springs, Arkansas, at Washington, D. C., and two or three in the Philippines; companies of instruction of the Hospital Corps, two of which are now in existence; the Army Medical School, at which there are on duty several medical officers as instructors; the Army Medical Museum, in Washington; the Surgeon General's Office; the large medical supply depots at New York, St. Louis and San Francisco; the stations as chief surgeons of military departments, of which there are ten in the United States and three abroad.

In time of peace appropriate duties for medical officers above the rank of major are those of chief surgeons of departments, medical supply officers and commanding officers of general hospitals. Those of the rank of major are usually the senior medical officers at large posts, while those lower in rank may be assistants at the larger posts and hospitals or in medical charge of the smaller ones.

Should legislation which is now pending be enacted, the important advantages of more rapid promotion and an increase in the grades of colonel, lieutenant colonel and major will add greatly to the attractiveness of the medical service of the Army.

(To be continued.)

Attempts at Extrabuccal Oxygen Administration.—Salomon reports from von Noorden's clinic that all attempts to supply oxygen to the system by the rectum failed. The results were more favorable from baths impregnated with oxygen. The gas was conducted into the bottom of the bathtub full of warm water, similar to the arrangements for carbonated baths. In 2 out of 7 subjects thus treated the amount of oxygen consumed from the respired air was materially diminished. In his communication to the *Zeitschrift f. diät. und physik. Therapie*, vii, 10, 1904, he states that no effect on the respiratory consumption of oxygen was perceptible when the subject was placed in an air-tight bag into which the oxygen was conducted. Similar trials with carbonic acid gas also proved negative.

---

[1] The 10 per cent. increment for length of service is called a "fogy," and an officer of twenty years' service is said to have four fogies, hence the expression an old fogy. The pay of a major with four fogies is, for example, $3,500.

INSTRUCTION IN PSYCHIATRY.

The ignorance of the laity as to what constitutes insanity is proverbial. A raging maniac is the only popularly accepted type of this most subtle ailment whose manifestations include every variety of expression. The lack of knowledge on the part of not a few members of the medical profession is also marked. Those who have had the opportunity of reading the hospital history sheets of insane patients will bear us out in this statement. There are, at a conservative estimate, 150,000 insane patients in public institutions, and it is certain that only a small proportion of these are ever seen by the great alienists at any stage of their disease, while the number who are seen by them in its early and partially developed period must be even less. For the general body of the people, exclusive of the very wealthy, the only hope of any preventive medical treatment for threatening mental disorder must always lie with the general practitioner. As a rule, the family physician is a man of good ability and in most subjects his training in the better medical schools keeps pace with the most modern developments of medical science, but this can not always be said to be true of his training in psychiatry. An examination of the courses of study of the principal medical schools in this country reveals only too plainly that the fountain must indeed rise higher than its source if the general practitioner is to know much of mental diseases.

The latest bulletins of twelve of the leading medical schools show that psychiatry is a department which in most instances has lagged behind the other departments and has failed to keep pace with the advances of modern medical science. In the University of California, no instruction in psychiatry is offered to undergraduates. Other schools content themselves with a course which takes only a few hours during part of the senior year. Thus Cornell devotes fifteen hours to the teaching of this branch; Northwestern University Medical School, Chicago, offers one lecture a week for one-half of a semester. In Rush Medical College, Chicago, the subject is combined with neurology and the course counts as one-fifth of a major, which makes it only one-twentieth of the amount of work required in the department of medicine. Another school which treats psychiatry together with neurology is the Medical College of the University of Minnesota. It is possible that they order things better in these two schools, but usually such a course virtually means nine-tenths neurology and one-tenth psychiatry. The course in the University of Minnesota is required, but in Rush it is optional—a student may graduate without having had any instruction in psychiatry.

It is not only a question of the time allowed to each subject, but the difference is equally striking between the methods employed in this and other subjects—as, for instance, surgery. The teaching of surgery is carried on almost entirely by means of demonstrations and clinics, while the teaching of psychiatry is apt to follow the antiquated method of didactic lectures. The College of Physicians and Surgeons, Chicago; Northwestern University, Chicago, the University of Pennsylvania and Harvard are instances of such schools. Harvard has a course in clinical psychiatry, but it is not required. The University of Michigan, Johns Hopkins University, the College of Physicians and Surgeons, New York; Cornell and the Medical School of St. Louis University all require attendance on the clinics in psychiatry, although in the case of the two last mentioned the amount of work offered is very small. The clinics at Cornell occupy ten hours in all; at St. Louis University, one hour a week for one semester. Johns Hopkins University offers rather more instruction in psychiatry than do any of the other schools thus far mentioned, except the University of Michigan. Aside from didactic instruction, which is quite ample, there are clinical demonstrations in the dispensary and in the City Insane Asylum. Considering the large number of these schools which are situated within practical distance of great insane asylums, it seems strange that so few of them have arrangements for the utilization of this valuable clinical material.

The department of psychiatry of the University of Michigan is an instance of co-operation between the state institutions and the state medical schools which is plainly in the line of good public policy. The superintendents of the state hospitals for the insane are appointed special lecturers on psychiatry to the senior class, and the students are taken to the asylums for clinical instruction. There is a system of internes in the hospitals—the men usually being graduates of the university. The psychopathic hospital for acute and incipient cases, which the university has just now finished, after the example of German universities, is the first one of its sort in this country and is especially valuable for teaching purposes, as the cases seen at the asylums are inevitably chiefly of the chronic type.

We hear much of the cost to the state of every death from tuberculosis, as this disease is most fatal during the working period when each life is estimated as being worth to the state five thousand dollars. Now it must be remembered that the average insane patient is not only equally a loss to the community at the time of his commitment to an asylum, but in addition he is from that moment a heavy item of expense. It is estimated, for instance, in New York that the average chronic insane patient costs the state six thousand dollars for maintenance, which would indicate that the cost of each case of chronic insanity (even when the very important items of family pauperism and of inherited mental defect are ignored), is more than twice that of each fatal case of tuberculosis.

The increase of insanity has become so marked and the expense of caring for its victims is so heavy a burden in every state that the necessity for some preventive measures is becoming evident even to the lay mind. Such preventive measures must be directed to the care of incipient and acute cases, and for this we need numerous and well-equipped psychopathic hospitals and numerous and well-equipped alienists among our general practitioners. For the first we must look to the general public, whose co-operation is absolutely essential for the foundation of such public and private institutions. For the second we must look to the medical schools, for it is largely through a radical change in the old-fashioned and inadequate methods of teaching this subject that we may hope to lessen the waste of life and cost to the state caused by insanity.

THE SIGNIFICANCE OF THE GLYCOGEN REACTION IN THE BLOOD.

Originally described by Gabritschewski in 1891, this reaction seems to have been overlooked until 1902, when several observers, notably Locke and Cabot[1] in this country, again called attention to its value. In 1903 Locke published a further communication,[2] in which he quite sharply defined the advantages and limitations of the test. Quite recently Lovell Gulland[3] has published the results of a long series of observations which completely substantiate the conclusions of Locke.

The test is such a simple one that it seems peculiar that it has not come into more general use. In order to make the test, a blood smear is placed face downward on a drop of a thick gummy solution of iodin and iodid of potash in gum arabic, and, after being allowed to remain for a minute to allow the action of the iodin to take effect, the excess of the solution is removed by pressure on the cover-slip or by means of filter paper. The specimen is then examined with the oil-immersion lens. In normal blood all of the cells take on a uniform bright yellow color, the nuclei of the leucocytes staining more lightly than the protoplasm and having a refractive appearance. When the glycogen reaction is present, small or large brownish granules are to be seen in the protoplasm of the polynuclear leucocytes, or else these cells take on a diffuse brownish tint. Generally, too, large or small brownish masses are to be seen outside of the corpuscles, so that we speak of an extracellular and an intracellular reaction. Very rarely other forms of leucocytes beside the polynuclears show the reaction, but this occurs so infrequently that it has no practical bearing on the test.

The glycogen, or, as Locke prefers to call it, the iodin reaction, occurs in three classes of cases—in cases with respiratory disturbances, in certain cases of anemia and in toxemias, either of chemical or bacterial origin. In the cases of respiratory disturbance, whether due to stenosis or cardiac or non-inflammatory lung disease, the reaction is usually not very marked, and disappears rapidly on the disappearance of the respiratory symptoms. The reaction is not usually present in chlorosis and mild secondary anemias, but only in severe secondary and pernicious anemia, and in acute and late leukemias. Gulland is inclined to think that the anemia *per se* is not the cause of the reaction in these cases, but that it is due to the toxemias or bacterial infections which are so common in such conditions. The reaction occurs most characteristically in cases of suppuration and bacterial infection, though it may occur in chemical toxemias as uremia or diabetic coma. It is of the greatest value in septic diseases, which are usually accompanied by a leucocytosis, but in which this sign is not infrequently lacking. In appendicitis, for example, the observations of both Locke and Gulland show that during the attack the reaction is never absent, and in many cases with obscure symptoms and without leucocytosis, its presence is of the greatest diagnostic value. Even in cases in which the diagnosis is not in doubt, the intensity of the reaction may settle the important question of the presence of pus. According to Gulland, the test may also be of value in the diagnosis of deep-seated pneumonia with few physical signs, in differentiating serous pleuritis (which does not give the reaction) from empyema, in differentiating tubercular from other forms of meningitis, and in separating cases of gonorrheal arthritis from true rheumatism. In cases of suspected strangulated hernia, the test is of value, as it is positive in cases where gangrene is present, and negative when the intestine is merely obstructed. As Locke says, and Gulland confirms the statement, the presence of this reaction always indicates that the patient is very sick.

This reaction, like all others, requires a certain amount of experience before the findings can be accurately interpreted, but it is so easily applied that it would seem worthy of a much more extended use than it is receiving at present.

MODERN OPERATIONS FOR THE RADICAL CURE OF HERNIA.

Twenty years ago, when an eminent professor of surgery was asked his results from operations for the radical cure of hernia, he replied that they were so poor that he had entirely given up operating except in cases of strangulation or in other dangerous or disagreeable complications. That probably represented the standpoint of leading surgeons of that day, but with modern methods and asepsis the operation is so successful that in most American hospitals all patients with hernia coming for consultation are advised to undergo operation. While this position is taken by the leading surgeons of the best hospitals, the truss-makers still continue to thrive, and several standard text-books may still be found in which considerable space is devoted to the description of trusses and their uses.

[1] Journal of Medical Research, vol. vii, No. 1.
[2] Transactions of the New York State Medical Society, 1903.
[3] British Medical Journal, April, 1904.

We believe that if general practitioners understood the safety and satisfactory results of the radical cure of hernia, the public would be more rapidly educated to seek relief for this very common trouble, as has been the case with the treatment of appendicitis. The best idea of what results are being obtained is gained by a study of the results of operators of wide experience whose familiarity with the anatomy of hernia and the best methods makes them specially fitted to operate successfully. A recent article by Hilgenreiner,[1] an assistant in Wölfler's clinic in Prag, reports eight hundred and twenty-eight operations performed since 1895. The question of first importance is, of course, the danger to life, and the extremely low death rate of less than one in four hundred operations shows how safe the operation may be in the hands of careful surgeons. The cause of death mentioned was post-operative pneumonia, from which the patient died on the tenth day after operation. Experience in eight hundred cases reported by Goldner,[2] from Hochenegg's clinic in Vienna; four hundred and fifty-nine cases reported by Bloodgood,[3] and by Coley of New York in nearly a thousand cases, show that the death rate can be brought certainly to less than one in two hundred cases.

The question of next greatest interest is the permanency of cure, and this depends on a number of factors. In Wölfler's clinic there have been no recurrences in children under fourteen years of age; also no recurrences in inguinal hernia of women. Bloodgood has shown the importance of the strength of the conjoined tendon, finding no recurrences in two hundred and sixty-four cases in which the tendon was wide and firm, but a high percentage of recurrences in cases of a weak or obliterated conjoined tendon, when the rectus muscle was not transplanted to cover the defect. Wölfler was the first to adopt transplantation of the rectus muscle, and he uses it in all cases, while Bloodgood finds it unnecessary, except in cases in which the conjoined tendon is weak or obliterated. Another matter, the importance of which was first pointed out by Bloodgood, is the size of the veins of the cord. A considerable percentage of recurrences in cases with enlarged veins lead to the adoption of excision in suitable cases. Great weakness of the muscles of the abdominal walls, aside from the conjoined tendon, may necessitate the use of the cremaster muscle in closure, as Halsted[4] has practiced successfully in many cases. Halsted states that since June, 1892, not a single recurrence has followed his numerous operations for the radical cure of hernia, and in all cases reported by Bloodgood the percentage of recurrences was a little over 6 per cent. The results from Wölfler's clinic are almost as good as this, only a little over 7 per cent. of recurrences being recorded. With the use of rubber gloves at the Johns Hopkins Hospital, the percentage of infections has been reduced to a fraction of 1 per cent., and Hilgenreiner reports similar improvement in Wölfler's clinic since the routine use of operating gloves was adopted. The method of operation, no doubt, has a decided influence on the success of the result, though probably any of the best modern methods in the hands of experienced and skillful operators will be followed by satisfactory results.

With the inconvenience and interference with physical exertion which comes from wearing a truss and the danger of strangulation, it would seem that those who are afflicted would be glad to take the slight risk which attends the modern operation. Even in old age and with serious affections of the heart or lungs, the operation need not be considered contraindicated, for these can be operated on under local anesthesia.

THE TREATMENT OF ULCER AND CANCER OF THE STOMACH.

The amount of recent literature on ulcer and cancer of the stomach indicates that the importance of these affections is being widely recognized. This is due not only to the frequency and ubiquity of these conditions, but also to the unsatisfactory results of the treatment hitherto in vogue. Rational medical treatment based on pathology and symptomology seems to have reached its full development. At any rate, there has been no marked recent progress, and the prospects are not encouraging. Internal medicine has confessed itself unable to diagnose cancer of the stomach in average cases early enough for satisfactory or even justifiable surgical intervention, and, therefore, regards this condition as hopeless. In the treatment of gastric ulcer, internists accomplish many immediate, but far fewer permanent cures, and are unable to prevent or control the frequent complications. On the other hand, surgery, having successfully relieved many conditions previously regarded as hopeless, is gradually finding a wider sphere of legitimate application.

In order to shorten the long periods of incapacity and distress in cases which do not respond readily to internal treatment, as well as to eliminate the serious dangers of immediate and remote complications, surgical treatment should be instituted. As it is almost equally important that this should be done while the patient's condition still permits an operation of choice, there is urgent need for the early recognition of the indications for radical measures. Bedside and postmortem observations alone are nearly as incapable of solving this problem as they were of settling the question of the treatment of acute abdominal affections. In these latter conditions surgery amply demonstrated the necessity and wisdom of obtaining its working pathology in large part from the living body, for only in this way were sufficiently early diagnoses made possible. Similar progress is now being made in the diagnosis and treatment of gastric diseases, but in these affections the immediate operative results are insufficient for the determination of the best procedures. Careful and prolonged subsequent observations, obtainable only through the co-operation of the surgeon and the physician, are required to make the progress healthy and more rapid.

[1] Beitrage zur klin. Chir., 1904, vol. xli, p. 373.
[2] Archiv für klin. Chir., 1902, vol. lxviii, p. 1.
[3] Johns Hopkins Hospital Reports, 1899, vol. vii.
[4] Bulletin of the Johns Hopkins Hospital, 1903, vol. xiv, p. 208.

The outlook for better results from the radical treatment of cancer of the stomach is bright compared to the apparent hopelessness of other measures. Now that the mortality from pylorectomy is no longer prohibitive (15 per cent.), and there is a reasonable chance of cure (8 per cent. are said to go beyond the three-year limit without sign of recurrence), there should be less opposition to the operation.

The greatest obstacle to progress in the treatment of gastric carcinoma has always been the delayed diagnosis, and will always be so, as long as the present methods are retained. Exploratory laparotomy has never been given a fair trial as a means of early diagnosis, having been practically restricted to the determination of the eradicability of the lesion. A suitable incision can be made under local anesthesia with little discomfort, practically without danger, and causing only temporary disability; and it would seem that it should be resorted to when there is a reasonable suspicion of the existence of a carcinoma. Unquestionably the early recognition of cancer, particularly when grafted on an ulcer, would be extremely difficult, and consequently benign lesions might be excised. Still this would be a pardonable error, removing the commonest cancer-bearing area, just at the time and under the conditions of greatest danger.

In those cases in which a cure is not obtained, death usually results from metastases—seldom from local recurrence. Life is on the average longer than in the unexcised cases, and for a time, at least, there is mental and physical comfort. In the face of this evidence, it seems hardly justifiable to deny to any individual the possibility of a cure or the probability of a longer and comfortable life, when the horrors of the only alternative are only too well known.

LEPROSY.

While there is no good reason for doubting that leprosy is dependent on the activity of the bacillus isolated by Hansen, there is ground for believing that infection is favored by certain predisposing influences. It may be that more or less intimate contact is necessary for the transmission of the disease, but over and above this it seems not unlikely that the susceptibility may be in some way related to the general nutrition of the individual. That there is anything in the diet that specifically gives rise to leprosy is not commonly believed, but that some inadequacy in the food may be of importance in this connection is the view taken by Dr. W. D. Neish and Mr. T. J. Tonkin,[1] in the course of a communication dealing with the question of leprosy in Jamaica.

These observers point out that the leprous areas of the world coincide with those in which the diet of the inhabitants is characterized by a deficiency of nitrogen, and that the prevalence of the disease diminishes in proportion as this deficiency is supplied. Thus, in Jamaica, the number of lepers has diminished in the course of forty years from 800 to about 300, while the population has almost doubled—there being at present about four lepers to every 10,000 of the population. This diminution in morbidity is coincident with a gradual improvement in the native diet. In addition, the great improvement observed in cases of the disease when a liberal diet is provided is especially noteworthy. This is, in fact, considered a most important feature of the treatment, an ample supply of bread, milk, meat and peas being given in addition to the national foods.

One of the most successful measures in the treatment of the disease consists in the subcutaneous injection of mercuric chlorid, which was employed in about 100 specially selected cases. One-quarter grain each of mercuric chlorid and sodium chlorid, dissolved in 20 minims of distilled water, was injected twice weekly through a platinum or iridium needle deeply into the muscles of the back or the buttocks. The injection is painful, and is followed by considerable induration, the pain persisting for from two to four hours and the swelling for a week.

The treatment in general is roborant and hygienic. Cleanliness is insisted on, and patients are made to bathe at least twice weekly. Suitable literature is provided for those that can read, and games and sports for those able to indulge in outdoor exercise. Plays, readings and concerts are given in the evenings. There is a school for the children and work for the older patients. Segregation is not compulsory, except for pauper and vagrant lepers.

The prevailing note in the communication under consideration is one of conservative and healthy optimism. As will be seen, much can be done not only to prevent the disease by hygienic means, but also in the way of amelioration and cure in the individual case—naturally the more the earlier the disease comes under observation and is subjected to treatment.

WELTMER DOWNED AGAIN.

In our medicolegal department we have already noticed the decision of the Missouri Supreme Court against Weltmer and others for malpractice. It would appear from this that the court disregarded the plea of the healers that they were not physicians and that they were not treating patients under the ordinary rules. The court also ruled out their objection that the testimony of ordinary physicians was not competent in their case. The decision was a sensible one, and all the more satisfactory since it dealt with a Missouri institution. It settled the question in that state as to the liability of self-styled magnetic healers in the care of disease. The state motto of Missouri is "Salus populi suprema lex esto," which a humorist liberally translated "the law shall not stand in the way of the safety of our people." The Missouri Supreme Court, on the other hand, takes the more rational view of the case. It believes in the protection of the people even against those who claim to heal only by the special power of mind. We hope that there will be more decisions of this kind.

---

[1] Bristol Medico-Chirurgical Journal, March, 1904, p. 1.

THE REED MEMORIAL.

We are glad to learn that the Reed Memorial Association has been regularly incorporated. An appeal will soon be sent out to the public for a memorial fund to commemorate the splendid work of Major Reed and to aid in the support of his family. During the meeting of the American Medical Association at Atlantic City it is proposed by the committee appointed last year to bring the matter before the members so that they may show their sympathy in a practical way. When the profession has led the way, the public will surely follow.

THE MEDICAL PROGRESS OF TWENTY-FIVE YEARS.

Some interesting figures recently published[1] show the reduction in mortality for some of the more frequent diseases in the last twenty-five years. The mortality per one hundred thousand, in the cities of Germany having a population of over fifteen hundred, during the years 1877-81, is compared with that during the years 1897-01. Nearly all the diseases which we now know to be infectious show a marked decrease in their mortality rate. Without mentioning in detail all the diseases cited, some of the figures may be quoted as being of special interest. Thus, in the first period (1877-81), thirty-seven times as many people died of smallpox as did in the last period (1897-01). During the first period four times as many people died of typhoid fever, twice as many of puerperal sepsis, one and one-sixteenth as many of pulmonary tuberculosis, and over three times as many of diphtheria. The only class of infectious diseases which showed an actual increase in mortality were the acute intestinal diseases, aside from typhoid. The authors consider the decrease in mortality to be due to a variety of causes, of which the most important is the general improvement in the hygiene of cities; good water supply, good sewerage, wider streets, and regulation of tenement building. In individual diseases, other factors come into play, as the discovery of antitoxin in diphtheria. While these statistics refer to German cities, they can probably be applied with reasonable accuracy to American cities, though we are free to admit that the needed sanitary reforms in large cities are more slowly and perhaps less efficiently carried out in this country under present political conditions than they are in Germany under a paternal government.

THE RED CROSS SOCIETY.

The recent reorganization of the Red Cross Society of the United States greatly increases the prospects of its future usefulness. Notwithstanding the acknowledged merits of Miss Barton, her age and her dependence on others have made it probable that she was not a suitable head. It is a little unfortunate that she did not recognize this herself. The withdrawal of President Roosevelt as an indorser of the organization was a sharp reminder to the public of the condition of affairs and probably aided in the present movement. The new Red Cross Society will be, it is said, an institution backed by the Government and with arrangements for local state branches. The accounts of this society are to be audited by the auditor of the War Department and annual reports will be made to Congress. The business methods which have been so long criticised will be thoroughly revised. The usefulness of such a society in times of stress has been well shown in the present Russo-Japanese war, there being on both sides an efficient organization which is doing much to aid in the mitigation of some of the horrors of war. If our own country had been suddenly involved in hostilities with another power little dependence could have been placed in the Red Cross as it has existed for the past few years. We would have been obliged either to reconstruct it or to depend entirely on new resources. The present prospects are that we will in the future have a body capable of valuable service not only in times of war, but in the emergencies of peace to which we are, from the extent of our territory, etc., especially liable.

MEDICAL EQUIPMENT OF WARSHIPS.

The Russo-Japan war is likely to give us some additional points in regard to military medicine. The Japanese have shown themselves to be good scientific observers, and it will not be irrational to suppose that there are also equally competent ones in the Russian service. One rather important suggestive point has already been brought out by the report of Dr. H. D. Wilson of the gunboat *Vicksburg* in regard to the wounded in naval warfare. He was sent to aid in the care of the wounded of the *Variag* after her first engagement with the Japanese fleet and reports that notwithstanding the fact that the ships did not come into close contact and only the main batteries were used, the number of wounded on board that ship, well fitted as she was to care for the ordinary emergencies as it was supposed, proved her arrangements for medical and surgical care entirely inadequate for the occasion. He thinks the result of this engagement shows how impossible it is to attend to the wounded during an engagement between modern ships unless the number of medical attendants is tremendously increased. As at present arranged it would appear that the wounded will have to take entire care of themselves until the fight is over. In a fight lasting not over twenty-five minutes nearly one hundred men were disabled by wounds, and this in spite of the fact that the ships were from three to seven thousand yards apart and the minor batteries not employed. It is evident that under modern conditions naval warfare is not tending toward any great advance in the immediate care of the disabled in battle.

---

[1] [illegible]er med. Wochenschrift, ii, No. 16.

The attendance of hospital ships would seem to be an almost inevitable necessity to any fleet engagement. Their lack even in single ship engagements will be a misfortune.

THE NATURE AND TREATMENT OF SOME FORMS OF SLEEPLESSNESS.

The causes of sleeplessness are varied, but they must all be looked for in some irritative disturbance affecting the central nervous system. The disturbance often is cerebral, cardiac or gastrointestinal in origin, but at times its precise source may not be obvious. Sleep may be affected in several ways, somewhat in accordance with the disturbing influence. In the first place the patient may lie awake for hours and finally fall asleep, as is common in neurasthenics; or he may have no difficulty in falling asleep at once, but awakes early, as is often the case in the aged; or he may fall asleep readily and in a short while be awakened suddenly, usually with a sense of fear and slight oppression of the chest and almost always with palpitation of the heart—this is characteristic of cardiac disorder. Some interesting observations on this last variety are recorded by Dr. Leopold Feilchenfeld,[1] in whose opinion it is to be attributed to weakness of the heart muscle, with derangement of compensation. He has noted that sleep occurs most readily when the patient lies on the left side, but it is likewise terminated most rapidly under the same conditions. The apex beat is extended and displaced to the left, the pulse becomes small and frequent, and symptoms of dyspnea set in. It is probable that transitory dilatation of the heart takes place from interference with the circulation of uncertain character. Sometimes the symptoms develop when the patient occupies the dorsal decubitus. As to treatment, it is to be remembered that sleep may be prevented or interrupted at any stage in accordance with the presence of flatulence, pressure on the heart, cerebral congestion or excessive peristaltic activity. Relief will usually be afforded by free evacuation of the bowels and moderation in diet, especially in the last meal of the day. Insomnia is often a habit and, in cases of neurasthenia especially, the vicious circle must be broken up and sleep induced for several nights in succession. This end may be attained by the administration of small doses of some harmless hypnotic, as sulfonal and the like. Of sulfonal, for example, about four grains may be given two or three times in the course of the afternoon. He even recommends the use of morphin in very small doses to secure sleep at first, but this is an exceedingly dangerous suggestion. There is danger that the last end of the patient may be worse than the first. If the physician has a suitable patient under his complete control and is able to minimize the risk of the procedure, 1/25 grain of morphin hydrochlorate may be given in combination with small doses of digitalis, ¼ grain, given at night. Of course, in addition to the measures indicated other hygienic procedures should be instituted, including especially hydrotherapy.

THE PRODUCTION OF ACID BY THE GROWTH OF PNEUMOCOCCI IN PNEUMONIC SERUM.

The closer study of the reactions of infection has revealed a number of significant phenomena, such as specific bacteriolysis, specific agglutination, specific precipitation. While pneumococci grow equally well in normal and in pneumonic serum, the growth in the latter is characterized by the formation of a voluminous sediment. Rosenow[1] shows that this sediment is due to a distinct precipitation, independent of agglutination of pneumococci, and not produced by rapid growth and death of the cocci. In trying to discover the real cause of this precipitation, Rosenow found that as pneumococci grow in pneumonic serum, there develops a marked acid reaction, whereas pneumococcal growth in normal serum does not change the reaction. The precipitate mentioned is evidently closely connected with the acid production, because it was found proportional to the degree of acidity; because no precipitate forms in heated serum (56 C.) when the reaction remains alkaline, as happens in some cases; because a similar precipitate develops when pneumococci are grown in normal serum, to which has been added some organic acid. Pneumococci also produce acids in the serum of some other febrile diseases, e. g., scarlet fever. In the serum of normal persons, however, they do not change the reaction, judging from Rosenow's large number of control experiments (28). He has made no effort as yet to determine the exact kinds of acids produced in pneumonic serum, except to make out that lactic acid is present. Of course, we are not yet in position to form any idea as to the exact significance of the presence of this acid-producing substance in pneumonic serum. Many interesting questions suggest themselves, as, for instance, whether acid is produced as the pneumococci grow in the lungs and in the blood during the course of pneumonia. It is said that late in fatal cases of pneumonia the blood shows a diminished alkalinity. Rosenow asks whether or not some of the toxic symptoms in pneumonia may not be the result of acid intoxication, and suggests that the favorable results obtained by some physicians from the use of alkalinizing agents might find their explanation along this line. It is as yet too early, however, to make any far-reaching inferences. Other and more diversified observations and experiments must be made first. Pneumonia presents so many complex problems and is a disease of so tremendous importance as few others at the present time, that every new addition to our knowledge in regard to it, especially when it opens up new avenues for investigation, is most desirable.

THE APPLICATION OF A NEW METHOD OF RESEARCH.

We have recently had occasion to refer to the progress in the study of protozoa that has been made by American pathologists within the past two years, which has been remarkable, and which will perhaps turn the attention of European scientists to the work of Americans more than any other one thing that the latter have recently done. Of these advances, however, there is none so fundamental as the successful cultivation in artificial media of pathogenic protozoa, first accomplished by Novy and McNeal of Ann Arbor. The greatest difficulty in the way of studying protozoan diseases has always been the impossibility of securing the organisms by themselves, free from other living cells, and in pure culture, so that they can be studied during the course of their growth and development, and particularly so that their ability to produce disease when freed from any other possible contamination can be demonstrated. Beginning with the common trypanosoma of rats, *Trypanosoma lewisi*, pure cultures were obtained that now have been carried through sixty-seven generations. Later cultures were obtained of the organisms found in nagana, the tsetse-fly disease of Zululand, and other observers have found the method successful for the cultivation of the trypanosome of mal de caderas, a disease of South America that affects horses. Novy and McNeal report in this number of The Journal the cultivation of still another organism, *Trypanosoma evansi*, the cause of the disease surra in the cattle of the Philippines. Therefore, four distinct organisms have now been isolated in cultures, but all are trypanosomes. It yet remains, with the knowledge gained from studies of these organisms, to isolate other protozoa in a similar way. One of the chief advantages obtained by cultural methods in the study of bacteria is the possibility of determining whether two diseases with certain similarities are the same or different, e. g., typhoid and paratyphoid. The cultivation of protozoa has progressed enough to permit of similar information being obtained concerning the protozoan diseases in certain instances. For example, there has been some contention as to whether surra is the same as nagana, and perhaps the same also as other of the horse and cattle diseases produced by trypanosomes. In this paper Novy and McNeal have succeeded in showing that the trypanosome of surra is distinctly different in its cultural characteristics from the trypanosome of nagana. The future development of cultivation of protozoa will be watched with most intense interest in view of our increasing acquaintance with tropical diseases, in which they are particularly concerned, not to mention their possible connection with other and more familiar diseases.

THE MEDICAL SAMPLE BUSINESS.

A writer in the *British Medical Journal* has made a study of the advertising methods of medicine manufacturers, using for the purpose the collection of samples received by a London surgeon. The total number of packages, mostly postal, weighed fifty-seven and one-half pounds, which did not include the bulky ones, such as mineral waters, etc. The postage on these amounted to 19 shillings and 8 pence, or about $4.75. One hundred and sixty-two of the packages were of British origin. The United States comes next with fifty, while France and Germany sent almost equal numbers, thirty-four and thirty-five, respectively. In many cases advertisements were accompanied with offers to send samples, which were not accepted. Those received ranged from a stout case containing four stone bottles of mineral water a little box of tablets. Soap, ointments, tinctures, purgatives and analgesics formed the greater part. Lime juice and whiskey must not be forgotten, however, and "last but not least the babies' feeding bottle, which an enterprising firm, anxious for the future of the race, presented." Four diaries were received, one of which, weighing nine ounces, is mentioned as a customary present to the medical profession. Writing pads seem to be the form of advertising most favored by venders of drinkables. Five lists of medical and surgical appliances were received, one weighing eleven pounds, and containing the price, if not the picture, of nearly every possible surgical tool. From the continental health resorts neat little booklets were received, sometimes with a free pass to the local casino. Hot-air baths and kindred cures sent various booklets. "The medical newspapers received were not many. They were of two kinds—genuine medical journals and so-called journals which exist only for the purpose of pushing the sale of certain nostrums. The United States is the usual habitat of this last kind of parasite." Some of the American drug papers are notable for the letters they receive from numerous practitioners, and which they publish with the writers' names. The author of the article referred to says: "If these are genuine, it would appear that the standard of general education of medical men is even lower in the United States than in the United Kingdom." Many of the testimonials, however, are of British origin. The more legitimate inference we should draw from these facts would be that the class of practitioners who sign these testimonials in America are less well educated than are those that are guilty of the same folly in Great Britain. The writer has one or two more little flings at the United States which, considering the fact that these advertisers find such a comfortable field in Great Britain, are a little superfluous.

Medical News.

DISTRICT OF COLUMBIA.

Soldiers' Home Quarantined.—The Soldiers' and Sailors' Home, a private institution containing 34 soldiers and sailors has been placed in quarantine by the health officer, on account of a case of smallpox which developed in the institution.

Health of the District.—The report of the health officer for the past week shows the total number of deaths to have been 131, 72 white and 59 colored; the number of births reported was 100, 57 white and 43 colored. At the close of the week there were under treatment 8 cases of diphtheria, 25 of scarlet fever, 53 of typhoid fever, and 5 of smallpox. Among the chief causes of death were consumption, 16; heart disease, 16; kidney diseases, 13; apoplexy, 9; pneumonia, 8, and meningitis, 7.

Fraud Order Issued.—The post office department has issued a fraud order against a medical remedy company, depriving it of the use of the mails. The concern had been publishing advertisements of a medical cure-all. The assistant attorney general of the department, in the course of investigation, had the alleged remedies analyzed by the Department of Agriculture. The analysis showed the medicines or mixtures did not possess qualities or contain ingredients that could be relied on to cure any of the ailments named in the advertisements.

ILLINOIS.

Chicago.

Deaths of the Week.—During the week ended May 21, 483 deaths occurred, equivalent to an annual death rate of 13.04. Pneumonia again heads the list with 82 deaths, followed by consumption with 62, violence with 39, heart diseases with 36 and Bright's disease with 28.

New Jewish Hospital Building.—More than $400,000 has been raised by the committee for the erection of a new Michael Reese Hospital and a building committee has been appointed, with power to act.

Operation on Dr. Newman.—Dr. Henry Parker Newman was operated on for appendicitis, May 21, and the appendix removed. Dr. Newman bore the operation well, and is progressing favorably toward recovery.

Polyclinic Hospital to Expand.—The directors of the Chicago Polyclinic plan to erect a new hospital on the site purchased two years ago at Oak and La Salle Avenue, to cost $150,000, and to accommodate 150 patients.

P. and S. Commencement.—On May 24, a class of 219 was graduated from the College of Physicians and Surgeons, the medical department of the University of Illinois. Prof. Thomas J. Burrill, vice-president of the university, conferred the degrees, and Rev. A. R. Lambert delivered the doctorate address.

Sane Celebration Surgical Staff.—The promoters of the "Sane celebration" of the Fourth of July have organized a committee for the special care of children and others who may, notwithstanding the harmlessness of the celebrating agents, be injured. On this committee are: Drs. John B. Murphy, H. Gideon Wells, Wladyslaw A. Kuflewski, J. Frank Hubert, John E. Gilman, and Arthur R. Reynolds.

Pneumonia Decreasing.—Only 82 deaths from pneumonia were reported last week, or nearly 17 per cent. of the total mortality. The health department bulletin gives the following comparative figures for New York and Chicago, giving total deaths, and deaths from pneumonia and tuberculosis:

	New York.	Chicago
Total deaths, all causes	45,402	16,343
From consumption	5,065	1,758
From pneumonia	9,648	3,648
Proportion per cent. of all deaths—		
From consumption	11.15	10.75
From pneumonia	21.25	22.32

May Favorable for Children.—In its weekly report the department of health notes that this season is the most favorable in the history of the city as regards the health and life of the young. The report continues:

> Since the first of the month there have been recorded 1,553 deaths at all ages, of which number 339 were of children under 5 years of age—a proportion of 21.8 per cent. of the total. During the corresponding period last year there were 1,922 deaths at all ages, including 510 under 5—a proportion of 26.5 per cent. of the total. These figures show a decrease of 17.7 per cent. in the death rate of the under 5-year age group this year from that of 1903—which was about the normal.
>
> The cause of this most gratifying condition has been heretofore referred to, namely, the phenomenal infrequency of the contagious diseases. At the close of the week a total of 599 deaths from the diseases most seriously affecting child life had been reported since the first of the year. For the same period of 1903 there were 1,169 such deaths reported—an excess of 570, or 95 per cent.
>
> Among the most striking decreases are the deaths from diphtheria, measles, scarlet fever and whooping cough—from diphtheria this year 156, last year 300; from measles this year 9, last year 190; from scarlet fever this year 91, last year 167; from whooping cough this year 8, last year 186.

IOWA.

Indorses Pure Food Bill.—The newly organized Allen County Medical Society at its initial meeting adopted a resolution indorsing the pure food bill.

Sioux City Graduates.—At the commencement exercises of Sioux City College of Medicine, May 4, a class of twelve were given diplomas by Dr. George W. Beggs, president of the board of trustees. The doctorate address on "The Principles of Psychic Remedy," was delivered by Rev. R. P. Smith.

His Second Offense.—An eclectic practitioner of Muscatine, who either did not recognize smallpox, or willfully violated the quarantine law, has been summoned to appear before the State Board of Health and show cause why his certificate to practice in Iowa should not be revoked on the ground of incompetency. About two years ago he was summoned on a similar charge, and at that time he pledged himself to observe quarantine regulations.

Personal.—Dr. Henry L. Bawden has been elected city physician of Davenport, vice Dr. Bernhard H. Schmidt.——Dr. Edward T. Lawler was re-elected city physician of Cedar Rapids, May 2.——Dr. Bernard Michel, Dubuque, was reappointed city health officer, May 2.——Dr. Grant J. Ross has succeeded Dr. Jay M. Kilbourne as city physician of Sioux City.——Dr. James E. Miller, Des Moines, has been elected city physician, vice Dr. Newton M. Smith.——Dr. and Mrs. Fred W. Marotz, Sergeant Bluffs, have gone to Honolulu.

KENTUCKY.

Senior Student Dies.—C. V. Smith, who was within one month of graduating from the Louisville Medical College, died from typhoid fever at his home in Calhoun, May 12, aged 28.

Personal.—Dr. Fred D. Cartwright has been re-elected city health officer and secretary of the Bowling Green Board of Health.——Dr. Charles W. White, Covington, has been re-elected city health officer.

Typhoid Fever.—Dr. J. N. McCormack, secretary of the State Board of Health, reports 13,305 cases of typhoid fever in the state during the fiscal year, with 1,579 deaths, involving a money loss estimated at $963,759.

Health Board also Examining Body.—Under the provisions of the new medical law which goes into effect June 15, all physicians who wish to practice in the state will be obliged to undergo an examination conducted by the State Board of Health.

MARYLAND.

Personal.—Dr. William G. Coppage, Church Hill, has been appointed health officer for Queen Anne County.——Dr. Edward R. Trippe, Easton, has been reappointed health officer of Talbot County.

County Society Election.—The Baltimore County Medical Society elected the following officers, May 19, at Towson: President, Dr. George H. Hocking, Govanstown; vice-president, Dr. Harry S. Jarrett, Towson; recording secretary, Dr. Richard C. Massenberg, Towson; corresponding secretary, Dr. H. Louis Naylor, Pikesville, and treasurer, Dr. Benjamin Whitely, Catonsville. The new constitution was adopted.

Baltimore.

Deaths.—For the week ended May 21, the deaths were only 185, of which the death rate for whites was 13.43 per 1,000, of colored, 34.67, or general 16.72 per 1,000. Consumption caused 43 deaths. Eight cases of smallpox were reported. Of the 217 deaths for the week ended May 14 15 were from cancer.

Commencements.—The College of Physicians and Surgeons graduated a class of 82 on May 19. Four gold medals were given, as follows, to Drs. James Osterman, Utah; Morris D. Cohen, N. Y.; D. C. Mack, Pennsylvania, and R. Garn Clark, Utah.——The commencement of the Woman's Medical College took place May 27. There were two graduates, and Edwin H. Griffin, D.D., LL.D., of Johns Hopkins University, delivered the address.

New Hospital Staffs.—The new staff of the City Hospital are: Resident physicians, Dr. A. C. Biddle; associate resident, Dr. A. W. Deal; associate resident surgeon, Dr. C. G. Leslie; assistant gynecologist, Dr. J. Plumer Cole; resident pathologist, Dr. Samuel T. Darling, and assistant resident physicians, Drs. M. D. Cohen, H. K. Fleckenstein, George R. Barnes, J. H. Hartman, Jos. A. Trainor, and James Osterman.——At Bayview Asylum: Resident physician, Dr. Page; assistants, Dr. E. E. Bell, Jr., and F. B. Hines.——At Maternité Hospital: Dr. James McGinty.

NEW JERSEY.

Eminent Chemist Critically Ill.—Dr. Thomas B. Stillman, professor of chemistry at Stevens Institute, Hoboken, is dangerously ill with pneumonia.

Election.—At the annual meeting of the Burlington County Medical Society the following officers were elected: President, Dr. J. Howard Pugh, Burlington; vice-president, Dr. J. Boone Winterstein, Moorestown; secretary, Dr. George T. Tracy, Palmyra, and treasurer, Dr. Enoch Hollingshead, Pemberton.

Personal.—Drs. Maxson, Jersey City, and Norich, Lenoxville, have been appointed resident physicians at Mercer Hospital, Trenton.——Dr. John W. Bennett has been elected president of the Long Branch Board of Health.——Dr. Gordon K. Dickinson has been elected president of the Jersey City Board.——Dr. George F. Wilbur has been appointed a member of the Asbury Park Board of Health.

Examinations for Sanitary and Health Officers.—The Board of Health of the State of New Jersey announces that applicants for license to serve as sanitary inspector or health officer will be held at Trenton on the first Wednesday in June and in December. The subjects for examination will include the health laws of the state, preventable diseases, isolation and quarantine, disinfection, nuisances, collection and disposal of refuse, vital statistics, etc.

NEW YORK.

Physician's House Burned.—The residence of Dr. George D. Johnson, Oxford, was burned to the ground, May 16. The loss is partially covered by insurance.

Aftermath of Epidemic.—The common council of Watertown has appropriated $4,500 to be used by the board of health to pay expenses incurred during the recent epidemic of typhoid fever.

Reception Hospital for the Insane.—The Foley bill which provided for the establishment of a reception hospital for the insane on Manhattan Island, although opposed by Governor Odell on the ground that it was not wise to expend the $1,200,000 that was called for in the bill in making this improvement until the efficiency of such an institution had been demonstrated on less extravagant lines, was passed over the governor's veto. This hospital is actually a necessity, as in the past acutely insane patients have been kept in station houses for several days or in Bellevue Hospital until they could be transferred to state hospitals.

New York City.

Crippled Children Benefit.—The benefit for the proposed home for destitute and crippled children was a success, and increased the fund by $4,000.

Birthday Gift.—D. J. Crimmins, to mark his sixtieth birthday sent a check to St. John's Guild to defray the cost of the floating hospital this summer.

Examination.—A competitive civil service examination for the position of director of the pathological laboratories at Bellevue will be held June 7. The salary is $5,000, and it is understood that the director will be expected to give his entire time to the work.

Mosquito War.—The Health Commissioner, Dr. Darlington, has inspected the swamps of Staten Island, Northern Manhattan and the Bronx, and has taken steps to have the infested swamps filled in or drained. Crude petroleum is used in addition to drainage.

Conditional Gifts Secured.—By the donation of $40,000 by Edward R. Thomas to the Manhattan Eye, Ear and Throat Hospital, in memory of his father, General Samuel Thomas, conditional gifts of $125,000 are secured, and a new building is assured for the institution.

Meningitis on Increase.—The epidemic of cerebro-spinal meningitis has increased to an alarming extent. The department of health, in trying to fight the disease, has offered to place at the disposal of all hospitals and medical practitioners the services of its laboratories to aid in the diagnosis of the disease.

Personal.—Dr. Warren S. Bickham has been appointed instructor in surgery at the Post-Graduate College and Hospital. ——Dr. William K. Simpson has been appointed consulting otologist at the Presbyterian Hospital.——Dr. Leon L. Walters, assistant chemist of the Department of Public Charities, has resigned on account of ill health.

Hospital Cornerstone Laid.—The cornerstone of the new Woman's Hospital in West 110th Street, has been laid. The cornerstone of the old building at 49th Street and Park Avenue was used. The new structure will be six stories high, of steel and brick, with a frontage of 200 feet. When completed the cost will be more than $1,000,000.

Contagious Diseases.—There were reported to the Sanitary Bureau for the week ended May 14, 1904, 1,516 cases of measles, with 45 deaths; 389 cases of diphtheria, with 51 deaths; 363 cases of scarlet fever; 2 cases of smallpox; 113 cases of varicella; 426 cases of tuberculosis, and 172 deaths; 28 cases of typhoid fever, with 10 deaths; 97 deaths from cerebrospinal meningitis, and 242 deaths from pneumonia.

New Tuberculosis Clinic.—Since the opening of this clinic, March 1, until May 15, there were examined 794 patients; of this number 164 were found to be non-tuberculous. Bacterial examinations alone were not relied on in making diagnoses. As bearing on the social aspect in tuberculosis it was interesting to note that 55 patients out of the 68 who gave wrong addresses, were a menace to their families, friends and neighbors.

Unofficial Health Board News.—A notice has been posted in the health department building and in all the local health offices that, in the future, no information relative to the work of the department shall be given to the public, or to representatives of newspapers without the personal sanction of the health board. The commissioner has done this in order that information given out may be absolutely reliable. He said there would be no withholding of news.

PENNSYLVANIA.

Western Pennsylvania Commencement.—On May 27, a class of 51 was graduated from the Western Pennsylvania Medical College, Pittsburg.

Bequests.—By the will of Allen Flitcraft, of Media, the Chester Hospital will receive $1,000; the Friends Home, West Chester, $1,000, and the Friends Home, Woodstown, N. J., $1,000.

Marine-Hospital Transferred.—The secretary of war has formally transferred title to the old arsenal property at Pittsburg to the Treasury department for the purpose of constructing a marine hospital. This was provided for at the last congressional session, when $150,000 was appropriated for this purpose.

Autopsies for Fifteen Dollars.—The Board of County Commissioners, of Chester County, have issued an order directing that the regulation price of $15 be strictly observed as the cost for performing autopsies. The operating physicians formerly set their own prices, ranging from $30 to $40. The sum now stipulated by the commissioners specifies that $15 will be paid in all cases for internal examination, and $5 only for external examination.

Pennsylvania a Non-Registration State.—The eleventh annual meeting of the Associated Health Authorities and Sanitarians of Pennsylvania was held in Gettysburg, May 26 and 27. Dr. Cressy L. Wilbur, statistician of the United States Bureau, delivered an address on: "How Can Pennsylvania Secure Effective Registration of Mortality Statistics." Dr. Benjamin Lee, secretary of the State Board of Health, stated that Pennsylvania is one of the few old commonwealths in this country which is classed as a non-registration state.

Prevention of Tuberculosis.—At the recent annual meeting of the Pennsylvania Society for the Prevention of Tuberculosis, the following officers were elected: President, Dr. Howard S. Anders, Philadelphia; vice-presidents, Drs. J. Solis Cohen, Philadelphia; Guy Hinsdale, Hot Springs, Va.; Benjamin Lee, Philadelphia; S. Adolph Knopf, New York City; Albert E. Roussel, Philadelphia; Lawrence F. Flick, Philadelphia; Samuel G. Dixon, William Moss, Philadelphia and Mazyck P. Ravenel, Philadelphia, and Messrs. Talcott Williams and Samuel Cartner; solicitor, James L. Stanton, Esq.; treasurer, the Commonwealth Title and Trust Company; secretary, Dr. Ward Brinton, Philadelphia, and directors, Drs. J. Solis Cohen, Lewis F. Flick, Guy Hinsdale, Howard S. Anders, Mazyck P. Ravenel, Albert E. Roussel, Leonard Pearson, Joseph Walsh, Samuel Scoville, Ward Brinton, George W. Norris, and Daniel J. McCarthy. The society voted that short articles on subjects pertaining to tuberculosis and its prevention be sent weekly to the lay press. A course of lectures on the same subject for the education of the people has also been planned.

Philadelphia.

Hospital Appointments.—The following have been elected resident physicians to the Polyclinic Hospital: Drs. James K. Hall, John D. Butzner, Edward D. Lovejoy, George E. Adams, and John Read.

Tablet to Dr. Stackhouse.—A tablet erected in memory of Dr. Susan Palmer Stackhouse by the alumni of the Women's Medical College, was unveiled May 19. Dr. Stackhouse was a member of the class of 1873, who died in 1888 and bequeathed a large sum of money for the establishment of a gymnasium in the college.

Personal.—Dr. Edward A. Mallon, who was operated on for appendicitis in Vienna, is rapidly improving. He has been in Vienna since October.——Dr. F. Savary Pearce, professor of neurology in the Medico-Chirurgical College, who has been ill for some time, is spending a recess with his parents in Steubenville, Ohio.

Women Graduate.—The commencement exercises of the Women's Medical College was held May 18, when 43 young women received degrees from Mrs. Mary E. Mumford, president of the board of corporation. Prof. Robert Ellis Thompson, S. T. D., president of the Central High School, delivered the address to the graduates.

New Medical Laboratories.—The new medical laboratories of the University, which have been under construction for four years, will be dedicated June 10. The buildings will cost, exclusive of the ground and equipment, about $700,000. Formal addresses will be made in the Laboratory of Pathological Histology by Prof. H. P. Bowditch, Harvard; Prof. R. H. Chittenden, Yale; Prof. George Dock, University of Michigan, and Prof. Horatio C. Wood, University of Pennsylvania.

Health Report.—All contagious diseases show a marked decrease this week, as compared with last week, the figures for typhoid fever, smallpox, scarlet fever and diphtheria being much less than for any similar period in several months. There were only 182 cases of typhoid fever reported, and 11 cases of smallpox. The death rate shows a marked decrease. There were 477 deaths recorded during the week, a decrease of 43 from those of last week, and an increase of 6 over the corresponding period of last year.

New Hospitals.—Plans are on foot for the erection of a new Rush Hospital at a cost of $100,000. This is to replace the present building. Fifty patients are at present under treatment in the institution, and more room is imperatively needed. ——Application is to be made on June 13 for a charter for a new hospital in Frankford, to be known as "The People's Hospital." A legacy of $20,000 has been left for the establishment of the hospital. An additional $3,000 has been collected by the ladies' auxiliary.

Bequests.—By the will of Maxwell Sommerville, the University Hospital received $10,000 for the endowment of a room. The same testator devises $1,000 to the Philadelphia Home for Incurables; $1,000 to the Home for Crippled Children, and $1,000 to the Home for the Training in Speech of Deaf Children.——In the adjudication of the estate of Leopold Bamberger, awards to charity were made as follows: Jewish Hospital, $5,000; Jewish Foster Home, $2,500; Orphans' Asylum, $1,000, and Society for the Prevention of Cruelty to Children, $1,000.

Faculty Reorganization.—A plan for the reorganization of the faculty of the Department of Medicine in the University of Pennsylvania has been approved by the Board of trustees, whereby the faculty membership has been extended to the clinical associated and assistant professors, to the associates and lecturers, and to a limited representation from the subordinate staff. The scheme provides for an executive body or council, to be composed of the heads of departments in fundamental subjects and two representatives of the specialties. The plan will be put into effect September 1.——Jefferson Medical College has adopted a similar plan, electing all the clinical professors to a full professorship. The first to be thus honored are Drs. Orville Horwitz, W. Joseph Hearn, H. Augustin Wilson and D. Braden Kyle.

GENERAL.

American Association of Life Insurance Examining Surgeons.—The annual meeting of this association will convene on the Steel Pier in Atlantic City, Monday, June 6. The morning session will begin at 10:30. There will be an afternoon session on the pier and an evening session at the Hotel Islesworth. The officers invite the members of the American Medical Association and others interested.

National Association for the Study and Prevention of Tuberculosis.—A meeting of those interested in the formation of this body is to be held in Atlantic City June 6, at 8 o'clock, in the public school building. The committee appointed for the purpose in Philadelphia March 28 has prepared a constitution and by-laws, which will be under consideration. The secretary of the association is Dr. Henry Barton Jacobs, 11 Mt. Vernon Place, West, Baltimore.

Reciprocity Convention.—The third annual meeting of the American Confederation of Reciprocating Examining and Licensing Medical Boards was held in Chicago, May 24. The examining or licensing boards of the states of Illinois, Indiana, Wisconsin, Michigan, Iowa, Nebraska, Kentucky and Maryland were represented. The address of the president, Dr. W. A. Spurgeon, Muncie, Ind., of the Indiana State Board of Medical Examination and Registration, dwelt on the insufficiency of the courses in the colleges and the lack of proper relation between the various branches. He advocated regulation of the medical college curricula and of state board questions as a basis for reciprocity and uniformity. A more detailed report will be given next week.

FOREIGN.

Yellow Fever in Mexico.—A case of yellow fever is reported in Valles, one in Tampico and one in Vera Cruz.

Plague in Formosa.—The island of Formosa has been subject to plague for five years, but during the month of March the mortality was unusually high; 558 cases are reported, with 369 deaths.

Medical Inspectors of Schools in Germany.—The city of Duisburg, with 110,000 inhabitants, has appointed 10 medical inspectors for its schools. Berlin has 36 inspectors to a population of about 1,980,000.

The Berlin Vacation Medical Courses.—The next course will commence September 26 and last until October 22, 1904. The course is in charge of the docents' union. Further particulars may be obtained from Dr. Melzer, Ziegelstrasse, 10-11, Berlin.

Poor Milk in England.—At the annual meeting of the Sanitary Inspectors' Association, Sir James Crichton-Browne declared that London has a very poor milk supply, and urged that the method and quality of the milk supply of London should be taken up by those responsible and greatly improved.

A new journal for research in physiology has been founded in France with the title *Archives Internationales de Physiologie.* The proprietors and editors are L. Frédéricq of Liége and P. Heger of Brussels, with a long list of collaborators which includes Kronecker, Pawlow, Dastre and J. N. Langley of Cambridge.

German Medicine in Japan.—Profs. E. Bälz and J. Scriba have been officially connected for several years with the Japanese medical school at Tokio. All the preparatory and medical courses are given in German. The present and former pupils of these two professors have had bronze busts made of them, which are to be installed in front of the new medical school building.

No Postage Charge for Serum Literature.—The official institute at Vienna, which is producing antidiphtheria antitoxin and the scarlet-fever serum, does not have to pay postage on communications connected therewith. Reports from physicians throughout the country in regard to the results obtained with the serum are also transmitted to the institute free of charge in the mails.

Plague in Peru.—The bubonic plague epidemic in Lima and Callao, Peru, appears to be under control. Thorough sanitary inspection has been carried out and many changes made in sanitary provisions. Cities are not built properly, and most of the cases of plague occur in closely settled tenements. The sewerage system is very deficient. All cases of plague have been removed to the lazaretto outside the city.

Morbidity of Physicians in Austria.—Some recently published statistics show that only 7 per cent. of the mortality among physicians in Vienna is due to tuberculosis. This is less than half the general average throughout the country. On the other hand, nearly 40 per cent. of the deaths are due to heart and kidney affections. It is also stated that 40 per cent. of all known morphin habitués are physicians.

Payment of Physician's Services.—The Berlin physicians are considering the adoption of a rule that all accounts for services rendered must be presented at once after the close of the treatment, and at most not later than three months afterward. Certificates and testimonials to private parties must be paid for on the spot, and also night visits or consultations on behalf of persons with whom the physician is not acquainted.

German Physicians Not Allowed to Send Student Substitutes.—The German authorities have issued an ordinance denouncing the practice of sending a medical student as the physician's representative. This practice they say not only shows a lack of consideration of the patient, but has a directly injurious effect on the standing and prestige of the profession. A physician so doing lays himself open to proceedings in a court of honor.

Anti-Alcohol Medical Congresses.—The Sixth Northern Anti-Alcohol Congress will be held at Copenhagen July 6 to 12, 1904. The eighth German congress of the same kind will be held at Cassel in September. The committee in charge has offered a prize of $75 for the best work on the action of alcohol on the warm-blooded heart. Competing articles should be sent before August 1 to Prof. Hans Meyer of Marburg, Rosemann of Bonn, or N. G. Keferstein of Lüneberg, with the name in a sealed envelope.

Naunyn's Resignation.—Naunyn retires this summer from further service as professor of pathologic anatomy, etc., and chief of the medical clinic at Strasburg. He is now in his 66th year. He was one of the founders of the *Archiv. f. exp. Pathologie und Pharmakologie* in 1872, and in 1896, with Mikulicz, founded the *Mitteilungen a. den Grenzgebieten* (Communications from the Borderland Between Medicine and Surgery). His most important published works have been on cholelithiasis and diabetes.

German Congress for Experimental Psychology.—The first congress of this kind convened recently at Giessen, April 18 to 22 with a comparatively large attendance of psychologists, psychiatrists, neurologists and teachers. The most important result of the congress was the founding of a society for experimental psychology with E. Müller of Göttingen for president.

and Schumann of Berlin secretary. The society will publish its communications in the *Archiv. f. die ges. Psychologie* and the *Archiv f. Psych. und Physiologie*. One of the chief aims of the society is to organize collective research on the various aspects of experimental psychology and its "borderlands."

Resolutions Adopted by the Second Latin-American Medical Congress.—Before adjourning, April 10, the congress voted to send a message of congratulation to Dr. O. Cruz, chief of the board of health at Rio Janeiro, for his successful campaign against yellow fever. Another message of congratulation was also voted Drs. Carroll and Agramonte for their work on yellow fever in collaboration with the late Dr. Reed. Resolutions were also adopted urging the appointment of a committee to study the medical geography of the different states, also the flora of the different countries for medicinal use, to report at the next congress, which will be held at Montevideo in two or three years. The creation of training schools for nurses and of veterinary schools was also urged. Three resolutions were devoted to penology, one asking that the execution of the penalty should be suspended in case of insanity or intercurrent disease until the criminal has recovered during detention in some hospital or other safe place. The period of insanity or other affection shall be computable to the duration of the sentence. A further resolution also urged the establishment of small prisons at various points rather than a large central prison. By this means the convicts would remain in their home climate, under influences to which their health is accustomed. The formation of some Latin-American center for the study of tropical diseases was the last resolution adopted. See page 1440.

LONDON LETTER.

Physical Education in Elementary Schools.

In 1903 the government appointed a committee to examine the course of exercises in use in schools with a view to its improvement. A report has just been issued condemning the course exercises as not constructed on well defined principles. Much of it consisted of military drill, which the committee has now replaced by exercises which are intended to build up the physique. They number 109, and are divided into sets, the two preliminary being class arrangements (drill) and elementary starting positions; then follow arm flexions and extensions, balance exercises, shoulder exercises, head and trunk exercises, marching, jumping and breathing exercises. Although two or three set lessons a week are recommended stress is laid on the practice of some of the exercises for a few minutes during each school lesson. Exercises for all parts of the body are provided. The deformities prevalent among children which are liable to be intensified by school life are specially provided for by exercises to correct faulty posture. Such as raising the heels to correct the tendency to flatfoot and bending the head and the trunk backward to counteract the effects of the stooping posture often acquired by working at desks. Great stress is laid on correct breathing. While no fixed course of physical training for infants is recommended, breathing exercises from the earliest period of school life are insisted on, the formation of habits of correct nasal breathing being regarded as of great importance.

The Nomenclature of Death Certification.

With the advance of knowledge there is a constantly changing classification of disease with which the registrar-general makes praiseworthy attempts from time to time to grapple. He has just distributed copies of a new list of diseases causing death, and in the accompanying notes he expresses the hope that in future medical practitioners will assist the work of registration and compilation of statistics by abandoning as far as possible such obsolete terms as convulsions, scrofula, and phlegmon, which are given in the list, to say nothing of such vague words as consumption or decline, which are only popular terms. In certifying death from smallpox the physician is asked to state carefully the patient's condition with respect to vaccination. Puerperal fever is to be described as pyemia, septicemia, or septic intoxication of puerperal origin. Three forms of pneumonia are recognized and are included under general diseases. The epidemic form of cerebrospinal meningitis is to be distinguished as cerebrospinal fever. The exciting cause of peritonitis is to be given. The medical officers of asylums, in certifying the cause of death of lunatics are asked to state particulars of the brain disease for which the patient was under treatment, in addition to the disease which caused death. The obvious criticism of many of these suggestions is that they are "counsels of perfection." In the absence of a necropsy, which is seldom possible in private practice, the answer to many of these questions is impossible.

A Traveling Ophthalmic Hospital in Egypt.

At the beginning of 1903 Sir Ernest Cassel, the well known philanthropist placed at the disposal of the Egyptian government $200,000, to be used for the benefit of sufferers from diseases of the eye, which are so prevalent in Egypt. One of the objects was to train native physicians in the treatment of these diseases, according to modern methods. The Egyptian Sanitary Department decided to establish a traveling ophthalmic hospital so that patients would not have to make long journeys to obtain treatment. Mr. A. F. McCall, who has held various offices at the London Ophthalmic Hospital, was appointed to organize and direct the enterprise. The hospital was recently near the town of Menouf in the west of the Nile Delta. It consisted of eight Indian tents and kitchen of sun-dried bricks. The largest tent was used for operations of which on an average six were performed daily, about five-sixths of the total were for entropium (trichiasis). There were two tents for the accommodation of in-patients, only the most severe cases, especially those requiring intraocular treatment operations, being admitted. In another tent out-patients were treated by Mr. MacCallan's Arab assistant, who was trained in Cairo. Including this assistant the staff of nurses and servants consisted of 10 persons. The hospital had gained the confidence of the natives, who came in large numbers.

Radioactivity of Brine Baths.

It is often stated that natural mineral waters have properties which do not exist in mixtures produced by combining their various constituents. Some explanation of this hitherto unexplained fact is furnished by researches made in connection with the celebrated Droitwich baths of Worcestershire. These are brine baths, and the most saline in the country. Mr. F. Soddy of University College, London, has found that the gas given off by water is distinctly radioactive. Possibly radioactivity is an important factor in balneo-therapeutics, and is the cause of benefit being derived from one spa when it is not from another apparently equally suitable.

King Edward VIIth's Hospital.

An institution which will prove most valuable to the officers of both services, when suffering from serious disease or requiring the performance of an important operation, has been opened in London. It owes its existence to the benevolence of Miss Agnes de Keyser, whose services to the officers invalided from South Africa are well known. A private nursing home for officers in London was urgently required. This one will form a sort of London branch to Osborne House in the Isle of Wight (recently presented for the purpose by the king, and formerly a royal palace). Miss de Keyser, who is believed to be a large contributor to the expenses, will manage the hospital.

Endowment of a Lectureship at the Royal College of Physicians.

Dr. George Oliver, a fellow of the Royal College of Physicians, has presented to the college the sum of $10,000 in trust for the endowment of a lectureship or prize to be called the Oliver-Sharpey Lectureship or Prize, in memory of the late William Sharpey, F.R.S., professor of physiology in University College, London. His purpose is to encourage the application of physiologic knowledge to the prevention and cure of disease and the prolongation of life. One or two lectures will be delivered annually at the college or a prize awarded for work done.

The Weber-Parkes Prize.

Drs. T. H. Green, E. Seaton, and Wethered have been appointed adjudicators of the Weber-Parkes prize and medals for 1906, and have selected as the subject of the essay for that occasion: "The degree of infectivity of pulmonary tuberculosis and the administrative measures desirable for the control and treatment of the disease." This prize, of the value of $750, and a silver medal, is awarded triennially to the writer of the best essay on some subject connected with the etiology, prevention, pathology, or treatment of tuberculosis, especially with reference to pulmonary consumption in man. It is open to members of the medical profession in all countries.

Plague in South Africa.

From April 23 to May 2, 14 fresh cases of plague were notified in the Transvaal, 11 in colored persons and 3 in white. The total number of cases now numbers 142,123 in colored persons, and 19 in white. Since April 23 5 deaths have been reported, all in colored persons. For the week ending May 7, 11 fresh cases were reported, 5 in colored and 6 in white persons, and 4 deaths, 1 of a white and 3 of colored persons. In Cape Colony for the week ending April 16 only one case of plague was reported, namely, a colored man at Port Elizabeth. Plague infected rodents were also found in the town.

Metropolitan Street Ambulance Association.

The very defective ambulance service of London has led to the formation of this association by the physicians of the metropolis, with the object of improving the situation. About 1,000 have joined the association. At the last meeting it was resolved to urge the need of an organization under one body of an improved ambulance service, summonable by telephone and provided with more rapid transit. As a result a very influential deputation consisting of the president of the association, Mr. Reginald Harrison, and many of the leading physicians and surgeons of London waited on the London County Council. It was suggested to combine the ambulance service with the fire brigade and by adding to the latter sufficient men and horses to provide for the 15,000 casualties which yearly require removal to hospital.

PARIS LETTER.

The Recent Epidemic of Typhoid Fever in Paris.

During the month of March there has been an epidemic of typhoid fever in Paris. The cases were seen more specially in certain parts of the capital, the 16th, 17th and 18th arrondissements, and also parts of the 13th and 14th. The source of infection seems to have been a case of typhoid fever, which took place on the borders of Normandy, in the watershed which furnishes water to the Avre, a small river, which is a source of supply for the capital. This case was only discovered by the medical inspector of the region after two weeks' duration, and the dejecta, which had been thrown on a dung heap, had not been sterilized. Two or three weeks after cases of typhoid fever began to appear in Paris, and instead of the average of 40 or 50 cases a week with a few deaths, the official statistics showed as many as 150 or 170 cases. There were 22 cases in one street, 2 deaths taking place the same day. There was a good deal of commotion, and the *Matin*, a daily paper of the yellow type, made a good deal of capital out of it, printing editorials in which the chief of the hygiene bureau, Dr. Monod, Bechmann and Martin, the heads of the water-supply department, were most virulently attacked. The epidemic was of short duration, the Avre water being cut off for a time, and the statistics are now about normal. Thanks to the publicity given to this by the *Matin* and other papers, the water used by the population was boiled. One characteristic of this epidemic was the tendency to relapses, which seemed more frequent than usual. It is well to state here that most cases of typhoid fever seen among Americans in Paris are of exotic origin, and come on after traveling through Italy or the provinces. Certain towns in Normandy and Brittany have been subject to epidemics of this nature, such as Dinard and Trouville, though at present there is no report of such a condition in such parts of France. The Paris water supply is furnished from several springs or small rivers, and twenty years ago, when the supply was not as large, it was now and then found necessary to draw on the Seine. This river was even tapped below Paris, a most detestable proceeding, and which caused so much commotion that it was found necessary to discontinue this practice. Each time that the unfiltered Seine water was put on, there was an epidemic of typhoid fever in the parts of the city where this water was used. It must be said that the number of cases of typhoid fever is steadily diminishing, and one no longer sees in the hospitals the rapidly fatal cases which were so prevalent fifteen years ago. The latter were more often found among foreigners. Swiss or German servant girls, who had recently come to Paris, and were subjected to a severe strain through nostalgia and various other causes of depression.

Cancer of the Breast Treated by Ovariotomy.

At a meeting of the Society of Surgery Dr. Guinard presented a woman 45 years old who had a cancer of the breast and a large fibroid of the uterus, which was rapidly increasing in size. Dr. Guinard removed the uterus as well as the ovaries, and shortly after the operation the glands of the axilla disappeared and the tumor of the breast diminished in size. After three months the tumor has well-nigh completely disappeared, though an examination of a small portion of the tumor shows that it is a fibrous carcinoma. It seems that music can alleviate the sufferings of women during parturition, and the *Presse Médicale* reports that Count Patrossof, director of the Public Assistance in Russia, has had an organ placed in the St. Petersburg Maternity. Whenever a woman begins to feel the first pains of childbirth, one of the nurses turns a crank, which grinds out a tune on the organ. In such conditions the birth of the child takes place without causing much pain to the assistants, the paper adds humorously.

Professor Pinard's Statistics.

It is rather interesting to note the statistics obtained in the obstetric clinic of Professor Pinard, which contains 57 beds. Since 1890, 31,539 births have taken place in this service, and out of this number 2,580 required an intervention. There were 167 deaths, which makes a mortality of 0.53 per cent. Out of these 167 cases, 71 were due to septicemia, or 0.22 per cent. In the gynecologic section 631 operations were performed, with 35 deaths. In his service of Lariboisiere from 1882 to 1889, Professor Pinard had 12,580 cases of parturition, with 94 deaths, or 0.74 per cent., and 0.39 per cent. mortality.

Marfan's Diphtheria Statistics.

Drs. Marfan and Menard have recently published the statistics of diphtheria at the Special Pavilion of the Hospital for Sick Children in Paris. From May 1, 1902, to May 1, 1903, 1,142 children were treated, and the mortality was 15.8 per cent. By suppressing all cases where death took place within the first twenty-four hours, the mortality is reduced to 11.8 per cent., and to 9.3 per cent. if all the cases within the first twenty-four hours are suppressed. Prophylactic injections were made to 1,000 brothers anad sisters of the patients, 5 c.c. being injected. Only 2 had diphtheria, one twenty-four days and the other four days after the preventive inoculation. Diphtheria has shown itself less malignant during this period, though croup has been more prevalent. Cases of measles and croup were treated by intubation, with good results. Local treatment was very much reduced, and only employed in the gangrenous forms.

DUBLIN LETTER.

State Registration of Nurses.

There is much excitement in the nursing and hospital world over the question of the state registration of nurses. We have mentioned the provisions of the bill now before parliament. Many hospital matrons and chairmen of hospitals are opposed to any state registration, since they believe that examination is not at all a fit means of judging of a nurse's qualifications. Much more important than any quantity of knowledge are those qualities, real though incalculable, of tact, temper, character, of which a state examining board can take no account. The truth seems to be that state registration is almost necessary if the profession or calling is to maintain its dignity. It will, however, have a general leveling effect, and will injure the hospitals which at present enjoy greatest prestige, while giving undue advantage to the less important training schools, for the public are not likely to distinguish carefully as to the place of education of a nurse whose qualifications have received state recognition. The Irish Nurse's Association held an important meeting in Dublin last week in support of the present bill, and many of the most influential medical men in Dublin were present and took part.

Irish Poor-Law Service.

An important contribution to the literature of the Irish poor-law grievances has just been made by Surgeon-General Evatt, C. B., a special commissioner appointed by the British Medical Association to investigate the subject and report on it. He was quite a stranger to Ireland and Irish ways of life and thought, so that his treatment of the subject comes to us with a freshness and impartiality which render his report very valuable. He spent several months in traveling through every district of Ireland, and he gives a truthful and life-like picture of the ordinary routine of Irish dispensary work. He fairly apportions blame where it is due, and he shows clearly the deleterious effect on the character of the medical officers of the conditions under which they have to work. At the same time he records in the most cordial terms his high opinion of the rank and file of the poor-law medical officers:

> I have seen their devoted services and driven with them in the storm and the r[illegible] of their splendid struggle against diseas[illegible]
>
> I have learne[illegible] y, and I can never forget their many [illegible] lid devotion to Ireland. their [illegible] views in the land of narrow views The [illegible] Ireland contains the most level headed. the [illegible] animosities, and the most just-minded men [illegible] land, and *with just treatment* they must come to the front. The struggle will be long and trying, but they must never despair, and as the years go on victory will surely come if they stand up as they do for humanity, progress and all that means betterment for the Irish people.

His statement of facts and observations is more valuable than his suggestion of the means of reform. The latter is, indeed, by no means original, and is already discredited. It is that instead of having individual medical officers under the control of local elective boards, the whole poor-law medical service should be unified into one central government system.

The difficulties in the details of arrangement are enormous; but, even leaving them out of account, the plan will never be popular. Whatever distrust medical men in Ireland may feel for local elective bodies, they are not likely to look with greater favor on a government department.

Sudden Deaths.

During the last few weeks we have lost two of the best-known Dublin surgeons with alarming suddenness—Sir Philip Smyly of the Meath Hospital and Doctor Austin Meldon of Jervis Street Hospital. In each case, while perfectly well sitting down to dinner, a stroke of apoplexy intervened, and death followed almost immediately. They lived within a few doors of each other, and it is curious to reflect that another neighbor, himself a great surgeon, Mr. Henry Croly, died with equal suddenness six months ago. Both Sir Philip Smyly and Dr. Meldon were in possession of large practices, and enjoyed the respect of their colleagues and the public. Their contributions to the literature of surgery, at any rate in recent years, were not numerous.

Correspondence.

So-Called Synthetics and Ethical Nostrums.

NEW YORK CITY, May 1, 1904.

To the Editor:—In THE JOURNAL, April 28, there appears a letter from Dr. Summers of the Organic Chemical Company, formerly the Liberty Chemical Company. The letter hardly requires an answer. Still a few remarks may help to throw some light on the entire patent nostrum controversy. Dr. Summers asks the question: If his thermol is nothing but impure acetphenetidin, how did he obtain a patent on it? Dr. Summers did not obtain a patent on thermol. He obtained a patent on acet-salicyl-phenetidin; in the patent the word thermol is not mentioned. The company tries to give the impression that thermol is acet-salicyl-phenetidin, but it will be noticed that on the thermol boxes the name acet-salicyl-phenetidin does not appear, and as a matter of fact the product for which a patent was obtaned and thermol are two different substances! I present one proof which can not be disputed, which Dr. Summers himself admitted, and which he was unable to explain. The melting point of a substance is as much its integral characteristic as any chemical test. In organic substances the melting point is frequently the most important test of identity. The substance for which a patent was obtained by Dr. Summers melts at 92 C. (at least so it is claimed in the patent, No. 706355). The substance sold as thermol melts anywhere at from 128 to 134 C. (thus by the way showing that it is not of uniform composition), while, when purified and recrystallized, it melts at 135 C., namely, the melting point of phenacetin! And as to salicylic acid, some samples show the presence of free salicylic acid, while in others it can not be demonstrated at all, neither in the free state nor in combination. That is, it can not be split up by any known chemical tests, thus showing the absence of the acid. I have four samples of thermol, and each one presents a different color, different crystalline structure and different melting point.

Now about iodomuth. If the iodin in the iodomuth is so firmly bound to the molecule that it can not be demonstrated by ordinary chemical reagents, then it is worthless therapeutically, because the action of such substances depends on the ready liberation of iodin and its action *in statu nascendi*. Take airol, for instance, which is bismuth iodosubgalate. In that product the presence of iodin can be instantly demonstrated.

In the preparation, urasol, Dr. Summers shirks the issue altogether. They claimed that it contained anacetyl radical. I showed that it did not. Did Dr. Summers try to controvert my statement? No. not at all. He only asks: What is the impurity? Here it is not merely a question of impurity. The entire claimed composition is in doubt. (I might add that in the original paper, as read at New Orleans, each product was named both by its chemical and its trade name.)

It is not necessary to reply to Dr. Summers' accusation of partisanship, though I may be compelled by circumstances to go into that matter fully. The origin of a preparation makes absolutely no difference to me. Among the preparations mentioned in my article there are several of foreign manufacture. So, for instance, dymal, montanin, remarol, horit, musol, lazon, katharol, parietin, rachitol, etc., are all of German manufacture.

My analyses are so perfect, my statements are so incontrovertible, that the only thing my detractors can do is to question my motives. But you can not fool all the people all the time, and the medical profession is slowly but gradually beginning to discern between the legitimate manufacturers of medical preparations and the fakirs.

WM. J. ROBINSON.

Medicine in Colorado—An Overcrowded Field.

PUEBLO, COL., May 16, 1904.

To the Editor:—So far as medicine is concerned, the cry of "Go west, young man," has changed in Colorado to "Go east." No state in the Union and no country in the world is so well supplied with physicians as Colorado. Hundreds of medical men have sought the mountain air of Colorado on account of their own health or the health of some one belonging to them. This has produced just one result—an overstocked market of physicians, good, bad and indifferent. Denver has a population of 133,859, but has almost 600 physicians. Colorado Springs has about one physician to every 200 of population. In Pueblo the same condition of affairs prevails, with this exception—which has lured many a young doctor to stop in Pueblo long enough to spend all his capital before he realized why practice was not coming his way. Pueblo has a population of about 60,000, but of this number 10,000 are Mexicans who mean little or nothing to physicians. Then, owing to the location of large steel plants and smelters and manufacturing industries, 28,000 more of the population are under contract physicians. The largest hospital in the city is a contract hospital belonging to the Fuel and Iron Company. Notwithstanding this, there are no less than 33 men who make a specialty of fitting glasses to the eyes.

Among the mountain towns proper the same contract medical work is the rule. This condition of affairs is not generally known until men have spent their railroad fare and gone to Colorado to find it out for themselves. Added to this is the fact that the state itself is a health resort. Apart from those who come to Colorado on account of lung trouble there is not the same amount of sickness found at lower altitude. This means that the same proportion of physicians is not required.

This letter is not meant to deter men who need to change climate from trying Colorado, but being in a position to see almost every week some physician, old or young, stranded, after an honest trial to gain a practice in Colorado, it seems that a fair statement of the existing conditions ought to be made. Young graduates are sent out every spring with eloquent commencement orations ringing in their ears that there is room at the top, but I can point to-day to a dozen men who have prepared themselves with the best training possible, men who have taken full collegiate courses before entering their medical schools, who have followed their medical course with one or two years' hospital training, and this, with another term in Europe, and yet out in Colorado are making a bare living. For themselves or families they have been obliged to make a change to mountain air. It is not uncommon to find in Colorado physicians who, back east in established practices, were making ten and twelve thousand dollars a year, come to Colorado for the health of wife or daughter, and be able to pick up only a practice of a thousand or twelve hundred a year. But this is done cheerfully for the sake of those they love. And it should be for health, not wealth, that physicians seek Colorado.

JOHN INGLIS.

The Hospital Maintenance Problem.

MUNCIE, IND., May 21, 1904.

To the Editor:—In your editorial, "The Hospital Maintenance Problem," you speak of the difficulties of caring for deficits constantly coming up, and of the fact that the remedy is not clear. It seems to me that the state of Indiana has the plan that will eventually solve the problem.

It was my good fortune to evolve the plan out of which, with the assistance of friends in the legislature, there came a law that makes ample provisions for the care of all who are on the pauper list and who must be cared for at the expense of the public. The law provides that the commissioners of the various counties may, alone or in conjunction with hospital associations, erect and maintain hospitals; that they may accept donations, organize auxiliary associations, permit lodges to furnish rooms, etc., and to donate for their care; that they may make ample provision for the care of pay patients at the usual fees; that training schools may be run in connection with the institutions; that charity patients may be sent to the institution by the township trustee, who, in the state of Indiana, is the guardian of the poor; and that the care of these shall be furnished at the actual expense of the work.

The law further provides that after all moneys, derived from all sources, including profit from pay patients, donations, etc., is expended the county commissioners shall pay the deficit from the county treasury. No one connected with a hospital as a member of any board of managers can derive any financial profit from the institution, and the entire plan is that the work shall be done in a business way as a matter of charity, and at the actual sworn expense of the same.

Copies of this law can probably be had from the Board of State Charities, as it is classed under the charity laws of the state. I believe it is destined to solve this much-discussed problem of caring for hospital expenses.

George R. Green, M.D.

The Typhoid Mortality of Savannah.

Baltimore, May 21, 1904.

To the Editor:—Will you kindly give me space to correct an error in my article on "Typhoid Fever" in The Journal, Jan. 9, 1904? In classifying more than 3,000 American cities with reference to population and typhoid mortality, I have assigned far too high a mortality to Savannah. The error arose by losing the line of figures in the census reports and taking as the mortality of Savannah the figures one step to the right of Savannah's place. The error changes the average for the 45 cities in Savannah's group nearly ten points. It does not alter the evidence that typhoid fever mortality in cities has a generally inverse ratio to population, but the mistake gives Savannah a bad eminence, which it by no means deserved. So far from deserving the distinction of the highest typhoid rate, Savannah is, in fact, conspicuous among cities of the class by reason of a low typhoid mortality.

John S. Fulton.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

POSTMORTEM ON A DEAD BODY.

Philadelphia, May 19, 1904.

To the Editor—Many thanks for calling my attention in the April 9 number of The Journal to a typographic error in my dictionary. The omission of a semicolon causes the apparent tautology. The line should read: "Autopsy. Postmortem; examination of a dead body."

W. A. Newman Dorland.

NORMAL SALT SOLUTION IN HYPODERMIC MEDICATION.

Louisville, Ky., May 16, 1904.

To the Editor—Can the various forms of hypodermic medication be given using normal salt solution for the solvent? If there are any exceptions what are they?

Henry Skeller.

Answer.—Considering that the agents used hypodermically are as a rule of *great* potency and are therefore employed in comparatively weak solutions, the amount of sodium chlorid in normal salt solution—6 per mille—would not cause any reaction except with some synthetics of rare occurrence. Solutions of some of the alkaloid sulphates may on standing show separation, which, however, would be prevented by using the respective hydrochlorids of the opium alkaloids, the tropins, quinin, strychnin, cocain, etc. In fact, the cocain solution for local anesthesia known as Schleich's is a solution of cocain hydrochlorid 0.1, morphin hydrochlorid 0.025, sodium chlorid 0.2, sterile water 100 c.c., preserved by the addition of two drops of phenol. Schleich found that injection of pure water caused pain, whereas the normal salt solution was painless, but produced no analgesia. On the other hand, a salt solution one-third the strength of the normal solution—two per mille (0.02)—produced but little pain and was slightly analgesic. Referring to the subject of "Hypodermatic Medication," in the Reference Handbook of the Medical Sciences, the following paragraph is found: "Distilled water is not essential in making the solutions; indeed, it is inferior to river, cistern or well water, either of which will answer every requirement, if only free from visible impurities." No caution is added as to the necessity for sterilization. That water may be used for hypodermic use as long as it is free from visible impurities is a statement that should not go unchallenged.

COST OF POST-GRADUATE WORK IN VIENNA.

To the Editor:—Please state: 1. The minimum expense, which includes railroad fare from Chicago, steamship fare, clinic fees, board and other necessary incidentals, of a six months' course at the Vienna clinics. 2. Can much benefit be derived by one with little or no knowledge of the German language? 3. What is the best time of the year to spend this time there? 4. Please state any other useful or necessary information or references.

Quizzical Doctor.

Answer.—1. A categorical answer is very difficult. One could get along on $400, but this might be unpleasantly economical. Better say $500. The transportation from Chicago to Vienna is about, third class, $50, and first class $100; returning, a little more. This includes railroad and steamship fare. Clinic fees are very little, but fees to instructors—private docent—may cost $15 or $20 for each three-weeks' course. Board can be had at $6 per week. 2. Yes. 3. October to March to see the most famous men and May to September for practical work under the assistants at the clinics. The latter have control of matters while the chiefs are away on their vacations. 4. Write to Dr. F. G. Harris, 8 Schlosselgasse No. 2, secretary Anglo-American Medical Association, Vienna. (See The Journal, April 16, 1904, page 1035.)

PRIVILEGED COMMUNICATION.

Bristol, N. H., May 16, 1904.

To the Editor:—In a divorce suit brought by the husband for adultery, has the court a right to compel the physician to disclose his *treatment* of the wife and for what diseases, this being done to prove the source of gonorrheal infection of the husband?

J. W. C.

Answer.—The states and territories that have passed laws extending the privilege to professional communications between physicians and patients were, in 1900, Arizona, Arkansas, California, Colorado, Idaho, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Montana, Nebraska, Nevada, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Pennsylvania, Utah, Washington, Wisconsin and Wyoming. Possibly others may have passed laws within three or four years. In the states named the physician could not be compelled to testify, and in most he would not be permitted to do so.

CHARITABLE INSTITUTIONS FOR INEBRIATES.

Butler, Pa., May 23, 1904.

To the Editor:—Can you inform me of some good, reliable sanatorium or hospital for the care of alcoholic and opium cases, one in which a patient of very poor circumstances can be accommodated? Is there such a charitable institution in existence in this country?

Dr. R. L. Stackpole.

Marriages.

Bertram F. Alden, M.D., to Miss Leonie Gless, both of San Francisco, May 11.

David W. Reid, M.D., to Miss Harriette Swigart, both of Iola, Kan., May 11.

William O. Sheller, M.D., Big Rock, Ill., to Miss Emma Frost of Chicago, May 13.

Virgil Hammer, M.D., Luray, Va., to Miss Angie Pearl Bradley, at Luray, May 10.

Standish McCleary, M.D., Baltimore, to Miss Rose Ida Duker at Baltimore, May 12.

Llewellyn P. Barbour, M.D., Boulder, Colo., to Mrs. Young Scott, at Athens, Ill., May 17.

Charles Minor Cooper, M.D., San Francisco, to Miss Ella R. Goodall of Oakland, Cal., May 11.

Jay Lee Beebe, M.D., Lower Lake, Cal., to Miss H. Eva Poapst, at Anaheim, Cal., May 18.

Lyston D. Howe, M.D., Leonore, Ill., to Miss Laura Quinn, in Eagle Township, near Streator, Ill., May 11.

Edgar Morrison, M.D., to Miss Josephine Brown, both of Jackson, Mich., at Ann Arbor, Mich., May 11.

Deaths.

John Milton Duff, M.D. Jefferson Medical College, Philadelphia, 1874, a member of the American Medical Association and chairman of the Section on Obstetrics and Diseases of Women in 1894; member of the Medical Society of the State of Pennsylvania, the American Academy of Medicine, American Association of Obstetricians and Gynecologists, and many other medical societies; chief obstetrician and abdominal surgeon to the Rhineman Hospital, chief surgeon to the Southside Hospital, gynecologist to the Kaufman Clinic; professor of obstetrics and associate professor of the diseases of women in the Western Pennsylvania Medical College, widely known as a lecturer, teacher, writer, diagnostician and operator, died from malignant disease of the mouth and throat, for which operation was twice unsuccessfully performed, after a protracted illness, May 14, at his home in Pittsburg, aged 54.

James Grey Thomas, M.D. University of Pennsylvania, Philadelphia, 1856, a councilor of the Medical Association of the State of Alabama, and for several years president of the Mobile Medical Society; a surgeon in the Confederate service during the Civil War, prominent as a physician and surgeon throughout the south, and a member of the staff of the governor of Alabama, died at his home in Mobile, May 13, from inflammatory rheumatism, after an illness of six weeks, aged 69.

William H. McGee, M.D. Bellevue Hospital Medical College, New York City, 1872, a member of the Medical Society of New Jersey, and the Warren County Medical Society; ex-president of the latter, and for eighteen years its treasurer; surgeon for the Pennsylvania Railroad for sixteen years, died at his home in Belvidere, N. J., May 10, after an illness of more than three years, of chronic interstitial nephritis and cancer of the stomach, aged 56.

William A. McCoy, M.D. Medical College of Indiana, Indianapolis, 1872, a member of the American Medical Association, and secretary of the Jefferson County Medical Society, died at his home in Madison, Ind., May 8, from heart disease, after a prolonged illness, aged 60.

John Adams Carrol, M.D. Medical Department of Victoria College, Toronto, 1869, who retired from active practice in 1884 and thenceforth devoted himself to the study of the flora of the Niagara peninsula, died at his home in St. Catharines, Ont., March 25, aged 58.

Peter F. Stokes, M.D. Medical College of the State of South Carolina, Charleston, 1846, a member of the South Carolina legislature in 1852, and of the secession convention in 1860, died at his home near Branchville, S. C., May 16, after a long illness, aged 83.

A. Nash Johnston, M.D. Medical College of Virginia, Richmond, 1873, superintendent of schools of Rockbridge County, formerly state senator, died at his home near Natural Bridge, Va., May 10, from pneumonia, after a short illness, aged 55.

Rial Strickland, M.D. Albany (N. Y.) Medical College, 1839, once member of the Massachusetts House of Representatives, and thrice state senator in Connecticut, died at his home in Enfield, Conn., Dec. 5, 1903, from senile debility, aged 88.

Albert Nassau Cooper, M.D. College of Physicians and Surgeons of San Francisco, 1901, a member of the American Medical Association, died at his home in Bisbee, Ariz., April 27, from pneumonia, after an illness of seven days, aged 25.

Herbert Lindermann, M.D. Medico-Chirurgical College of Philadelphia, 1891, was found dead in the vestibule of his home in Philadelphia, May 15, aged 37. He had been ill a long time with nephritis, and died in a uremic convulsion.

Benjamin J. Clevenger, M.D. Medical College of Indiana, Indianapolis, 1873, for five years postmaster of Redkey, Ind., died at his home in that place, May 10, from dropsy, after an illness of two weeks, aged 55.

Cyrus Truman Meaker, M.D. Dartmouth Medical College, Hanover, N. H., 1887, a prominent dentist of Carbondale, Pa., died at his home in that city, May 9, from pneumonia, after a short illness, aged 57.

John N. D. Cloud, M.D. College of Physicians and Surgeons, New York City, 1883, county physician of Duval County, Fla., died at the Duval County Hospital, Jacksonville, May 7, from septicemia.

Daniel W. Tyndall, M.D. University of Michigan, Ann Arbor, 1864, a surgeon during the Civil War, died at his home in Taylor, Mo., May 16, from uremia, after an illness of three months, aged 67.

Edward A. Bair, M.D. University of Buffalo, N. Y., 1897, of South Buffalo, N. Y., died at the Buffalo Sisters of Charity Hospital, April 23, after a third operation, following appendicitis, aged 35.

J. A. Halteman, M.D. Germany, died at his home in Espanola, N. M., May 6, from congestion of the brain, due to injuries received in a runaway accident three weeks before, aged 60.

Henry H. Critchfield, M.D. Minnesota Hospital Medical College, Minneapolis, 1885, of Hunter, N. D., died suddenly at a hotel in Minneapolis, May 13, from heart disease, aged 43.

Bernard Mackay, M.D. University of Paris, France, a retired physician of New York City, was run over by a fire engine in New York City, May 12, and instantly killed, aged 71.

William E. Garnett, M.D. University of Louisville, 1869, of Cave City, Ky., died at Stanford, Ky., May 4, from disease of the stomach, after an illness of several months, aged 65.

Elbert Wallace Clark, M.D. Rush Medical College, Chicago, 1871, died at his home in St. Albans, W. Va., May 19, from general paresis, after an illness of three years, aged 55.

Nelson Fanning, M.D. Albany (N. Y.) Medical College, 1859, died May 17, at his home in Catskill, N. Y., from injuries received in a fall downstairs, two days before, aged 63.

Albert G. Pottle, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1871, died, May 5, at his home in Canaan, Vt., from appendicitis, after a short illness.

Thomas C. Robinson, M.D. Jefferson Medical College, Philadelphia, 1860, died from apoplexy at his home in Turtle Creek, Pa., May 15, after a brief illness, aged 67.

William P. Buckley, M.D. McGill University, Montreal, 1870, of Prescott, Ont., died in a hospital at Ogdensburg, N. Y., April 2, after undergoing a surgical operation.

Joseph F. Leroux, M.D. Laval University Medical Department, Quebec, 1883, died at his home in Montreal, May 14, from articular rheumatism, aged 55.

Dayton R. Black, M.D. Medical College of Indiana, Indianapolis, 1875, died at his home in Terre Haute, Ind., from pneumonia, May 15, aged 55.

Wilber Fisk Templeton, M.D. New York City, died at his home in Glover, Vt., from paralysis, May 7, after an illness of two weeks, aged 68.

R. G. Coleman, M.D. Medical College of Ohio, Cincinnati, 1867, died at his home in Monarch, Mo., May 12, after a long illness, aged 60.

Hugh H. Davis, M.D. University of Pennsylvania, Philadelphia, 1878, died at his home in Sonoma, Cal., May 8, from heart disease, aged 62.

John V. Curtis, M.D., a veteran of the Mexican and Civil wars, died at his home in Columbus, Ohio, May 12, from senile debility, aged 83.

Henry W. Strong, M.D. University of Michigan, Ann Arbor, 1864, died recently at his home in Byron Center, Mich., and was buried May 11.

Alexander Broadfoot, M.D. Toronto School of Medicine, 1884, died from tuberculosis at his home in Mondovi, Wis., February 14, aged 49.

Hiram Leach, M.D. Illinois, formerly of Fulton, Ill., died recently at Camanche, Iowa, aged 84, and was buried, May 11.

E. Stroup, M.D., postmaster of Nettleton, Mo., dropped dead from heart disease at his home in Nettleton, May 16, aged 60.

Henry Casper Schmitz, M.D. University of Berlin, Germany, 1856, died at his home in Brooklyn, N. Y., May 11, aged 72.

Marshall D. Spencer, M.D. Broome County (N. Y.) Medical Society, 1859, died at his home in Guilford, N. Y., May 2.

John T. Masoner, M.D. Chattanooga (Tenn.) Medical College, 1896, died at his home near Big Springs, Tenn., May 12.

James Torrington, M.D., for many years a practitioner on Peak's Island, Maine, died in Toronto, May 6, aged 93.

Ernest Carter, M.D., L.R.C.S. Edinburgh, 1888, district coroner, died recently at Moosomin, Assiniboia, N. W. T.

Ezekiel W. Bullard, M.D. Missouri, 1877, died recently, and was buried at Pawnee City, Neb., May 18.

John H. Peacock, M.D. Philadelphia, 1864, died at his home in Wilkesbarre, Pa., May 11, aged 80.

Francis Clunie Sibbald, M.D., retired, died at his home in Sutton, Ont., April 7, aged 80.

Chester J. Britton, M.D. Indiana, 1901, of Attica, Ind., was found dead in bed, May 9.

Isaiah Brothers, M.D. Ohio, 1857, died at his home in Youngstown, May 1, aged 73.

Deaths Abroad.

W. His, M.D., professor of anatomy at Leipsic, died there April 30, aged 72. He was one of the founders of the *Archiv. f. Anthropologie* and later of the *Zeitschrift f. Anatomie*, and was the editor of the latter until it merged with the *Archiv f. Anatomie und Physiologie.* He was also a prime mover in the recent endeavor to introduce a uniform anatomic nomenclature.

E. Duclaux, M.D., director of the Pasteur Institute at Paris, and professor of biologic chemistry, died at Paris, May 3, aged 64. His original researches in physics, meteorology and chemistry are all important contributions to science, but his name is best known from his work in microbiology. His "*Ferments et Maladies*," published in 1882, was one of the pioneers in this line. His "*Traité de Microbiologie*," 1898, is a classic, and the journal he founded in 1887, *Annales de l'Institut Pasteur*, has always taken a high rank.

Miscellany.

ORGANIZATION IN GERMANY.

Governmental Provisions for the Welfare of the German Medical Profession.

The importance and value of a united and well organized medical profession has been long recognized in Germany, and various legislative means have been adopted to accomplish this result. The system as it now stands resembles somewhat our own local, state and national organization, but in Germany it is compulsory on all physicians. It is supplemented by disciplinary tribunals for ethical questions, and each local organization is accumulating an endowment by its annual dues of $1 to $3, which fund is to be used in aiding physicians or their families in need, in prosecuting impostors and in other matters affecting the welfare of the profession. The above organization is entirely outside of the scientific medical societies, which are like similar strictly scientific bodies elsewhere.

Prussia passed a law, May 25, 1885, which made compulsory the organization of all registered physicians throughout the country. It provided for the grouping of all physicians residing in a province into what are called medical chambers (*Aerztekammer*), the aim of which was stated to be "to promote from every point of view the scientific, material and moral interests of the medical profession." In order to still further foster the spirit of professional unity among medical men a decree in 1896 established a central committee composed of delegates from all the Prussian chambers, according to membership. This central house of delegates is the intermediary between the provincial chambers and the state department which has charge of medical affairs, the universities, etc., being all state institutions in Germany. This central committee has a permanent office at Berlin. Once a year also the members of the medical chambers or their delegates meet at some central point for their annual assembly (*Aerztetag*).

Every physician, without exception, whether he belongs to a scientific society or not, whether he practices or does not practice, whether he is assistant in a hospital or has retired from practice, is required to pay his annual dues to the medical chamber of his province and is subject to its disciplinary court. The medical chamber is entitled by law to use the funds thus provided, as it deems best for the welfare of the profession. The government did not attempt to establish a code of ethics for the profession. This was left for the medical chambers, and the rules they adopt are binding for the physicians in their several jurisdictions. The rules are made by the physicians themselves, assembled in their special medical chamber, and thus conform to the local requirements. In this democratic way a code of ethics for each community is being tentatively worked out. The last four *years have* realized great progress in this line.

When one chamber adopts a rule that proves to work satisfactorily it is adopted by other chambers, and in this way the various medical chambers act in concert. The various chambers report to the government in regard to epidemics, patent medicines, midwifery, impostors, etc., and prosecute quacks in the common courts, investigate the claims to the title of "Doctor," and other questions affecting the profession. Some of the medical chambers have laid down rules for advertising when a physician locates in a place or returns after an absence, or wishes to advertise the medical institution or sanatorium of which he is proprietor. Some chambers have adopted regulations in regard to specialist practice. No specialist is allowed to do general practice. Specialists now doing a general practice are allowed three years in which to abandon the latter. A physician who wishes to give up his general practice and devote himself to a specialty has to offer testimony to the effect that he has been employed in a hospital for that specialty for several years, in other words, he has to prove himself qualified for the title of specialist. Throughout Germany there is a general disapproval of the so-called "vacation specialist," who goes to some university for the summer, takes a post-graduate course and then returns to his little town and wishes to play the specialist. The Prussian authorities are now collecting a list of all the specialists in the country. The specialist physicians of Berlin have already received a question blank to be filled out and returned, giving name, age, year, date of license to practice, and the specialty practiced, with details as to the training for the specialty, the years during which it was being studied, the institution and the instructor. The question is also asked as to how long the specialty has been practiced as such, and further whether the specialist has his own hospital or clinic or whether he is connected with a public institution, and if so, in what capacity.

PENALTIES FOR DISREGARD OF ETHICAL QUESTIONS.

This system of provincial medical chambers and the central house of delegates is supplemented by the courts of honor, which are also organized, one in each province, with a central supreme court of appeals in Berlin. They were organized in accordance with a law passed Nov. 25, 1899. Each court of honor comprises the president and three members of the medical chamber with one outsider occupying a judicial position and appointed by the president of the medical chamber for a term of six years. Five members constitute a quorum, but no penalty can be pronounced without a majority of four-fifths of the votes. The supreme court of honor comprises the chief of the state department that has charge of medical matters, four members of the central house of delegates and two outside physicians, the latter appointed with two substitutes by the king.

Complaints of one physician against another or from a layman against a physician must be laid before the court of honor of the medical chamber of the province. *Both parties have the* privilege of appeal to the supreme court of honor which gives the final decision. The penalties are: 1, *Warning*; 2, censure; 3, fines not to exced $750, and 4, *suspension from the* right to vote or hold office in the medical chambers, eventually with public announcement of the sentence. The decisions of the supreme court of honor have frequently been referred to in The Journal, and those having more than local interest have generally been given in full, as, for instance, on page 660.

Criminal proceedings of course come under the jurisdiction of the common courts, and political, scientific or religious opinions or acts can never be a cause for prosecution in the courts of honor. The Saxony medical chamber was recently discussing the question as to whether the expenses of frivolous and ungrounded charges brought by one physician against another should be paid by the complainant. This elicited the statement from one who knew, that fully 23.5 per cent. of all the denuntions in the courts of honor *come under this* head. Printed copies of all the regulations adopted by the medical chamber of a province are given to all the members and newcomers.

GENERAL INFLUENCE OF ORGANIZATION.

Through the system of medical chambers the profession exerts an influence on all legislative questions concerning drugs, hygienic and sanitary questions and medico-political affairs in general. The state authorities confer with the different medical chambers or the central body, and on their approval depends the acceptance by congress of the proposed legislation. This influence has been beneficially felt in the decree regulating hypnotic exhibitions and many other useful measures. The other German states and Austria have medical chambers modeled on those of Prussia, but differing in certain respects.

THE FUNDS OF THE MEDICAL CHAMBERS.

The medical chamber receives the fines imposed by the court of honor; it is also authorized to receive bequests, etc., and thus, in addition to the dues, a fund is accumulating to be held in reserve to be used in prosecuting dishonorable practitioners, to relieve physicians or their families temporarily in distress and for other expenses voted for matters affecting the welfare of the profession. Each chamber has the right to dispose of this fund as it deems wise for the good of the profession. Mileage is paid to the members and a small daily fee for attendance. The expenses of the central house of delegates are also paid by assessments on the various medical chambers. We notice in the report of a recent meeting of the Westphalia medical chamber that the suggestion was made that physicians should pay into the treasury a sum corresponding to the regular fees whenever a member of their family has been carried through a sickness by some colleague.

CONTRACT PRACTICE.

The German law of 1883 made insurance against sickness and old age compulsory on all working people receiving less than a certain wage. This is one of the greatest reformatory social movements ever instituted, and its results are far-reaching in every direction. The only thing criticised about it is that the limit of old age is set at 70, while only a small percentage of the working classes reach this age. The limit will probably be reduced to 60 in time, as funds accumulate. The insurance against sickness is not yet compulsory on all working people under a certain wage, but is for most of them.

In consequence of this legislation there have been organized 40 insurance companies, with a total of 23,000 local branches for various trades, etc., and the millionth beneficiary was recently registered. The local sickness insurance companies are entirely independent of the government. They make contracts with physicians to suit themselves and have frequently had nature healers and magnetopaths on their list. The less money they have to pay for medical attendance, the more they have in reserve and the smaller are the assessments of the members. Physicians throughout the country found they were being ground down by these sickness insurance companies, and notwithstanding the extensive system of organization of medical men in the medical chambers nothing effectual was done to better this state of things. The need of some organization to supply financial aid to the contract doctors in their struggle with the societies was realized, and the Leipsic *Verband* was founded for this purpose. Its full title is the *Verband der Aertze Deutschlands zur Wahrung ihrer wirthschaftlichen Interessen*. It has frequently been mentioned in THE JOURNAL. The moving spirit in it is Dr. Hartmann, Leipzig-Connewitz, Südstrasse 121. It now has 15,142 members, with 84 branches, and is aiding many physicians all over Germany in their revolt against the low fees granted by the societies. Another point of controversy is the question of the "free choice" of a physician, or the American plan, as it is called. The insurance societies compelled their policy-holders to employ the physician under contract to them, and would not pay the fee if they called on an outsider. The contract physician sometimes lived miles away from the patient, and may have owed his appointment to some "pull" or other influence. In those places where the "free choice" has been introduced the patient has a choice of different physicians, specialists, etc. The minimum fee is established by the medical chamber and the insurance companies are required to pay this sum. The companies unwilling to pay it are boycotted by the members of the medical chamber, no member being allowed to supply medical services to the society or make contracts with them. Matters were brought to a crisis in this contract practice last spring when a new law went into effect, doubling the length of the period of medical attendance, increasing it from thirteen to twenty-six weeks. Some of the companies would not increase the remuneration of their medical attendants to correspond, and in a large number of places they resigned in a body. The societies found themselves unable to procure other reputable physicians to fill their places, and at several important points the municipal authorities interfered and ordered them to supply the needed number of qualified medical attendants within a certain time limit or the mayor would reinstate the former physicians at their own terms, which was accordingly done when the days of grace expired. The profession regard the use of the term "qualified physicians" in this order as holding out great promise for the future that the state will interfere to protect the profession from further oppression and discountenance contracts with quacks. Some of the details of this conflict between the contract doctors and the insurance societies were published in the news columns on page 543.

The physicians of Bavaria took such a firmly united stand last spring that the companies speedily yielded and accepted their terms, the victory being complete all along the line.

Homeopathy is a subject which in England, at any rate, is so thoroughly dead, says the *British Medical Journal*, that it might safely be buried without fear of rebuke from the Anti-premature Burial Association; nor have we any desire to revive it.

State Boards of Registration

COMING EXAMINATIONS.

Nebraska State Board of Health, June 1-2, Creighton Medical College, Omaha. Secretary. Geo. H. Brash, M.D., Beatrice.

New Mexico Board of Health, Santa Fe, June 6. Secretary, D. B. Black, M.D., Las Vegas.

Iowa State Board of Medical Examiners, June 6-7, Des Moines, June 9-10, Iowa City. Secretary, J. F. Kennedy, M.D., Des Moines.

Minnesota State Board of Medical Examiners, Capitol Building, St. Paul, June 7-9. Secretary, C. J. Ringnell, M.D., Minneapolis.

Michigan State Board of Registration in Medicine, Lansing, June 14. Secretary, B. D. Harison, M.D., Sault Ste. Marie.

Ohio State Board of Medical Registration and Examination, Columbus, June 14-16. Secretary, Frank Winders, M.D., State House, Columbus.

Board of Medical Examiners for the State of Texas, Houston, June 15. Secretary, M. M. Smith, M.D., Austin.

Board of Medical Examiners of Maryland, Lehman's Hall, Baltimore, June 15-18. Secretary, J. McP. Scott, Hagerstown.

Missouri State Board of Health, Kansas City, June 20-22. Secretary, W. F. Morrow, M.D., Kansas City.

Medical Society of Delaware, Dover, and the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, June 21. Secretary Medical Council. P. W. Tomlinson, M.D., Wilmington.

New Jersey State Board of Medical Examiners, June 21-22, Trenton. Secretary, E. L. B. Godfrey, M.D., Camden.

Medical Examining Board of Virginia, June 21-24, Richmond. Secretary, R. S. Martin, M.D., Stuart.

State Board of Medical Examiners of South Carolina, State House, Columbia, June 28. Secretary, W. M. Lester, Columbia.

State Medical Society of Pennsylvania, June 28 30, Philadelphia and Pittsburg. Secretary, Isaac B. Brown, M.D., Harrisburg.

Territorial Medical Examining Board of Oklahoma, Guthrie, June 29. Secretary, E. E. Cowdrick, M.D., Enid.

Minnesota Report.—Dr. C. J. Ringnell, secretary of the Minnesota State Board of Medical Examiners, reports that at the written examination held at St. Paul, April 5, 6 and 7, 1904, 95 questions were asked on 12 subjects, and a percentage of 75 was required. Of the 12 who were examined 6 passed and 6 failed.

College.	Year Grad.	Per Cent.
PASSED.		
University of Minnesota	(1903)	81.3, 79.3
College of Physicians and Surgeons, Chicago	(1903)	79.0

Meharry Medical College	(1904)	74, 68
Chattanooga Medical College		72

The questions asked were as follows:

CHEMISTRY.

1. Give the symbol, atomic weight and valence of each of five elements. 2. Distinguish between id and ate terminations. Give formula for potassium chlorid and potassium chlorate. 3. How many minims in one c.c. of water? 4. What is a hydracid? an oxyacid? 5. What is an empirical formula?

PHYSIOLOGY.

1. Give principal events in gastric digestion. 2. Define blood pressure. State the factors which increase and decrease blood pressure. 3. State, approximately, the amount of oxygen consumed and the amount of carbon dioxid produced in respiration in twenty-four hours. 4. Describe the secreting structures of the kidneys. 5. Give origin and distribution of sympathetic nerve fibers. Name the three classes into which its ganglia are divided.

MATERIA MEDICA AND THERAPEUTICS.

1. Give symbols of minims, fl. drams, fl. ounces, pint, gallon. 2. Give difference between anesthetic and analgesic. Examples of each. 3. (*a*) Define motor excitants. (*b*) Name the most important. (*c*) Therapeutics and doses. 4. (*a*) Source of turpentine, (*b*) its composition, (*c*) action, external and internal, (*d*) its principal preparation, (*e*) therapeutics and doses. 5. Write a prescription for gastric fermentation containing carbolic acid, bismuth subnitrate, glycerin, peppermint water.

GYNECOLOGY.

1. Describe the technic for a simple curettage, for curettage after an abortion, for carcinoma which can not be removed radically. 2. Describe an operation for lacerated perineum, for lacerated cervix. 3. Describe an operation for cystocele, rectocele and prolapsed uterus to second degree. 4. Give differential diagnosis between ectopic gestation, pyosalpinx and appendicitis. 5. Name some of the causes of pelvic suppuration. State how you would treat an ovarian or tubal abscess attached to vaginal wall.

SURGERY.

1. Describe an amputation at lower third of the thigh. 2. What is surgical shock and how would you treat it? 3. What is fracture; what is dislocation; how would you treat a compound, comminuted fracture of the leg at its middle third? 4. What is varicocele; hydrocele? Describe operation for both conditions. 5. What is hernia? Describe an operation for radical cure for inguinal hernia.

PRACTICE.

1. Give etiology of polyomyelitis. (*a*) give some of the most prominent symptoms. (*b*) give location of lesion. 2. Give the most distinguishing symptoms of smallpox; give the three forms and types of each. 3. Give etiology and treatment of lobar pneumonia. 4. What is the essential cause of rachitis? Give treatment. 5. Location of the lesion in acute dysentery in children. Give treatment.

OBSTETRICS.

1. Diagnose placenta previa. Describe method of treating same. 2. Describe method of handling case of post-partum hemorrhage. 3. Give method of handling puerperal eclampsia. 4. Name the three stages of labor. Describe beginning and termination of each. 5. Give the presumptive and certain signs of labor.

DIAGNOSIS.

1. What is vocal fremitus? What conditions: (*a*) increase vocal fremitus, (*b*) diminish vocal fremitus? 2. Mention the aids to diagnosis that are of practical use in medicine and surgery. 3. Describe the diagnostic characteristics of acute appendicitis. 4. Differentiate rheumatic arthritis and joint tuberculosis. 5. Differentiate acute cerebral meningitis from syphilitic gumma.

ANATOMY.

1. (*a*) Describe the frontal bone and (*b*) name its articulations. 2. (*a*) Give the names of the muscles of the thigh and (*b*) state the origin, insertion and action of any one of the muscles mentioned. 3. Describe the origin, course and distribution of the renal arteries. 4. (*a*) Describe the portal system of veins and (*b*) give portal circulation. 5. Describe the sympathetic nerve, naming and locating the principal ganglia. 6. Give the anatomy of the skin and of its appendages.

PATHOLOGY.

1. Give pathology of interstitial nephritis. 2. Define arthritis deformans and give its morbid anatomy. 3. Discuss the patho- [illegible] erpes zoster. 4. Describe pus and give its [illegible]. Name the bacteria usually associated with [illegible] and suppurative processes.

An examination was also held at Augusta, April 2, 1904, at which 50 questions were asked on 10 subjects, and a percentage of 75 was required. All of the 32 who were examined passed.

PASSED.

College.	Year Grad.	Per Cent.
University of Georgia	(1903) (1904)	80, 82 80, 86, 80, 80, 85, 84, 92, 83, 78, 85, 83, 79, 84, 82, 80, 86, 77, 79, 80, 81, 83, 83, 80, 86, 83.
University of the South, Sewanee, Tenn.	(1901)	83
Maryland Medical College	(1903)	87
University of Nashville, Tenn.	(1904)	84
Memphis Hospital Medical College	(1903)	79
Society of Apothecaries, London, England	(1889)	92
College of Physicians and Surgeons, Baltimore		88

The questions asked were as follows:

CHEMISTRY.

1. Give the formula of each of three compounds and give name of each 2. Distinguish between ous and ic terminations. Give formula for mercurous and mercuric chlorid. 3. State approximately, how many grains in two decigrams. 5. What is a graphic formula? Illustrate.

PHYSIOLOGY.

1. State the composition and functions of pancreatic juice. 2. What are the forces which keep the blood in circulation? 3. Where and by what mechanism does the exchange of gases take place in respiration? 4. State the average amount of water, urea and uric acid excreted by the kidneys in twenty-four hours. 5. Briefly give the arrangement and functions of the sympathetic nervous system.

ANATOMY.

1. State what organs are partly and what are entirely invested by the peritoneal membrane. Describe the reflections of the pelvic peritoneum in the female. 2. State the origin, the insertion, the action and the nerve and the blood supply of the pectoralis major muscle. 3. Describe the axillary artery and mention its branches. 4. Describe the principal fissures of the brain. 5. Describe the ductus communis choledochus. Where and into what does it empty? 6. Give gross anatomy of spinal column.

OBSTETRICS.

1. Differentiate between vertex and breech presentation. 2. Name some of the most common causes of ante-partem hemorrhage. 3. What are the most common causes of post-partum hemorrhage? (*a*) How would you manage a case? 4. Give definition of puerperal fever. (*a*) Give prophylactic and curative treatment. 5. Etiology of crural phlebitis. What would be your treatment?

GYNECOLOGY.

1. Name the female organs of generation. Describe briefly the fallopian tubes. 2. What is meant by menstruation, fecundation and impregnation? Define dysmenorrhea and name some of the commonest cause of this condition. 3. Describe some of the positions used in the diagnosis of pelvic diseases. 4. Outline briefly technic for a plastic operation on the generative organs. 5. Outline briefly technic of a celiotomy. Describe the necessary preparatory treatment of patient.

SURGERY.

1. Give indications for skin grafting and state method of doing it. 2. Give indications for and state method of doing colotomy. 3. What is inflammation? How may it terminate? 4. Give diagnosis and treatment of erysipelas. 5. What is empyema and how would you diagnose and treat it?

PATHOLOGY.

1. Describe the process of wound repair. 2. What are toxins? How does the system dispose of toxins? 3. State some of the structural changes that may occur in red blood corpuscles. 4. What structural changes occur in cirrhosis of the liver? 5. Describe (*a*) coccus, (*b*) bacillus, (*c*) the spirillum.

PRACTICE.

1. Give chief etiologic factors in acute gastroenteritis of childhood, (*a*) give both prophylactic and curative treatment. 2. Give symptoms of intussusception in children, (*a*) give treatment. 3. Contrast the type of rheumatism in adults and children, clinically. 4. Define diabetes mellitus. 5. What is sun-stroke? (*a*) How would you treat a case?

MATERIA MEDICA AND THERAPEUTICS.

1. (*a*) Indications to be kept in mind in the treatment of poisoning. (*b*) Name a deadly vegetable and mineral poison very frequently used in practice, with doses of same. 2. (*a*) Source of ichthyol, (*b*) characters, (*c*) therapeutics, (*d*) dose. 3. Write a prescription for ascarides containing santonin, calomel and sugar. 4. (*a*) Give the action of chloral, (*b*) symptoms of poisoning by same, with treatment, (*c*) therapeutics. 5. (*a*) Name three acids from vegetable and three from animal kingdom, (*b*) action of acids, (*c*) therapeutics and doses.

DIAGNOSIS.

1. Make a diagnosis of dislocated movable kidney (floating kidney.) 2. Give the procedure of examining sputum for tubercle bacilli. 3. Give some of the pathologic changes occurring in the later stages of syphilis. 4. What are the intestinal changes in chronic enteritis? 5. Diagnose and treat a case of cystitis, (*a*) acute and (*b*) chronic.

Association News.

THE ATLANTIC CITY SESSION.

Railroad Rates—How to Register—New York Society Members Invited—Other Details.

The Atlantic City session is but ten days away, and everything points to a large and enthusiastic gathering. The rate of one fare for the round trip has been granted from the Pacifi coast, from the central, the western and the southeastern portions of the United States, while in New England a rate of one and one-third fare for the round trip on the certificate plan has been granted. Tickets are to be on sale June 1, 2, 4, 5 and 6. In the Central and Western Passenger Association territory, tickets will also be sold Tuesday, May 31; at points still farther west tickets will be sold at correspondingly earlier dates.

The rate from New York City will be $4.25 for the round trip. Tickets will be sold June 2, 3, 5 and 6, and will be good for return from June 4 to 13. The rate from Chicago will be $20.25.

No stop-over will be allowed at Philadelphia on the going trip. This is a change in the plan, as we have been informed by the railroad officials since the last issue of THE JOURNAL. As the rules concerning stop-overs now stand, stop-over will be allowed at Philadelphia, Baltimore and Washington on the return trip only, within the final limit of the ticket by deposit of the ticket immediately on arrival at the place at which it is desired to stop. Another change in the announcement of last week is as follows: We stated that the Grand Trunk Railroad would run special sleepers to Atlantic City. On this we were misinformed, as the Grand Trunk sleepers will run only to Philadelphia, at which point there will be a change of cars. In other respects, the announcement in THE JOURNAL of May 21 is correct, and to it our readers are referred for further particulars. A special train leaves Chicago on the Pennsylvania Lines Sunday, June 5, at 2 p. m., and will run to Atlantic City without change.

The above information, while applying to only two or three points of departure, will give an idea of the rates from all over the country. Members desiring specific information should apply to their local ticket agent, who will have full particulars in the form of circulars, etc., and information that can be had only at the local point.

Registration at Atlantic City—Some Suggestions.

The Registration Bureau will be open for the registration of members at 8 o'clock Monday morning, June 6, and will remain open until 5:30 p. m. These hours will prevail each day until Friday, June 10, when the hours will be from 9 to 11 a. m., the bureau closing at 11.

Members will do well to go to their hotels immediately on arriving, and, having located, to the bureau and register.

The method of registration is as follows: Members will find cards at the bureau, which they will fill out. These cards are double; the upper relates particularly to registration and the attached card is intended for two purposes—the first to indicate the section with which the member desires to affiliate himself, and the second will be the basis for the list that will be published in THE JOURNAL after the session. When these cards are filled out, the member will present them at the indicated window, and if he has paid his dues for 1904, he will show his "pocket card." If he has not paid his dues for 1904, he will present the registration cards at a cash window and there pay the amount due.

Members are urged to take with them their pocket cards. It will save them, as well as the clerks at the Registration Bureau, much annoying delay.

NEW MEMBERS.

Physicians who desire to join the Association at Atlantic City must bring with them a certificate showing they are members of their state association or of one of its component branches. This is important. The certificate should be signed by the president and secretary of the state association or by the president and secretary of a component society.

House of Delegates.

The House of Delegates will be called to order promptly at 10 a. m., Monday, June 6, at the High School Building. The Committee on Credentials and Registration will be at the High School Building at 9 a. m. for the registration of the members of the House of Delegates. Members are urged to be present at 9 o'clock, or as soon after as possible, so that the registration may be completed by the time the meeting is called to order.

Rush Monument Dedication.

The announcement last week that the dedication of the Rush monument would be at 4 p. m., Saturday, June 11, was an error. The hour fixed is 5 p. m.

Place of Session in 1905.

Portland, Ore., Los Angeles, Cal., and Hot Springs, Ark., are among the many cities desirous of entertaining the American Medical Association in 1905. We mention the names as matters of news, and without any official announcement of their proposal. We quote here as of interest in this connection what *Northwest Medicine* (Seattle, Wash.) says concerning the candidacy of Portland:

SHALL THE AMERICAN MEDICAL ASSOCIATION VISIT PORTLAND?

> We are pleased to note that the Portland profession has worked vigorously for the meeting in 1905. While the result is still in the air, our eastern friends have been evidently impressed with the project of going west again. In order not to appear behind their neighbors to the north, the profession in southern California came into line and have solicited the meeting for their state. We feel little uneasiness on this account. On the contrary, it will help the interests of the northwest by calling attention more strongly to the Pacific coast. If these two sections were alone in competition for the desired meeting we would peacefully permit the question to be decided on the respective attractions of the two.
>
> When the invitation of Portland was first presented the chief question seemed to hinge on the ability of that city to entertain the visitors. We believe this matter will be satisfactorily handled. In connection with the Lewis and Clark Fair, accommodations will be provided that will amply satisfy all demands. If the fair were not then in contemplation, the question of limited accommodations would have more force.
>
> The objection on the score of distance seems to us westerners somewhat of a joke. The man of maturity who has not crossed the continent and thus obtained a realizing sense of the extent and magnitude of his native land, ought to retire from practice long enough to educate himself and be able to intelligently discuss, from personal knowledge, the attractions of the richest and greatest country the Creator has presented to mankind, his own inheritance. The *Medical Sentinel* has recently depicted in glowing terms the beauties that Nature has so generously bestowed on its home city and surroundings. While not wishing to detract one whit from the truths therein contained, we wish to call the attention of our eastern visitors to the fact that Puget Sound and Alaska offer scenery, of water, of mountain and forest combinations, of such magnitude and variety, that the familiar and famed landscapes of the Old World are dwarfed in comparison. The Alaska trip alone is the recollection of a lifetime. Naturally a large proportion of the visitors will plan to return by a northern route and inspect all that is available in the allotted time. Opportunities to this end will be provided by those familiar with local conditions and attractions.
>
> Justice to the Pacific coast seems to demand the meeting of 1905 in the far west. We shall continue to trust and urge that the officials of the Association may select Portland for this meeting, realizing that circumstances so favorable as at the present time for holding a session in this section may not again arise.

Invitation to Members of the New York State Medical Society.

Dr. Musser, President-elect of the American Medical Association, has sent the following letter to the president of the Medical Society of the State of New York:

> PHILADELPHIA, May 23, 1904.
>
> *My Dear Dr. Wey:*—At the suggestion of some members of the New York State Medical Association, and in accordance with my own desires, I hereby extend to you and, through you, to the members of the Medical Society of the State of New York, an invitation to attend the session of the American Medical Association, at Atlantic City, June 7 to 10, and to take part in the scientific proceedings.
>
> Trusting to have the opportunity of meeting you all, I am
>
> Very sincerely, J. H. MUSSER.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending May 21, 1904:

Miller, R. B., asst.-surgeon, leave extended one month.

Bingham, E. G., asst.-surgeon, left Ord Barracks, Cal., with squadron Ninth Cavalry en route to Sequoia and General Grant Parks, Cal., for duty.

Pipes, Henry F., asst.-surgeon, left Ord Barracks, Cal., with squadron Ninth Cavalry en route to Yosemite, National Park, Cal., for duty.

Waterhouse, S. M., asst.-surgeon, reports for duty at Fort Worden, Wash.

Ford, Clyde S., asst.-surgeon, returned to Fort H. G. Wright, N. Y., from leave of absence.

Winter, Francis A., asst.-surgeon, left Fort Huachuca, Ariz., with B, Fifth Cavalry, changing station to Fort Grant, Ariz.

McAndrew, P. H., asst.-surgeon, returned to station at Jefferson Barracks, Mo., from leave of absence.

Stiles, Henry R., Munson, Edward L., Sweazey, Verge E. and Krebs, Lloyd Le Roy, asst.-surgeons, arrived at San Francisco, left Manila on the *Sherman* April 15, 1904.

Winn, Robert N., asst.-surgeon, relieved from duty at Fort Grant, Ariz., and ordered to Fort McDowell, Cal., for duty at the depot of recruits and casuals.

Murray, Alexander, asst.-surgeon, relieved from duty as surgeon on the U. S. Army transport *Sheridan* and ordered to General Hospital, Fort Bayard, N. M., for duty.

Lynch, Charles, asst.-surgeon, detailed member of the General Staff Corps. Captain Lynch will report in person to the chief of staff in Washington.

Munson, Edward L., asst.-surgeon, relieved from further duty in the Philippine Division and ordered to U. S. General Hospital, Fort Bayard, N. M., for duty.

Hogue, Gustavus I., contract surgeon, left Fort McDowell, Cal., May 9 on leave of absence for one month, with permission to apply for an extension of one month.

Halsell, John F., contract surgeon, granted leave of absence for one month from Fort McIntosh, Texas, with permission to apply for an extension of one month.

Wall, Francis M., contract surgeon, left Camp George H. Thomas, Ga., May 15 for duty at target range, Waco, Ga.

Van Kirk, Harry H., contract surgeon, ordered to proceed, when relieved at Fort Washakie, Wyo., to Fort Sill, Okla., for duty.

Davis, William R., contract surgeon, assigned to duty as surgeon of the transport *Sheridan*.

Peck, Luke B., contract surgeon, ordered to proceed from Jersey City, N. J., to Fort Andrews, Mass., for duty.

McMillan, Clemens W., contract surgeon, left Fort Ethan Allen, Vt., May 16 for temporary duty at target range, Fort Niagara, N. Y.; whence he is to return to his proper station, Fort Myer, Va.

Kennedy, James S., contract surgeon, relieved from duty at the depot of recruits and casuals, Fort McDowell, Cal., and ordered to Fort Grant, Ariz., for duty.

Dewey, Frederick S., contract surgeon, assigned to duty at Oklahoma City, Okla., as attending surgeon and examiner of recruits.

Decker, George M., contract dental surgeon, ordered to proceed to Forts Du Chesne and Douglas, Utah, for professional duty, and then to return to his proper station, Fort Logan, Colo.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending May 21, 1904:

Snyder, J. J., P. A. surgeon, detached from the *Kearsarge* and ordered to the *Maine*.

Bucher, W. H., surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the Naval Hospital, Yokohama, Japan.

Thompson, E., surgeon, commissioned surgeon, with the rank of lieutenant commander, from March 3, 1903.

Furlong F. M., P. A. surgeon, detached from duty with the marine battalion on the *Dixie* and ordered home and to await orders.

Butler, C. St. J., P. A. surgeon, commissioned P. A. surgeon with the rank of lieutenant, from Oct. 28, 1903.

Marcour, R. O., asst.-surgeon, detached from duty with the marine battalion on the *Dixie* and ordered to the *Hancock*.

Rossiter, P. S., asst.-surgeon, detached from the Naval Recruiting Station, Baltimore, and ordered to the Naval Station, Honolulu, H. I., sailing from San Francisco via steamer *Abarenda*, June 4.

Owens, W. D., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant, junior grade, from May 17, 1904.

Sellers, F. E., A. A. surgeon, appointed A. A. surgeon from May 17.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended May 19, 1904:

Carter, H. R., surgeon, to report at Washington, D. C., for special temporary duty.

Woodward, R. M., surgeon, granted leave of absence for three months from June 14.

Eager, J. M., P. A. surgeon, reassigned to duty at the port of Naples, Italy, effective March 25, 1904.

Francis, Edward, asst.-surgeon, to proceed to Martinsburg, W. Va., for special temporary duty.

Burkhalter, J. T., asst.-surgeon, ten days' extension of leave of absence, granted by Bureau telegram of May 9, 1904, revoked.

Alexander, E., A. A. surgeon, granted leave of absence for seven days from May 19.

Kennard, K. S., A. A. surgeon, granted leave of absence for fourteen days from May 22.

Walker, R. T., A. A. surgeon, granted leave of absence for four days from May 31.

Walkley, W. S., A. A. surgeon, granted leave of absence for nine days from May 24.

Rodman, J. C., A. A. surgeon, granted leave of absence for four days from May 24.

Carlton, C. G., pharmacist, granted leave of absence for thirty days from June 1.

Bierman, C. H., pharmacist, granted leave of absence, on account of sickness, for one day (May 9).

Van Ness, G. L., Jr., pharmacist, granted leave of absence for thirty days from June 1.

BOARDS CONVENED.

Board convened at Baltimore, May 18, 1904, for the physical examination of cadets in the Revenue-Cutter Service. Detail for the board: Surgeon H. R. Carter, chairman, Asst.-Surgeon C. W. Wille, recorder.

Board convened at Stapleton, N. Y., May 18, 1904, for the physical examination of an officer of the Revenue-Cutter Service Detail for the board: Surgeon Preston H. Bailhache, chairman; P. A. Surgeon A. C. Smith, recorder.

Board convened at Washington D. C., May 18, 1904, for the physical examination of applicants for appointment in the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon-General L. L. Williams, chairman; Asst.-Surgeon-General W. J. Pettus, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended May 21, 1904:

SMALLPOX—UNITED STATES.

California: Los Angeles, April 30-May 7, 1 case; San Francisco, April 24-May 1, 1 case.

District of Columbia: Washington, April 30-May 14, 8 cases.

Florida: Jacksonville, May 7-14, 1 case.

Illinois: Chicago, May 7-14, 11 cases; Danville, April 30-May 7, 2 cases.

Indiana: South Bend, May 7-14, 8 cases.

Kentucky: Covington, May 7-14, 3 cases.

Louisiana: New Orleans, May 7-14, 16 cases, 8 imported.

Maine: Jonesport, May 16, present.

Maryland: Baltimore, May 7-14, 1 cases, 1 death.

Michigan: May 7-14, Detroit, 5 cases; Grand Rapids, 5 cases.

Missouri: St. Louis, May 7-14, 14 cases, 4 deaths.

Nebraska: Omaha, May 7-14, 3 cases.

New Hampshire: Manchester, May 7-14, 4 cases.

New York: May 7-14, Buffalo, 2 cases; New York, 2 cases.

Ohio: May 6-13, Cincinnati, 7 cases; Cleveland, 2 cases, 1 death; Dayton, May 7-14, 12 cases.

Pennsylvania: May 7-14, Norristown, 1 case; Philadelphia, 27 cases, 5 deaths; Pittsburg, 2 deaths.

South Carolina: Charleston, May 7-14, 1 case.

Tennessee: May 7-14, Memphis, 16 cases; Nashville, 4 cases.

Wisconsin: Milwaukee, May 7-14, 8 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, April 2-9, 2 cases, 2 deaths.

SMALLPOX—FOREIGN.

Austria: Prague, April 23-30, 7 cases.

Belgium: Antwerp, April 23-30, 13 cases, 8 deaths.

Brazil: Bahia, April 8-23, 6 cases.

Canada: May 7-14, Sydney, 17, to date 61; Winnipeg, 1 case.

Colombia: Barranquilla, April 24-30, 2 deaths.

France: Paris, April 16-30, 27 cases, 2 deaths; Rheims, April 24 May 1, 1 death.

Germany: Barmen, April 22 29, 4 cases on S. S. Wittikind.

Great Britain: Birmingham, April 30-May 7, 1 case; Glasgow, April 29-May 6, 22 cases, 3 deaths; April 23-30, Hull, 3 cases; Liverpool, 7 cases; April 16-30, London, 35 cases, 4 deaths; Manchester, 10 cases, 3 deaths; New Castle-on-Tyne, 18 cases, 1 death; Nottingham, 9 cases, 1 death; Sheffield, 10 cases; South Shields, 14 cases.

India: Bombay, April 5-19, 34 deaths; Calcutta, April 3-10, 4 deaths; Karachi, April 10-17, 11 cases, 3 deaths.

Italy: Catania, April 8-May 5, 2 cases, 1 death.

Japan: Kobe, April 2-16, 3 cases; Nagasaki, April 10-20, 249 cases, 43 deaths.

Java: Batavia, March 26 April 9, 20 cases, 2 deaths.

Mexico: City of Mexico, March 27-April 3, 4 cases, 9 deaths; *April 16-May 8, 14 cases, 2 deaths; April 23-30, Tampico, 1 death; Vera Cruz, 1 case; Torreon, April 24-May 7, 27 cases, 15 deaths.

Netherlands: Rotterdam, April 23-May 7, 9 cases, 1 death

Russia: Moscow, April 8-23, 9 cases, 1 death; Odessa, April 23-30, 1 case; St. Petersburg, April 16-23, 7 cases, 4 deaths.

Spain: Barcelona, April 1-30, 9 deaths.

Turkey: Beirut, April 21-28, present.

YELLOW FEVER.

Ecuador: Guayaquil, April 16-23, 6 deaths.

Mexico: May 11, Talleres, 1 case; Tehuantepec, 1 case.

CHOLERA.

India: Madras, Apri 9-15, 1 death.

Turkey: Basra, April 1-10, 37 cases, 28 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, April 2-9, 3 cases, 2 deaths

PLAGUE—FOREIGN.

Africa: Cape Colony, April 8-16, 1 case, 1 death.

Egypt: April 8-16, 59 cases, 36 deaths: Port Said, 1 case, 1 death.

India: Bombay, April 12-19, 633 deaths; Karachi, April 10-17, 365 cases, 285 deaths; Madras, April 9-15, 1 death.

Formosa: March 31-April 9, 229 cases, 167 deaths.

New Zealand: Auckland, April 29, 2 cases, 1 death.

Peru: Callao, April 10-24, 2 cases, 2 deaths; Lima, April 16-23, 9 cases, 11 deaths.

Medical Organization.

Indiana.

INDIANA STATE MEDICAL ASSOCIATION.—This association met in Indianapolis, May 19 and 20, 1904, with an attendance of more than 500. The secretary reported a paid membership of 1,947, with probability that this would be increased to nearly 2,100 before the Transactions go to press. Eighty-four charters have been issued to county societies, making a gain of 13 organizations this year. The meeting was very profitable and interesting. "Medical Education" and "Tuberculosis" were the subjects that called forth the most animated discussions. Resolutions were adopted favoring a state hospital for tuberculosis. West Baden was chosen as the next place of meeting, and the following officers were elected: President, Dr. George T. McCoy, Columbus; vice-presidents, Drs. Homer J. Hall, Franklin; Claude T. Hendershot, Cannelton, and David J. Loring, Valparaiso; secretary, Dr. Frederick C. Heath, Indianapolis; treasurer, Dr. Albert E. Bulson, Jr., Ft. Wayne; and councilors, First District, Dr. William R. Davidson, Evansville; Second, Dr. George Knapp, Vincennes; Third, Dr. Harry C. Sharpe, Jeffersonville; Fourth, Dr. William H. Stemm, North Vernon; Fifth, Dr. Myron A. Boor, Terre Haute; Sixth, Dr. David W. Stevenson, Richmond; Seventh, Dr. William N. Wishard, Indianapolis;

---

*Report April 3-10, returned for correction. Report from April 10-17 will be found in Health Reports sent May 7.

Eighth, Dr. General W. H. Kemper, Muncie; Ninth, Dr. Paul J. Barcus, Crawfordsville; Tenth, Dr. Edward G. Blinks, Michigan City; Eleventh, Dr. Robert Hessler, Logansport; Twelfth, Dr. Albert E. Bulson, Jr., Fort Wayne, and Thirteenth, Dr. Charles A. Daugherty, South Bend.

West Virginia.

West Virginia State Medical Association.—The thirty-seventh annual meeting was held at Fairmont, May 10-12, the register showing 119 members present, a satisfactory attendance considering that this was the first meeting to be conducted on the new plan of organization. The secretary's report showed a steady progress in organization. The prospects for a complete organization of the profession of the state in the near future are very good. The following officers were elected: President, Dr. Thomas M. Hood, Clarksburg; vice-presidents, Drs. William C. Jamison, Fairmont, Edgar H. Parsons, Piedmont, and Arthur A. Shawkey, Charleston; secretary, Dr. William W. Golden, Elkins; treasurer, Dr. Vincent T. Churchman, Charleston; councilors: first district, Dr. Rezin W. Hall, Moundsville; second district, Dr. Martin F. Wright, Burlington; third district, Dr. Timothy L. Barber, Charleston; fourth district, Dr. William S. Ke [illegible] fifth district, Dr. Corydon R. Enslow, [illegible] was elected for the next meeting place.

Society Proceedings.

COMING MEETINGS.

American Medical Association, Atlantic City, N. J., June 7-10

American Medico-Psychological Assn., St. Louis, May 30-June 3.
Amer. Laryn., Rhin., and Otol. Society, Chicago, May 30-June 2.
South Dakota State Medical Association, Redfield, June 1-2.
Maine Medical Association, Portland, June 1-3.
International Assn. of Railway Surgeons, Chicago, June 1-3.
Minnesota State Medical Society, Minneapolis, June 2-3.
American Therapeutic Society, New York City, June 2-4.
American Dermatological Association, Niagara Falls, June 2-4.
Rhode Island Medical Society, Providence, June 3.
Conf. of State and Prov. Bds. of Health of N. A., Wash., June 3-4
Indian Territory Medical Association, Holdenville, June 3-5.
American Academy of Medicine, Atlantic City, June 4-6.
Medical Society of New Jersey, Atlantic City, June 4-7.
Nat. Conf. State Med. Exam. and Lic. Bds., Atlantic City, June 6.
American Medical Editors' Association, Atlantic City, June 6.
American Assn. Life Ins. Exam. Surgs, Atlantic City, June 6.
American Gastro-Enterological Association, Atlantic City, June 6.
Nat. Assn. of U. S. Pen. Exam. Surgs., Atlantic City, June 6-7.
Association of American Medical Colleges, Atlantic City, June 6.
Massachusetts Medical Society, Boston, June 7-8.
American Protologic Society, Atlantic City, June 8-9.
American Orthopedic Association, Atlantic City, June 8-10.
American Urological Association, Atlantic City, June 10-11.
Medical Society of Delaware, Lewes, June 14.
Wisconsin State Medical Society, Milwaukee, June 22.

SECOND LATIN-AMERICAN CONGRESS.

Held at Buenos Ayres, April 3-10, 1904

The President, Prof. E. R. Coni, in the Chair.

The first medical congress to unite all the countries of South America, Mexico and the West Indies was held in 1901 in Chili, in the midst of troublous political rumblings. The sky has since cleared, and the congress held last month at Buenos Ayres was under the most favorable auspices. The membership was 1,068, including 477 physicians from countries outside of Argentine, many of them delegates from scientific societies. Nearly 260 communications were presented, the larger number being on subjects relating to hygiene and bacteriology. About 250 exhibitors took part in the "international exposition of hygiene," which included exhibits showing the details and progress of the national antituberculosis leagues and the Red Cross.

Etiology of Yellow Fever.

Dr. José Penna is professor of clinical epidemiology at Buenos Ayres, and has long had charge of the isolation hospital. His address on "Yellow Fever" reviewed all the testimony to date presented, including some unpublished work, and unhesitatingly announced that Sanarelli's statements in regard to the icteroid bacillus had been confirmed by time and experience, with complete substantiation of all his claims. The Havana experiences are qualified as undemonstrative and inadequate. The Havana commission has not yet offered proof that the experimental disease induced by the bites of infected mosquitoes is true yellow fever. The circumstances of their tests are not conclusive as to the possibility of contagion from infected articles. The same criticism applies also to the work of the French yellow fever commission. Prophylaxis of yellow fever should be based as heretofore on disinfection and isolation, but international prophylaxis should suppress every measure that interrupts free circulation and commerce. His final conclusion is to the effect that if the mosquito should prove after all to be the intermediate host of the true yellow-fever germ, our efforts should be devoted not to exterminate it, but to cherish and cultivate it as the providential agent for immunization, as we preserve and utilize cowpox material. The fact that Sanarelli's serum treatment of yellow fever has not met with great success may be due to the small doses used. Penna was skeptical at first himself, but after becoming more familiar with serum treatment in general, and witnessing its success in diphtheria and in 160 cases of bubonic plague, in tetanus, anthrax and erysipelas, he became convinced that the failures were due to the ridiculously small tentative dosage. Similar doses in the above affections would be equally ineffectual. All the arguments presented against Sanarelli's assertions are superficial and theoretical. None of those who impugn the results of his research has repeated his experiences; none of them has inoculated the icteroid bacillus or its toxins in any of the human beings who have volunteered their services for experimentation. None of them has inoculated animals under the same conditions as Sanarelli. Sternberg, Agramonte, Reed and Carroll are mute in this respect. Why did they not experiment with the toxin of the icteroid bacillus? Penna thinks that research in this line is now indicated. Bandi of Sao Paulo and others of large clinical experience also regard the mosquito theory as far from being conclusively demonstrated as yet. Penna's address is given in full in the *Semana Medica* of April 7. Penna's views were opposed by the other speakers. See page 1430.

ILLINOIS STATE MEDICAL SOCIETY.

Fifty-fourth Annual Meeting, held at Bloomington, May 17-19, 1904.

Under the Presidency of Dr. Carl E. Black, Jacksonville.

The New Officers.

The following officers were elected for the ensuing year: President, Dr. William E. Quine, Chicago; vice-presidents, Drs. H. C. Mitchell, Carbondale, and J. F. Percy, Galesburg; secretary, Dr. E. W. Weis, Ottawa; treasurer, Dr. Everett J. Brown, Decatur. Rock Island was selected as the place for holding the next annual meeting.

The scientific work was divided into two sections, medical and surgical. We present herewith brief abstracts of many of the papers:

The Contagiousness of Typhoid Fever and the Vitality of the Typhoid Germ.

Dr. F. D. Rathburn, Galesburg, pointed out the vitality of the typhoid bacillus, both inside and outside the living body, and their power to generate in soils and other favorable media. He emphasized the importance of disposing of the excreta to prevent the spread of the disease. The germ has been shown to remain active for a considerable length of time after the fever in (1) post-typhoid abscess; (2) the urine; (3) contents of lung cavities; (4) gall bladder, and (5) evacuations from the bowels. The proper disposition of the excreta is the only method of prevention. Cremation he considered the best method. When cremation is not practicable, he suggests that the excreta be deposited in heavily glazed earthenware receptacles, treated with germicides, and buried deeply at a distance from the water supply.

Mental Disorders of Neurasthenia.

Dr. Frank P. Norbury, Jacksonville, said that the mental symptoms of this disease are of importance in every case. They vary from slight mental incapacity to a pronounced state of insanity. The principal symptoms mentioned are introspection, imperative conceptions, morbid fears, irritability (marked by absence of symmetry), nagging, fault-finding, and excessive emotional outbreaks. The treatment consists of isolation, systematized rest, with adjuvants indicated in each case; also treatment of associated physical factors.

The Treatment of Appendicitis from a Pathologic Standpoint.

Dr. E. C. Franing, Galesburg, pointed out the differences of opinion on the treatment from a clinical standpoint. He spoke of the treatment of the various forms of the disease, paying particular attention to the Ochsner and the operative treatments.

The Relation of Medicine to Surgery.

Dr. James E. Coleman, Canton, thinks that whereas in former days the surgeon was first and foremost a fine physician, now surgeons neglect medicine. He discussed some avoidable surgical affections of the ovaries.

Leukemia; with Special Consideration of Its X-ray Treatment.

Dr. Everett J. Brown, Decatur, gave the history of a case of splenomedullary leukemia, with a greatly enlarged spleen, in which the use of the x-ray caused the disappearance of all symptoms. He considered the cases in literature so treated, and presented a summary.

Polyneuritis.

Dr. L. Harrison Mettler, Chicago, stated that multiple neuritis is a much-abused term. The general conception of the disease and the text-book descriptions of it are far too narrow. It is a disease more or less of the entire nervous apparatus. He spoke of the central and peripheral types of the disease; of the relative significance of the interstitial and parenchymatous disease processes. He spoke of the relative importance of the particular etiologic influences, and pointed out the clinical indications of the extensive nature of the disease. Pathologic proofs were advanced. He referred to the differential diagnosis of types of the disease requiring variable treatment.

The Pneumonia Problem.

Dr. Arnold C. Klebs, Chicago, spoke of investigations into statistical data regarding this disease, and its increase in the United States and abroad. He made a comparison of nontuberculous respiratory diseases and tuberculosis, both clinical and statistical. He pointed out the dangers of pneumonia to the individual and to the community, and how they can be met.

Dr. Charles J. Whalen, Chicago, gave a comparison of mortalities from pneumonia and tuberculosis. He pointed out the possibility of making headway against the disease from a prophylactic standpoint. Expectant treatment is the most satisfactory, and among other things he mentioned rest, ventilation, sponging, elimination, poultices and glycerin; also the value of antipyretics, serum therapy, venesection, arterial sedatives, oxygen, opium, creosote, normal salt solution, suprarenalin, stimulants, expectorants, etc.

Brain and Sinus Diseases Resulting from Purulent Otitis Media.

Dr. A. H. Andrews, Chicago, said that the brain and sinus complications are more common than is generally supposed. He stated that pus in the mastoid escapes in one of six directions. The intracranial complications may be general meningitis, extradural abscess, cerebral abscess, cerebellar abscess and sinus disease. He expatiated at length on the symptoms and treatment, followed by a report of cases.

Classifications of Joint Affections.

Dr. August F. Lemke, Chicago, pointed out the distinguishing features between the joint diseases known as the rheumatic arthritides and the group known as arthritis deformans. He discussed the treatment of some of the more important joint lesions.

Middle Ear Suppuration.

Dr. Norval H. Pierce, Chicago, reported additional cases of sigmoid sinus thrombosis from middle ear suppuration.

Dr. Willis O. Nance, Chicago, stated that acute otitis media of infancy and early childhood was frequently an unrecognized process. The recent investigations of Ponfick, Barth and others demonstrate that a large proportion of infants and young children at some time suffer from middle ear inflammation. The dangers from non-recognition were pointed out; also the close relationship between acute purulent otitis media and acute infectious processes other than diphtheria and scarlet fever, namely, gastrointestinal disturbances and bronchopneumonia. He mentioned the structural variations between the infant and adult middle ear, and the diverse characteristic manifestations of inflammation in each. Considerable attention was paid to the diagnosis and treatment of acute infantile otitis media.

Corneal Ulcers.

Dr. William H. Wilder, Chicago, in speaking of infectious ulcers of the cornea, said that the underlying cause is to be sought in impaired vitality of the tissues from a general or local depraved nutrition. The active cause is usually some trauma, which is supplemented by a virulent infection. The source of the infection is frequently in the tear sac. He emphasized the importance of prompt recognition and active treatment. Cauterization of the ulcer plays a prominent rôle in the treatment, as do also constitutional measures.

Cholecystitis.

Dr. M. L. Harris, Chicago, said that microbes may retain vitality for a very long time in the gall bladder. Cholecystitis is often mistaken for other conditions. He referred to the advantages and necessity of drainage of the gall tract in cholecystitis, and the length of time drainage should be continued.

Kidney Surgery.

Dr. Arthur Dean Bevan, Chicago, gave a brief historical review of this subject, and mentioned the pathologic conditions warranting surgical interference. He likewise mentioned the means of diagnosis, and in discussing the surgical treatment, referred to nephrorrhaphy, nephrotomy, nephrolithotomy, nephrectomy, and plastics on the kidneys and ureters. Attention was directed to the prognosis after kidney operations.

Subcutaneous Injuries of the Abdominal Wall and Viscera.

Dr. D. N. Eisendrath, Chicago, said that many lives might be saved by prompt recognition of serious injuries of the abdominal viscera in which there is only slight injury of the skin. He alluded to the greater amount of protection of certain organs; discussed the manner in which injuries occur, and the mode of examination for the purpose of making a diagnosis. He reported a number of cases, analyzed statistics and drew deductions therefrom.

(To be continued.)

ASSOCIATION OF AMERICAN PHYSICIANS.

Nineteenth Annual Meeting, held at Washington, D. C., May 10 and 11, 1904.

The President, Dr. W. T. Councilman, in the Chair.

(Continued from page 1378.)

Abdominal Pain from Unsuspected Irritation of the Internal Inguinal Ring.

Dr. Charles G. Stockton, Buffalo, read a paper on the first day, afternoon. He reported 12 cases of abdominal pain which was due to irritation at the internal abdominal ring. These were not cases of hernia as commonly understood, but of very slight protrusion at this ring, sufficient to produce quite severe pain, sometimes in paroxysmal attacks and sometimes constant in character. The attacks are to be differentiated from appendicitis and may be relieved by the application of a truss.

DISCUSSION.

Dr. Charles Carey, Buffalo, referred to a case in which the merest trace of a hernial sac at the internal abdominal ring produced pain of serious character. The condition was confirmed by an operation.

Dr. George L. Peabody, New York City, referred to a similar case in which the symptoms were relieved by the application of a truss.

Dr. Charles S. Bond, Richmond, Ind., referred to a case of like character in which a truss relieved the pain.

Dr. George Dock, Ann Arbor, said that abdominal pain is often felt at a point far removed from the seat of the disease. He spoke of a case in which there was swelling in the right inguinal region, produced by a small hernia, in which the attacks of pain had been like those of gallstone colic. After an operation for the relief of the hernia, during which the gallbladder region was examined and found healthy, the attacks of pain ceased.

Dr. Stockton emphasized the point that the cases included in his report were caused by mere bulging at the internal ring and not by the formation of a true hernial sac. All the patients were relieved by the application of suitable trusses.

The Mechanism of Exophthalmos.

Drs. W. G. MacCallum and W. B. Cornell, Baltimore, described experiments designed to discover the cause of exophthalmos and an instrument for recording in a graphic manner the degree of protrusion of the eyeball after various manipulations. They find that both respiration and the pulsation of the heart produce some change in the degree of protrusion of the eyeball when a graphic record is made. If the internal jugular vein be ligated there is slight protrusion of the eye, but a more marked protrusion is produced if the external jugular be ligated. Ligation of the carotid arteries lessens this protrusion slightly. The protrusion thus produced is relieved by the establishment of the collateral venous circulation, although the development of edema in the orbital tissues tends to maintain the condition to some degree. In the dog stimulation of the cervical sympathetic nerve produces protrusion of the eyeball, dilation of the pupil and widening of the palpebral fissure, independent of any change in the blood vessels. The actual cause of the protrusion is the peristaltic contraction of a cone of tissue containing smooth muscle fibers which surrounds the eyeball. In the human subject stimulation of the cervical sympathetic does not cause exophthalmos, so that no parallel can be drawn between these experiments and Graves' disease.

Diabetes Insipidus.

Dr. Thomas B. Futcher, Baltimore, reported a study of 9 cases of diabetes insipidus from the Johns Hopkins Hospital, showing the rarity of the condition. He classifies the disease into a primary or essential group and a secondary or symptomatic group. The disease is usually found between the ages of 20 and 30. Many of the patients presented a history of gout, nephritis or tuberculosis in their ancestors; heredity is a marked factor in some cases. The disease is more prevalent among males than among females. Some lesion of the brain is the most common pathologic finding. Syphilis was an important etiologic factor in 4 out of the 9 cases; the most common form of syphilitic lesion was a basilar gummatous meningitis.

DISCUSSION.

Dr. Baumgarten, St. Louis, referred to a case of diabetes insipidus which developed into true diabetes mellitus.

Dr. W H. Thomson, New York City, referred to two cases of diabetes insipidus, neither of which showed signs of syphilis.

Dr. James Tyson, Philadelphia, said that he had seen 6 or 7 cases in his experience. Potassium iodid is the most satisfactory drug in the treatment of the condition. The father of one of his patients was thought to have been syphilitic.

Dr. George Dock, Ann Arbor, said that some cases of this condition seem to be hopeless. He recalled one case that followed an attack of hemiplegia in which mercury and the iodids had no effect.

Dr. Abraham Jacobi, New York City, said that the condition is common in infancy and childhood. The condition develops after anemia, chorea, whooping cough, falls on the occiput and some of them seem to be connected with tumors. Atropin gave good results in the cases he has seen in children.

Dr. Futcher said that he had seen one case that followed typhoid fever. He does not wish to be understood as believing that syphilis is the only cause of the condition.

A Case of Prolonged Male Hysteria with Autopsy.

Drs. S. Weir Mitchell and William G. Spiller, Philadelphia, read this paper. The patient was a man who had had uncomplicated hysteria for 30 years. He died suddenly and a postmortem examination gave only negative results.

Dr. Morton Prince, Boston, said that, according to the modern view, hysteria depends on the dissociation of cerebral centers and on the automatic action of the dissociated centers. Experiment has shown that in hysterical anesthesia there is no anesthesia, but that the sensory centers fail to act because they are not associated.

Dr. Horatio C. Wood, Philadelphia, said that the periodic movements of the hysterical patient belong to the category of involuntary movement and since there is no sense of fatigue no record is left on the brain cells in the area governing the voluntary movements of the parts.

Some Unusual Forms of Acute Myelitis.

Dr. B. Sachs, New York City, referred to other forms of acute myelitis than those due to syphilis, trauma and the infectious diseases. The condition appears to be a general degeneration of the spinal cord from interference with its blood supply. He reported the case of a man, aged 65 years, who had the symptoms of transverse myelitis. At autopsy a simple degeneration of the spinal cord without hemorrhage was found, the blood vessels being arteriosclerotic. In the case of a girl, aged 15 years, who suddenly became unconscious and developed paraplegia with involuntary micturition and defecation, a diagnosis of acute transverse myelitis was made. The patient had high fever and developed multiple abscesses, from the pus of which streptococci were obtained. In spite of two attacks of erysipelas the patient did not die and is now a chronic paraplegic. He likens the cases to certain cases of encephalitis due to circulatory disturbance without hemorrhage.

Infectious Neuritis.

Dr. James J. Putnam, Boston, reported cases showing the same infectious agent may act on the nervous system in different ways at different times. The clinical and the pathologic pictures are often confused.

DISCUSSION.

Dr. William H. Welch, Baltimore, said that the spinal cord is very sensitive to partial anemia, a primary ischemic necrosis resulting, which is not, strictly speaking, a myelitis. It is possible by compressing the aorta of a rabbit for an hour to produce a transverse myelitis. He regards the case reported by Sachs as of this type. It is often difficult to demonstrate the source of the anemia.

Dr. Sachs said, in answer to a question by Dr. William H. Park, New York City, that he did not do a lumbar puncture in the girl because he considered it important not to withdraw any of the septic material from the cord into the subarachnoid space.

Cerebrospinal Fever.

Dr. Henry Koplik, New York City, read a paper entitled "The Clinical Features, Prognosis and Treatment of Cerebrospinal Meningitis in Infants and Children." He studied 49 cases of cerebrospinal meningitis, which he divides into three classes: (1) a malignant type, characterized by sudden illness with the development of an erythematous rash followed by hemorrhages; (2) a chronic type, like the adult cases, and (3) a group of atypical cases. The Babinski reflex was absent in the majority of cases, but was present in about 5 per cent. In tuberculous meningitis, on the other hand, this reflex is present in 77 per cent. of cases. It is, therefore, an adjunct to the differentiation of the diseases. Kernig's sign is usually positive in cerebrospinal meningitis. It is of little value, however, in children below 2 years old. The temperature in young children is intermittent, so that the chronic cases are sometimes taken for malaria. There is usually no change in the fundus of the eye in cases of cerebrospinal meningitis; in only one out of 21 cases was there a descending neuritis; just the reverse of the condition seen in tuberculous meningitis. There is usually a leucocytosis, the highest being 24,000. The prognosis does not seem to be affected by the degree of the leucocytosis.

When a lumbar puncture obtained fluid, the *Diplococcus intracellularis* was usually found. In some of the cases of the type described by Still no diplococci were found, but there is no support of the view that the cases of the Still type are tuberculous. Lumbar puncture is not curative; it does not prevent relapses and it does not prevent the development of severe symptoms. It is indicated in infants and young children and is curative in those cases in which the development of hydrocephalus is to be expected. Injection of fluid into the subarachnoid space was found unsatisfactory therapeutically.

Esophageal Stricture.

Drs. James Tyson, Edward Martin and Joseph Evans read a paper entitled "Two Cases of Spasmodic Stricture of the Esophagus with Sacculation Treated by Dilation and Later by Gastrostomy." The first patient was a man, aged 33 years, who had had dysphagia since he was 12 years old. He came of a tuberculous and neurotic family and was himself of a neurotic temperament and an irregular liver. He was able to overcome the spasm at the cardiac end of the stomach after eating by drinking large quantities of fluid and swallowing forcibly many times. By potassium iodid and salol it was shown that there was no passage of food into the stomach when it was not forced in in the way just described. When food was forced into the stomach the motor power of the organ and the absorption were found normal. The patient had a right floating kidney, gastroptosis and a slow pulse. The second patient was a woman, aged 33 years, who first felt a choking sensation behind the sternum two years ago. The attacks of choking increased so that only fluids could be swallowed, solid food being regurgitated. She became weak, emaciated and nervous. Martin first tried to dilate and paralyze the esophageal opening into the stomach by having the patient swallow an instrument, devised by himself, constructed like an urethral dilator, which was opened and withdrawn. This gave some improvement for a time, but soon the condition returned as bad as before. A gastrostomy was then done and the patient is now being fed through the wound.

Idiopathic Dilation of the Esophagus; Cardiospasm.

Dr. Bertram W. Sippy, Chicago, reported the case of a woman, aged 37, who had complained of dysphagia and vomiting for five years. She was thought to be hysterical. She lost weight and, after a diagnosis of pyloric obstruction, gastroenterostomy was performed. Following the operation there was less pain, but the patient did not gain in weight and soon the old symptoms returned. A gastrostomy was done, but the patient became weaker and died in a toxic condition. The specimen was exhibited. The esophagus held 500 c.c.; there was no anatomic stricture; the lower inch of the tube was not dilated; the wall of the dilated portion was hypertrophied. There was no pyloric obstruction.

DISCUSSION.

Dr. Francis P. Kinnicutt, New York City, exhibited a specimen from a patient who died of the same condition. The esophagus held 1,800 c.c. There was no anatomic cause for the obstruction. The stomach was dilated and dislocated; the pylorus was moderately stenosed. The patient had suffered from dysphagia and regurgitation for 20 years. He died of inanition.

Dr. E. G. Janeway, New York City, showed the skiagraph from a patient who had had dysphagia with hemoptysis for 20 years. Some food was regurgitated with the blood, which led to the exclusion of tuberculosis and the discovery of the dilated esophagus, which held from 500 to 800 c.c. A test meal withdrawn from the esophagus showed a moderate amount of lactic acid acidity. A test meal withdrawn from the stomach showed the presence of free hydrochloric acid and peptones. He also referred to the case of a girl who, since infancy, has been able to retain 10 ounces of fluid in her esophagus. By percussion in this case he was able to get dullness along the vertebral column when the esophagus is distended with food and tympany when it is empty. He said that Dr. S. J. Meltzer, New York City, was the first to describe these cases and to explain the mechanism of their production in 1888.

(To be continued.)

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment; such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Cold Abscess.

The treatment of cold abscesses, according to Prof. Lannelongue in *Med. Press*, should be at first directed toward the general condition of the patient. Sea air, nourishing food and cod-liver oil are of service. Locally the best treatment is tapping, followed by an antiseptic injection. Different liquids have been employed by the author, such as tincture of iodin, zinc chlorid, silver chlorid, camphorated naphthol and iodoform in ether. The last two are preferably used. Before tapping the abscess the parts should be washed with soap and water and finally with alcohol. The point at which the trocar is inserted is of importance; it should be selected a little beyond the limits of the abscess so that before penetrating into the cavity the instrument should pass through healthy tissue. This point should be situated at the highest part of the abscess, and not in the lowest, as in ordinary inflammatory suppurations. In observing these precautions a secondary fistula may be avoided. After anesthetizing the point chosen with chlorid of ethyl or a solution of cocain (1-100) the trocar is inserted slowly until the cavity is reached, when it is withdrawn, leaving the canula. After the cavity has been drained the antiseptic fluid should be injected. It must be remembered, if camphor naphthol is used, that it is not an inoffensive preparation, and accidents may happen. The dose should not exceed half a dram (1.00).

If iodoform in ether is used, one dram (4.00) may be injected slowly to avoid pain, and after the ether has evaporated the powdered iodoform remains in the cavity, when a small piece of sterilized gauze may be inserted and held in position by collodion.

Vesicular Eruptions.

Bazin, in an abstract in *N. Y. and Phila. Med. Jour.*, recommends the following combinations containing mercury subsulphate in the treatment of vesicular eruptions:

℞.	Hydrarg. subsulph.	ʒss	2
	Olei amygdalæ dulcis	ʒiiss	10
	Adipis	℥ii	60

M. Ft. unguentum. Sig.: To be applied locally; or:

℞.	Hydrarg. subsulph. (Turpeth mineral)	gr. xv	1
	Glycerini		
	Olei amygdalæ dulcis, āā	ʒi	4
	Adipis	℥iss	45

M. Ft. unguentum. Sig.: Apply locally.

Scabies in Children.

The following combinations are recommended by *Jour. des Pract.* in the treatment of scabies in children:

℞.	Sulphuris precip.	ʒi	4
	Potass. carb.	ʒss	2
	Olei amygdalæ		
	Aq. destil., āā	ʒss	2
	Adipis	ʒvi	24

M. Ft. unguentum. Sig.: Apply locally.

To soothe the skin previous to applying the foregoing ointment the following is of service applied locally:

℞.	Zinci oxidi		
	Amyli, āā	ʒv	20
	Liq. petrolati	ʒx	40

M. Sig.: Apply morning and evening.

Tonsillitis.

J. Scott Brown, in *Med. News*, considers a large percentage of the cases of chronic tonsillitis to be of rheumatic origin.

He treats locally and internally with the tincture of the chlorid of iron and locally also with formalin and iodin sprays, keeping the nasal passages cleansed out with Dobell's solution employed in the form of a douche. In acute cases he administers calomel in broken doses until the desired effect is produced, after which a tablet containing the following ingredients are administered:

℞. Tinct. aconiti rad.	gtt. 1/5	012
Tinct. bryoniæ		
Tinct. belladonnæ, āā	gtt. 1/10	006
Hydrarg. iodidi rubri	gr. 1/100	0006

M. Ft. tabla No. i. Sig.: One such tablet every hour to an adult until eight are given.

Alternating with the foregoing quinin is given in one grain doses for eight doses.

As a spray the following is recommended by the author:

℞. Formalin (40 per cent.)	m. iii	20
Glycerini	ʒii	8
Aquæ q. s. ad	℥i	30

M. Sig.: As a spray three times a day; and:

℞. Formalin	gtt. iii	20
Glycerini	ʒvi	24

M. et add:

Tinct. iodi	gtt. xx	1|30

M. et add:

Alcoholis	ʒiv	15
Aquæ q. s. ad	℥iv	120

M. Sig.: To be used as a spray following immediately the first spray.

As a gargle a solution of alcohol in water in the desired proportions may be employed three or four times daily, increasing or decreasing the amount of alcohol as is indicated in the individual case.

The Care of Children's Teeth.

As a mouth wash to prevent the decay of teeth the following combination is recommended by *Western Druggist:*

℞. Acidi tannici	ʒii	8
Tinct. iodi	ʒi	4
Pot. iodidi	gr. xv	1
Tinct. myrrhæ	gtt. lxxx	5
Aquæ rosæ q. s. ad	℥vi	180

M. Sig.: Rinse the mouth thoroughly with this solution two or three times daily to prevent the decomposition of food particles and consequent caries of the teeth.

In cases where it is thought desirable to attempt to counteract a tendency toward loosening of the teeth the following mouth wash is recommended:

℞. Acidi benzoici	gr. x	65
Thymol	gr. i	06
Acidi salicylici	gr. v	30
Tinct. eucalyptus	gtt. xlv	3
Aquæ q. s.	℥vi	180

M. Sig.: One teaspoonful in water to rinse the mouth every two or three hours.

The teeth should be cleansed at least once daily after the last meal, using at the time a little tooth powder or a little soap or precipitated chalk, after which the mouth should be thoroughly rinsed.

To Purify the Sick Room.

The following antiseptic combination is recommended as a vapor in the sick room:

℞. Eucalyptol	ʒiiss	10
Olei thymi		
Olei limonis		
Olei lavendulæ flor., āā	ʒi	4
Alcoholis	℥iv	120

M. Sig.: One teaspoonful to be floated on a pint of boiling water and allowed to evaporate.

Hepatic Colic.

According to an abstract in *Amer. Jour. of Med. Sciences*, the indications to be met in the treatment of hepatic colic is to relieve the pain; to facilitate as much as possible the passage of the calculus; to prevent complications. The pain may be relieved by the hypodermic use of morphin and atropin, guarding the use of the latter preparation when there is a tendency to collapse. To patients who do not bear morphin well, chloroform *may* be given to the obstetrical degree, or if there is no vomiting the following combination:

℞. Chloralis	ʒss	2
Syr. menth. pip.	℥i	30
Aq. chloroformi	℥iii	90

M. Sig.: Two dessertspoonfuls every fifteen minutes until relieved. When the stomach is too irritable the chloral may be given per rectum as follows:

℞. Chloralis	ʒss-i	2.-4
Aq. bullientis	ʒiiss	10

M. et add:

Ovi vitelli (one)		
Vini opii	m. xv	1
Lactis	℥vi	180

M. Sig.: To be used as an enema.

Ether and turpentine on the one hand and olive oil and glycerin on the other, are the usual remedies employed to facilitate the passage of the stone. The latter are more frequently employed. To overcome the disagreeable taste of the olive oil, it may be stirred up with a little ale or to it may be added a little menthol or a few drops of the essence of bitter almonds or anise. The quantity of the oil should range from four to eight ounces. Glycerin is more pleasant to take, but less effective. Hot water bags applied externally are of great value in relieving the spasm of the duct.

Disturbance in the circulation and heart failure is the chief complication of hepatic colic. To combat it, it is recommended that sparteín be substituted for the atropin. Chloral should not be given where collapse is threatened and in case such should occur hypodermic injections of camphor are recommended. *To prevent accidents to the biliary passages the use* of purgatives should be avoided and all food suspended until the pain has ceased for several hours. Surgical interference, of course, is imperative if rupture of the bile passages occurs.

Hyperchlorhydria.

The mechanical difficulty some patients experience in taking magnesia, bismuth or charcoal in the powder form is appreciated by R. M. Harbin of Rome, Ga., who writes to The Journal and recommends the following serviceable mixture in the treatment of hyperchlorhydria:

℞. Strontii bromidi	ʒiss	6
Carbo ligni	ʒi	4
Bismuthi subnit.	ʒiv	15
Lactis magnesiæ	℥iii	90
Aq. menth. pip. q. s. ad	℥vi	180

M. Sig: Shake and take one tablespoonful one hour after meals.

If an antiferment is indicated the mild chlorid of mercury should be given in divided doses.

Medicolegal.

When Is the Question as to Injuries One for Experts Only?—The Supreme Court of Oklahoma holds, in Willet vs. Johnson, a personal-injury case, that, where the injuries are of such a character as to require skilled and professional men to determine the cause and extent thereof, the question is one of science, and must necessarily be determined by the testimony of skilled professional persons, and can not be determined from the testimony of unskilled witnesses having no scientific knowledge of such injuries.

The Weighing of Dying Declarations.—The Court of Appeals of Kentucky says, in the homicide case of Commonwealth vs. Lawson, that it fully recognizes that the question of the admission of dying declarations is primarily for the determination of the court, but this only relates to the question of the admissibility of the evidence; in other words, whether or not the condition of the decedent's mind, with reference to his death, is such as that the awfulness of his situation will supply the sanctity of an oath. After the testimony is in, the weight that is to be given it, either in part or in whole, is for the determination of the jury. The defense may impeach the credibility of the declarant, may show that he made a different statement to that contained in the declaration, or that the declaration is untrue in fact; but, after all, the question as to whether or not the declarant made the declaration as testified to, or whether it is true in whole or in part, or whether he made a declaration at all, are issues for the determination of the jury, and not for the court.

Scope of Prosecution for Unlawfully Practicing Medicine.—In Payne vs. State, where it was charged, among other things, that the former did unlawfully practice medicine without a license, the Supreme Court of Tennessee says that, while it is true that in certain misdemeanor cases testimony may be introduced tending to show numerous infractions of the law, falling within the period of limitation, although there be only one count or charge in the indictment or presentment, and true that in such cases the court, on application of the defendant, will compel the state to elect the particular offense or instance on which it will ask a conviction at the hands of the jury, yet the court does not think the rule applies to a case such as this one. Here the defendant (Payne) was indicted for practicing medicine without a license. The term "practicing," in respect of the subject in connection with which it is used, indicates the pursuit of a business. The fact that the defendant was pursuing such business may be proven in some cases, no doubt, by a single act, where that act is clear and definite, and is so supported by other circumstances as to indicate that he was indeed pursuing the business in question; but in all cases it is far more satisfactory that a series of acts of a similar nature be proven, all tending to show that the defendant was engaged in the forbidden occupation, to the end that the jury may be enabled to determine from the defendant's course of conduct whether he is guilty of the charge. In other words, under such a charge, each several instance of advising patients, prescribing for them, or administering medicine to them is not necessarily an offense, but these facts all taken together, when considered in connection with the further fact that the defendant had no license to practice, go to prove the charge of practicing without license. It is no more difficult for the jury to examine and draw conclusions from such a series of facts than from any other series tending to support a general proposition, nor is it more difficult for the defendant and his counsel to prepare the defense and present it to the jury. Nor can any inconvenience or hardship arise in pleading former acquittal or former conviction, as the case may be, in event there should be a subsequent prosecution. Necessarily, from the very nature of the case, an indictment for unlawfully practicing medicine would cover all special instances occurring prior to the indictment or presentment in the particular venue or county, and going to sustain the main charge; hence a former acquittal or conviction could be pleaded in bar of any subsequent prosecution based on such prior acts.

Proof of Claim—Physician's Visiting List as Evidence.—The Nebraska case of Cather vs. Damerell, which is "not to be officially reported," but is reported in 96 Northwestern Reporter, 35, was brought by the latter party, a practicing physician and surgeon, against an administrator to recover a balance due on an account for professional services rendered the decedent and his wife. The first contention of the administrator was that the claimant neither alleged nor proved that he had complied with the provisions of the statute regulating the practice of medicine. But the Supreme Court Commissioners of Nebraska say that he alleged that at the time the services were rendered he was a regular, practicing physician, and this allegation was fully sustained by the evidence. He could not have been practicing lawfully without a compliance with the provisions of the act in question, and the law raised no presumption that he practiced unlawfully. The rule seems to be that when the question of license arises collaterally, in a civil action between a physician and one who employs him, his qualification under the statute will be presumed, and the burden is on him who denies such license. Lacy vs. Kossuth County, 106 Iowa, 16; Lyford vs. Martin (Minn.) 82 N. W. Rep. 479; City of Chicago vs. Wood, 24 Ill., App. 40. Another contention of the administrator was that the court erred in receiving a certain account book of the claimant in evidence. The books received in evidence were shown to be what is known as a "physician's visiting list." The pages are ruled in such a way as to leave a space at the top for the year, month and day of the week, and for special memoranda in separate columns. In the column headed with the year and month is the name of the patient. In this particular case the account was shown to have been kept by placing a dot for each visit, and a cross for each local application, opposite the patient's name, in the column headed the day of the week on which the services were rendered. The credits were entered in the column for special memoranda. One complaint in regard to the books was in regard to the arbitrary signs used to indicate the services rendered. This complaint, the commissioners say, was without merit. The law does not require an account to be kept in any particular language. A notched stick, pieces of board sawed out of a corncrib, and boards on which the measurement of lumber were kept, have all been held good books of original entry, and receivable in evidence. Rowland vs. Barton, 2 Har. (Del.) 288; Pallman vs. Smith, 135 Pa. 188. In the light of these cases, the system of bookkeeping adopted by the claimant in this case was by no means crude. As a matter of fact, it appeared to be a very convenient and simple one. But it was insisted that no sufficient foundation was laid for the admission of the books in evidence. The reception of books of account in evidence is regulated by section 346 of the Nebraska Code of Civil Procedure, which is as follows: "Books of account, containing charges by one party against the other, made in the ordinary course of business, are receivable in evidence only under the following circumstances, subject to all just exceptions as to their credibility: First, the books must show a continuous dealing with persons generally, or several items of charges at different times against the other party in the same book; second, it must be shown, by the party's oath or otherwise, that they are his books of original entries; third, it must be shown, in like manner, that the charges were made at or near the time of the transaction therein entered, unless satisfactory reasons appear for not making such proof; fourth, the charges must also be verified by the party or the clerk who made the entries to the effect that they believe them just and true, or a sufficient reason must be given why the verification is not made." The wife of the claimant was called as a witness to make the preliminary proof for the introduction of the books in evidence. She had been the wife of the claimant for nineteen years, and showed herself familiar with his business and bookkeeping, as well as a familiarity with his accounts. She testified that the books were his books of original entry. She also testified to the meaning to be given the arbitrary signs therein, in such a way as to make the book easily understood. The value of the services shown by the books was established by the evidence. The books, on their face, showed numerous items of charges at different times against the decedent. The evidence was not entirely satisfactory that the charges were made at or near the time of the transactions therein entered, and there was no evidence on the part of the claimant, who made the entries, that he believed them just and true But he was incompetent (ground not stated) as a witness to prove such facts, and that would be sufficient reason, within the meaning of the section quoted, for the failure to make such proof. Martin vs. Scott, 12 Neb. 42. It would seem that the claimant brought himself clearly within the statute prescribing the conditions on which books of account may be received in evidence, and that the court did not err in receiving such evidence. The Supreme Court of Nebraska proves the conclusions reached by the commissioners.

May 14.

1 *Carcinoma of the Esophagus. W. M. L. Coplin.
2 *Is the Epileptic Attack Explosive in Character? J. W. Wherry.

3 *A Contribution to the Physiologic Study of the Normoblasts. Julio F. Arteaga.
4 *The Puerpera: Her Care and Comfort During Convalescence, Particularly the Prevention of Visceral Prolapse. A. Ernest Gallant.
5 *Further Experiences with Intratracheal Medication. P. S. Donnellan.
6 The Correct Technic for Packing the Urethra, in Gonorrhea, Gleet and Stricture; Two New Instruments. S. T. Rucker.

1. **Carcinoma of the Esophagus.**—Coplin discusses the frequency and types of the condition and reviews the special points of its occurrence in the literature. He agrees with Pepper's statement that metastasis is less frequent than in carcinoma of the other organs, excluding only some feebly malignant epitheliomas of the skin. Gastrostomy seems to be the most favorable surgical procedure. The experiments with radium by Exner have not positively demonstrated any valuable results.

2. **Epilepsy.**—Wherry argues against the practice of considering the convulsion the chief and essential symptom in epilepsy, claiming that unconsciousness and its varying form of approach is of more significance. He thinks it is due to vasomotor spasm, which is itself probably a portion of the general tonic convulsion, and the theory of asphyxia is fortified in his opinion. Locking up the oxygen in the form of methemoglobin being the primary trouble and the cause of both the convulsions and unconsciousness, he thinks that back of the epileptic attack is a toxic condition and that investigation should not be devoted so exclusively to convulsions in the future as in the past.

3. **The Normoblasts.**—Arteaga holds that nucleated red blood corpuscles are the ancestors of the non-nucleated red blood cells and occur in larger quantities in embryonic life and that the spleen and bone marrow are constantly producing normoblasts, but this is only made evident to the eye when there is considerable loss of red cells, as in anemic conditions. The nucleus during extra-uterine life is less resistant and more short lived than during embryonic life, and that when the red blood cell leaves the marrow or spleen it loses the nucleus as a rule. He tabulates the results of his studies on dogs, cats and human beings, indicating the age, the time between autopsy and fixation, formula used and the results.

4. **The Puerperium.**—Gallant thinks many of the evils from which women suffer are due to uterine displacements from faulty posture after labor. They should not be allowed to lie on the back, but on the abdomen or side. It has been his custom to elevate the cervix by tamponing the vagina with sterile gauze tampons, changed every twenty-four or forty-eight hours, until the uterus has returned to its normal size and maintains its normal position. If it is abnormal before pregnancy this is the method to bring about normal conditions, but it would be advisable after using the tampon for a few weeks to insert a well-fitting pessary. He would not keep the patient in bed too long, as it encourages muscle weakness. The earlier out of bed the less weakness and the sooner the regaining of her former strength. Over-distension of the abdomen he meets by means of a properly applied binder and a specially fitted corset put on in the horizontal position and worn continuously when not lying down.

5. **Intratracheal Medication.**—Donnellan describes the syringe and canula which he used in intratracheal medication. The syringe is glass with an asbestos plunger; there is attached by a screw thread a nickel-plated canula bent at a right angle, with an olive-pointed closed tip, with four fine lateral openings near the end. The whole instrument can be readily sterilized by boiling. He first anesthetizes the larynx with a 4 per cent. cocain solution and then charges the syringe with a solution previously heated at about 102 F., two drams being the amount employed. The patient is instructed to protrude the tongue and hold the tip in a napkin, while the operator, guided by the laryngeal mirror, inserts the tip of the canula between the cords and while the patient takes a deep inspiration, slowly discharges the injection into the trachea. Care should be taken that it is given only during inspiration and that the tip of the canula is not allowed to touch the fauces, the base of the tongue or the epiglottis. If these details are faithfully carried out there are no unpleasant after-effects. The vehicles he has found most satisfactory for the injections are any of the fluid petroleum oils, olive oil and distilled glycerin. The medicaments found to be most serviceable are creosote, menthol, guaiacol, camphor or chloretone in 1 to 4 per cent. solution either singly or in combination, and other drugs added according to indications. Six cases are reported.

7 *Some Characteristics of Stegomyia Fasciata Which Affect Its Conveyance of Yellow Fever. H. R. Carter.
8 *The Unclassified Troubles of Women. Eugene Coleman Savidge.
9 *A Diagnostic Syndrome for Intracranial Syphilis. With Remarks on Prognosis and Treatment. Wm. Broaddus Pritchard.
10 *Claudius' Catgut. A New and Effective Method for Its Sterilization. Alexis V. Moschcovitz.
11 Case of Hodgkin's Disease Treated by X-rays. Edward B. Finch.
12 *Local Applications in Pneumonia. W. F. Church.

7. **Stegomyia Fasciata.**—Among the special characteristics of the stegomyia which affect its rôle as a carrier of yellow fever are, according to Carter:

1. *Its Distribution.*—This is generally between Lats. 43 N. and 43 S. on the coasts and low plains of Africa, Asia, and the adjacent islands; Australia and the Mediterranean basin of Europe. It is also general on the eastern coast of America from 38 N. to 35 S. Lat. On the west coast it is found at Panama and Guayaquil, and its existence is implied from Guayaquil to Acapulco. In the United States it is general on the coast and low plains of the Southern States, except Maryland.

2. It is conveyed by vessels indefinite distances (from Cape Town to Savannah Quarantine); in much greater numbers and more often by sail than by steam vessels.

3. It lives a long time—154 days being recorded of an infected insect. Once having acquired the power of transmitting yellow fever, it retains it apparently as long as it lives—59 days being recorded. A consideration of the three postulates above will render it advisable to safeguard the tropical countries of the East when communication is opened up between them and American ports infected with yellow fever, preferably by freeing the American ports of yellow fever.

4. It propagates preferably in artificial containers, but will propagate in pools where such containers are not available.

5. In America it has been reported only in the vicinity of human dwellings, and seems here not to be a sylvan, paludal or campestral mosquito. From 4 and 5 the war against this insect in America should be waged about the houses of men, and especially against water in artificial containers. The introduction of a water supply, piped to every house so as to do away with cisterns and water-jars, is the most important measure of sanitary engineering to free a town of this mosquito. Next to this is a system of drainage by covered drains to carry off the rain water and prevent pools. Cesspools are not objectionable on this score.

6. It unquestionably hibernates in the United States, but if the infected adult hibernates, either a very large proportion of them die, or else the infecting parasite must generally die in the hibernating mosquito. The first seems more probable.

7. It is essentially a house mosquito, and is inclined to stay about the premises where it has fed. Hence, the greater safety of the whole district of an infected city as compared with the residence portion.

8. It does not feed in the dark or in bright sunlight. Therefore, in bright daylight or at night without artificial light are the safest times to be in an infected place.

9. The cycle of the yellow fever parasite in the mosquito before it can be conveyed to man is generally in hot weather, about fourteen days or over. Prior to the accomplishment of this cycle (once called the "extrinsic incubation of yellow fever") the mosquito can not convey this disease.

10. It is probably usually conveyed aërially less than 100 yards. In Havana the infected insect is believed to be never aërially conveyed 200 fathoms—1,200 feet—from Havana shore. The direction of the prevailing wind during the day influences its aërial conveyance.

8. **The Unclassified Troubles of Women.**—These are, according to Savidge, largely those relating to what he calls the self-obliterated feminine element, the decline of the reproductive period and the maladjusted sexual relations, the psychology of the menopause and the danger at that period of women becoming uric acid machines and subjects of arteriosclerosis which tends to early aging and physical degeneration.

9. **Intracranial Syphilis.**—Pritchard lays down the following principles which he has learned to rely on during the past fifteen years. He says:

> Given a patient between the ages of 25 and 45, affected with any form of intracranial paralysis, which was preceded by headaches, of nocturnal onset or exacerbation, associated with vertigo and with insomnia, the insomnia occurring during the first half of the night, the paralysis developing during sleep, both headache and insomnia disappearing on the onset of the paralysis; the cause is syphilis.

We should not adhere to these limits too literally. A reasonable range of variation should be allowed, but in the main he claims that this is the very index of syphilitic involvement of the nerve centers. Other presumably familiar signs are mentioned, such as erratic distribution of the paralysis, tem porary palsies and paresthesias, and the preference of syphilis for certain regions and tissues, etc., is noted. The prognosis he considers in the majority of cases somewhat uncertain; that is to say, the prognosis can not be predicted with any certainty in advance of at least some initial response, or lack of it, to specific treatment. He believes in the iodids in the majority of cases. The nearer the primary condition the more useful mercury will be. There is no such thing as a fixed dosage of the iodids. When indicated he would give them not with iodism as a guide, but until the disease yields or the use of very large doses satisfies him that medication is useless. He has seen iodism from continuous 20-grain doses disappear at 40 or 50 grains and has repeatedly given 600 grains or more daily without special inconvenience.

10. **Claudius' Catgut.**—Moschcowitz advocates the use of Claudius' method of preparing catgut by immersing it in a solution of iodin 1 part, iodid of potassium 1 part, distilled water 100 parts, for eight days. The solution should be a very dark brown color or almost black and the catgut take the same color. He finds that it is flexible, knots well and that there is no danger of producing iodism or irritating action from it. The only valid objection that he finds is the action of the iodin on metallic instruments if it is kept in an instrument cabinet, but this objection is readily obviated.

12. **Local Applications in Pneumonia.**—Church finds local applications in pneumonia chiefly valuable for the relief of pleuritic pain and they should be selected, therefore, according to the relief afforded to the patient. When the pain is relieved the use of the application is ended and it should be discontinued. Cold compresses may possibly be of some value in selected cases.

13 *Vasomotor Center in Inhibition of the Heart. (To be concluded.) Charles E. D. Sajous.
14 Intussusception. John F. Erdmann.
15 *Prostatic Crisis. Samuel H. Friend.
16 Mucous Colitis, with Special Reference to Treatment. F. J. Runyon.
17 *Experimental Researches on Resuscitation After Death from Chloroform. (Concluded.) Robert Coleman Kemp and A. W. Gardner.
18 Diagnosis of Smallpox in the Papular Stage. (Concluded.) William Flegenheimer. R. Byington, J. M. Mason and George E. Hoffman.

13. **Inhibition of the Heart.**—Sajous' study of the subject warrants him, he thinks, to offer the following conclusions:

1. Inhibition of the heart is not caused by impulses transmitted to this organ by the vagus or spinal accessory nerves *per se*.
2. Inhibition is due to deficiency of blood in the walls of the heart, due in turn to narrowing of the coronary arteries.
3. The vagus contains vasoconstrictor fibers which terminate on, and cause narrowing of, the coronary arteries.
4. The bulbar vasomotor center is the source of the cardioinhibitory impulses transmitted to the heart by the vasoconstrictor fibers in the vagal trunk.
5. The cardioinhibitory impulses of the vasomotor center leave the bulb by vasoconstrictor fibers in the uppermost root of the spinal accessory, enter the ganglion of the root of the vagus and pass down the vagal trunk to the coronaries.
6. Reflex inhibition of the heart can be caused by vagal stimulation of the vasomotor center.
7. In reflex inhibition the afferent (sensory) impulses enter the bulb by the roots of the vagus and reach its nuclei; these in turn excite the adjoining vasomotor center; the inhibitory impulses of this center then pass to the heart by the efferent path described in the fifth deduction.

15. **Prostatic Crisis.**—The object of Friend's paper, as stated, is to show that one of the early symptoms of tabes, the perineal pain, is located in the prostate gland. In order to find out the seat of the pain he instructed his patients to: 1. Make pressure from over the perineum to ascertain whether the perineum was soft and whether they could determine any tenderness. 2. To palpate the rectum and feel whether there was a tenseness of the rectal sphincter. 3. To palpate with the finger up the rectum, to find the point of greatest tenderness. After each crisis the patients reported that the tissues of the perineum were yielding and not tender, that the rectum was soft and that they had no pain on inserting the finger up the rectum and that the point of tenderness was situated up the rectum in the anterior wall at a point corresponding to the prostate gland. They had no spasm of the muscles, as one of his patients could empty the bladder at the beginning of a mild crisis without trouble.

17. **Heart Massage.**—Kemp and Gardner's article is concluded in this issue and they give as their general conclusions that massage of the heart is both sound therapeutics and perfectly justifiable in all cases of death from chloroform or any anesthetic, or from drowning and allied conditions, when other means of respiration have failed. They insist on the importance of inversion of the patient and artificial respiration. Massage as described by them is method 3 (see the last issue, p. 1383), and is, in their opinion, no more radical an operation than the ordinary procedure when opening the pericardium or suturing an incised wound of the heart. Under the conditions noted they hold it to be perfectly justifiable.

27 *Ammonium Sulphate Method of Sterilizing Catgut. Weller Van Hook.
28 Severe Case of Major Hysteria (Traumatic Neurosis) Following an Accident; Recurrence of Symptoms After a Second Accident; Absence of Damage Claims in Both Instances. Theodore Diller.

20. **Lysol Solution in Cerebrospinal Meningitis.**—Seager's method of treating meningitis by the intraspinal injection of lysol solution has been tried by Manges in three cases. The first was apparently a meningococcus infection, the second virulent streptococcus. At the present writing all the patients are perfectly well. The details are given. He presents the results of these three cases with some reserve, as he thinks a more extended trial is necessary, but so far as they go they are better than the results that have followed the varied plans of treatment in the severer cases at the Mt. Sinai Hospital. The treatment, moreover, is harmless. The quantity of 1 per cent. lysol solution injected is 3 to 9 c.c. for children and 12 to 15 in adults. The injections are made daily until the fluid is clear. If there is much hyperesthesia or the patient is very rigid, a short chloroform narcosis is advisable. He promises to report later experiences.

22. **Mattoli's Method for Gastroenterostomy.**—Savini describes the various methods and the Mattoli modification of the von Hacker by first anastomosing the jejunum to the posterior wall of the stomach as in the von Hacker, uniting and anastomosing the two branches of the jejunum together about three inches from the gastroenterostomy as in the Braun-Jaboulay. The afferent branch of the jejunum between the two anastomoses is held between the thumb and the middle finger of the left hand, placing the fingers longitudinally. The pressure of the index finger forms a groove in the intestine and the two uniting ridges are sewn together with a number of stitches of an interrupted or continuous suture, changing this section of the intestinal tube into a solid cord. This, he says, prevents circulus vitiosus, the bile and pancreatic juice can not flow into the stomach, but are entirely drained into the jejunum. The operation is more safely and quickly performed than the operation of Roux. Moreover, the surgeon is not compelled to carry out the operation completely. He can stop at any step in either of the three stages.

24. **Tuberculosis of the Testicle.**—Blake would castrate in case the testicle or epididymis are involved. He does not favor epididymectomy if the epididymis seems to be alone involved, since he can not be sure of this. The gland is useless when the epididymis is removed unless for internal secretion, and one testicle suffices for that function. In case both testicles are involved he would leave one testicle, if possible. In all his operations he has removed the vas deferens with usually a portion of its ampulla. He believes that the infected seminal vesicles should be excised in every case in which the disease is limited to the genito-urinary tract: 1. To remove tubercle foci in general. 2. To prevent implication of the remaining testi-

cle and the urinary tract. It is a difficult operation, but unless there are other contraindications its dangers are less than of allowing the tubercle foci to remain. In regard to the technic in operations on the vas deferens and seminal vesicles he has found the following method satisfactory:

> In removing the vas with the testicle, the testicle is first excised with any skin that may be invaded, the incision is then carried up to a point *opposite* the internal ring and through the aponeurosis of the external oblique. The vas deferens having been separated the remainder of the cord is divided, and the vas being drawn on the peritoneum is pushed away from it with the finger until it is freed down to the ampulla. A ligature is then tied about it as low down as possible, or it is evulsed, the finger of the other hand separating it at the ampulla. The wound is then closed, as in the repair of hernia. By this method a portion of the ampulla is generally removed with the vas. This method is usually preferred to that of Büngner, in which the vas is evulsed from the external ring. When I have removed the seminal vesicle, I have first excised the testicle and vas deferens in the manner describd and have then attacked the vesicle through the curved perineal incision known as Zuckerkandl's. After freeing the dorsal surface of the prostate, the seminal vesicle is exposed by incising the layer of the rectovesical fascia binding it to the bladder. It can then be shelled out without much difficulty. At the same time any lesion in the prostate can be attacked and handled as its extent of importance may require.

25. **Tuberculosis of the Urinary Bladder.**—Johnson announces his conclusions as regards the treatment of tuberculous cystitis as follows:

> (1) If other tuberculous lesions of the genito-urinary tract exist their operative removal is sometimes followed by improvement and even cure of the process in the bladder, provided the patients are placed under the most favorable hygienic surroundings. (2) Operative treatment of the bladder alone in the presence of tuberculous lesions of other portions of the urinary tract is usually harmful rather than beneficial. (3) The local treatment of the tuberculous bladder by means of injections or applications through the urethra is generally useless and often very deleterious. (4) The internal administration of the drugs known as urinary antiseptics is generally useless. (5) Palliative operations, such as suprapubic drainage, may be useful in advanced cases. (6) The general or hygienic treatment, suitable climate, out-of-door life, etc., offers these patients the best hope of recovery. (7) Such hygienic measures should be preceded by the operative removal of tuberculous foci in the kidney, the epididymis, the prostate and the seminal vesicles if such exist and the patient is still in sufficiently good condition to bear operative procedure. (8) In these rare cases where the bladder alone is affected over a moderate area only, the operative removal or destruction of the diseased tissue may be followed by improvement and even cure.

27. **Catgut Sterilization.**—Claudius' method is condemned by Van Hook, who finds that catgut has not an agreeable handling quality and becomes fragile after prolonged storage. While we must accept the claim that iodized catgut is sterile, we have a comforting sense of perfect security in using suture material that has been subjected to the action of boiling water. For these reasons he has returned to the ammonium sulphate process of Elsberg with such satisfaction that he feels it his duty to commend it. As the result of experience in more than two hundred operations in the Wesley Hospital he recommends the following method of selection and preparation:

> At the outset a catgut of unimpeachable quality must be chosen and the surgeon will do well to arrange for a continuous supply of uniformly reliable material. It should not have been weakened by bleaching or polishing. Select raw, rough, unbleached material. Soak for a week in pure ether or a mixture of chloroform one part and ether two parts. Wind on glass spools in single layers. Soak for three days in aqueous solution of chromic acid, 1 to 1.000. Boil for twenty minutes in water to which, while boiling, chemically pure ammonium sulphate has been added until the crystals cease to dissolve. Wash the catgut for half an hour in cold sterile water. Store as desired. I place the spools in a solution of corrosive sublimate, one part in 95 per cent. alcohol, one thousand parts. Should the material become infected, it may be reboiled.

Boston Medical and Surgical Journal.

May 12.

29 *The Hystero-neuroses and Their Relation to the Physical Examination of All Women Patients. Daniel H. Craig.
30 *Tubercular Meningitis in Adults. Henry Jackson.
31 *Claudius' Iodized Catgut. Horace Binney.
32 *Concerning the Danger of Infection to the Attendants of Tubercular Patients. Louis F. Bishop.

29. **Hystero-Neuroses.**—The importance of a complete physical examination of all women patients with special reference to the symptoms commonly diagnosed as hysteria is insisted on by Craig. He believes that the gynecologic specialist is as likely to overestimate a hystero-neurosis as the general practitioner is to overlook it. He lays down as a rule for his students never to accept any symptom as an hystero-neurosis until every other possible cause has been rationally excluded. He does not think that a pelvic examination of every woman is necessary, and outlines his method as follows: 1. A routine history taking. By this he does not mean filling up the spaces of a printed blank, but a thorough recording of the history, beginning by inquiring in the most ordinary way to get a full menstrual and pelvic history without in the least offending the delicacy of the most scrupulous. The history completed, the patient's heart and lungs are examined by auscultation and percussion. On account of the intimate relation between the respiratory and pelvic organs, catarrhal conditions of the upper air tract are to be looked for. The abdomen next receives attention, the liver and spleen being percussed and attention given to Robson and Boas' points for evidences of gallstones. The kidneys are next investigated for palpability, mobility or enlargement and the course of the ureter followed down to the pelvic brim. The position and size of the stomach, colon and small intestines are next examined by auscultatory percussion and the colon and iliac region palpated for evidence of appendicitis, ovarian tenderness or colonic impaction. The hypogastrium is palpated for evidence of bladder enlargement or tenderness. The history will indicate which parts require the most thorough examination. With a supersensitive patient he believes in using nitrous oxid in case of pelvic exploration. The thighs and legs are examined only when the seat of special symptoms. This examination, he claims, does not consume too much time, and is of advantage not only to the physician, but to the patient. Several cases are reported illustrating the local causation of symptoms that had been attributed to hystero-neuroses.

30. **Tubercular Meningitis in Adults.**—Jackson points out the important symptoms of tubercular meningitis such as fever, headache, general malaise and often leucocytosis. The latter is really important only as a means of eliminating typhoid, but there are two classes of symptoms directly dependent on organic changes in the brain and meninges on which to base a diagnosis, disturbances of the pulse rate and paralyses of various muscles, especially of the eye and face. In the early stages of meningitis or in cases of moderate effusion we find a slow pulse as the result of irritation of the vagus while in the later stages we have an exceedingly rapid one from paralysis of the same nerve. A slow pulse or a relatively slow one in a very sick person should always raise the suspicion that there is some factor causing the lowering. The pulse of typhoid fever is slow as compared with other diseases with equal fever, but this does not apply where individuals are so sick as to suggest the probability, or even the possibility, of meningitis. He has seen cases where the slow pulse was a source of relief to the attending physician but a very prompt cause of apprehension to himself. A pulse of normal rate or one with a rapidity such as might be expected from the general conditions of the patient, is a strong presumptive proof that the case is not cerebral in origin. Paralysis of the eye muscles, or one or more muscles of the face, may be of the greatest value, only they may be so slight that doubt whether the deviation might not be natural to the individual may arise. Special attention should be paid to the existence of paralysis as it is easily overlooked when the patient is very sick. It is not rare in hospital practice to meet with cases of tubercular meningitis in adults. As they are quite different, in his experience, from those observed in practice, Jackson reviews those observed in the Boston City Hospital, with the addition of one seen in private consultation. He has notes of 18 cases, 7 between the ages of 18 and 25, 8 betwen 25 and 30, and 3 between 40 and 50 years. The previous history varies and 14 gave no history of preceding disease. In one case no history at all was obtainable. In 3 there was a history of subacute disease two years prior to hospital entry, suggesting subacute tubercular processes. In making a diagnosis of tubercular meningitis the lack of evidence of pre-existing tubercular trouble is no strong evidence against the diagnosis. In only 2 of the cases had the pathologist failed to find evidence of old tubercular processes, but none showed extensive tubercular disease susceptible of diagnosis by recognized clinical methods. The period of sickness varied, but was generally shorter than the incubation period seen in children. The prodromal symptoms in all were indefinite, suggestive of many acute febrile diseases rather than pointing towards a definite cerebral trouble. A good idea of the general impression made by them before examining is shown by the fact that in most cases the Widal

examination had been made. In all the cases but one the pulse was slow in the first part of the acute stage. In the last two or three days of life it was high. Comparing the slow pulse rate with the stupor, delirium or noisy maniacal conditions and the marked discrepancy between the pulse and the general condition, show its dependence on the cerebral trouble. The temperature is important, rarely over 102.5, usually from 100 to 101. The white count in 9 cases showed a smaller number than in acute cerebrospinal meningitis. The small leucocytosis favors the diagnosis of tubercular meningitis as against acute cerebrospinal meningitis. Lumbar puncture was done in 8 cases, in all showing high pressure of cerebrospinal fluid, but in only 1 case was the tubercle bacillus found on microscopic examination. In these respects it was very different from that of cerebrospinal meningitis, where the fluid is purulent or semipurulent and the organisms are easily obtained by culture. Examination of the fundus oculi gave little information. Retinal tubercles are certainly rarely found. Other symptoms such as local paralyses, retraction of the head, etc., were observed in the author's cases. Three of the patients died in less than two weeks of the onset of the acute symptoms, several died in less than one week and two cases lived for three weeks. Small areas of chronic tuberculosis were found in 16 of the 18 cases and other tubercular conditions, such as areas in the lungs, caseous bronchial lymph glands and tuberculous hip. Acute miliary tuberculosis was found in 7 cases and general acute miliary tuberculosis in 5. The cord was involved in a large number of cases as well as the meninges of the brain, namely, in 8 cases. He thinks this is not usually considered to be so common. A history of two cases is given.

31. **Claudius' Iodized Catgut.**—The advantages of Claudius' catgut are detailed by Binney, who considers it superior to other catgut in that it is invariably sterile, is readily absorbed, is easily and simply prepared with little trouble and is comparatively cheap.

32. **Tubercular Infection.**—Bishop points out that tuberculosis is not infectious or contagious in the sense that scarlet fever and measles are. The average individual enjoys immunity against tubercular infection to a certain extent. We are all exposed to the germs, but we do not all get tuberculosis. The tubercle bacilli can be introduced into the body with ordinarily no ill effect excepting in cases of very severe infection unless the person is repeatedly inoculated and the natural immunity temporarily broken down. Even then, if the individual is not susceptible, he will throw it off. The germs, however, are so widely distributed once in a while that a large number of persons are infected and the disease gets a start. They are sick for a little while, but do not recognize the condition and get well. The only way it is found out is in examining the lungs of those dying of other diseases, when we find that a large number have had a slight degree of tuberculosis. Tuberculosis is only contagious to those who are susceptible to it. This is an important point, because in it lies the principle of the only treatment known for tuberculosis; that is, to restore to the individual the natural immunity which he enjoyed before becoming infected, and this is accomplished by measures directed to the system in general. So far as the danger of taking care of tuberculous patients is concerned it is practically nil.

36.—Ibid., p. 1225.

37. **The Colon Bacillus Infection of the Female Genito-Urinary Tract.**—Ely reports cases and remarks that he has presented the paper because he believes many cases of colon infection pass unrecognized. He also thinks that cases of apparently simple vaginitis and cystitis are often followed by severe toxemia and septicemia, even in young children and adults past the age when infections are likely to occur. It could be diagnosed and more promptly treated if a competent bacteriologist were employed to confirm the clinical diagnosis. He protests against the unguarded use of so-called urinary antiseptics. Toxic symptoms, in his experience, occur from these. Topical applications by means of the cystoscope with apparently little practice can be made with the modern instruments by the general practitioner and greatly relieve the distressing symptoms of diseased bladder.

38.—See abstract in THE JOURNAL, xli, p. 1224.

40. **Hemorrhoids.**—Mayne prefers the carbolic-acid injection treatment, and thinks that harm has been done by Andrews, who first discovered and published the method in so decidedly condemning it. Mayne holds that its success is fully equal to that of other methods, and it has a number of advantages. 1. The ease with which patients will submit to the treatment. 2. No pain. 3. No detention from business or other duties is necessary, except in cases of imprudence. 4. No general anesthetic is required, except in complicated cases. 5. There is not the retention of urine which usually follows the clamp, cautery and ligature operations. Granting there may be occasional recurrences, the chance of undergoing a second operation is preferable to the more radical ones.

51 Nephrolithiasis. C. H. Churchill.
52 The Surgical Assistant. (Rectal Operations.) Walter M. Brickner.

48. **Conservatism in Gynecologic Surgery.**—This is considered under four heads by Wakefield: 1. Vaginal drainage for pelvic abscess, septic edema and hematocele. The place of this procedure is established at the present time. It may simply be palliative or produce a permanent symptomatic cure. 2. Conservative operations on the uterus. Myomectomy is now generally advocated, but contraindications are given such as conglomerate growths whose relation with the uterus can not be defined; pelvic inflammatory disease, grave anemia, grave organic disease of the vital viscera, when the tumor is so large as to make the resulting wound difficult of closure and the involution of the thinned uterine walls dubious, that is, tumors

extending above the umbilicus, and lastly, an approaching menopause. Cullen advises against attempting a myomectomy in the presence of inflammatory disease of the adnexa, but Wakefield thinks that by paying attention to the above noted exceptions, myomectomy has been well established as the only treatment for uterine myomata. 3. Conservative operations on the ovaries. The general consensus of opinion is in its favor under almost all conditions. The only conditions that justify a sacrifice of the ovaries are large cysts, abscesses, hematoma or fibroids which have entirely destroyed all the healthy ovarian tissue; second, the presence of malignant disease, and third, the presence of tuberculosis. 4. Conservative operations on the tubes. Several cases are here reported. The opinions of surgeons differ. The author's conclusions are summarized as follows:

> 1. We should be very cautious about applying conservatism to cases known to have been recently infected. 2. The advent of an acute attack of localized peritonitis in a patient suffering from chronic infection, in other words, an acute "lighting up" of an old infection, does not contraindicate conservatism. 3. The presence of acute infection in one tube, which it is deemed advisable to remove, does not call for removal of the other tube also, unless it is similarly diseased. 4. The longer the patient has been infected the more likelihood there is for the pus or inflammatory products in the tube to be sterile, and the more safely may we consider conservatism. 5. Of the two procedures, resection of the tube and amputation of the tube, the latter is the safer procedure, as we do not then leave behind a lot of thickened, inflamed and more or less infected tissue to menace our results, and that a stump of a tube is capable of carrying an ovum to the uterus has been demonstrated.

53 *Constitution and Biology of Brewers' Yeast. Heinrich Stern.
54 *The Treatment of Cancer by Its Own Toxins. P. J. McCourt.

53. **Yeast.**—Stern's article is an instructive account of yeast and its growth, pointing out the advantages of the pure culture used in many cases, and a study of the different kinds of yeast on economic principles.

54. **Cancer.**—McCourt calls attention to a former paper in which he described his method of preparing the cancer toxin. The cancer-tissue is pressed and triturated in purest vegetable glycerin, and the juices thus obtained are separated until micro-organisms are no longer found. The resultant fluid contains all the ptomaines or alkaloids of the cancer virus as well as those of other diseases associated with them in the subject from whom the virus was collected. They are highly toxic, but when reduced to medicinal strength and exhibited to a cancer patient having history and complications nearly identical with those of the person who furnished the toxin the latter will act as an antidote to the poison generated by the cancer cell. He reviews some of his former publication and gives some experience with these toxins.

55 *The Increasing Mortality from Pneumonia in Baltimore and Its Causes. J. Hall Pleasants.
56 Massage in Modern Therapy. Reni Tauer.

55. **Pneumonia.**—Incited by recent publications as regards the increasing virulence of pneumonia Pleasants has studied the statistics of Baltimore for the past fifty years and finds that there has been a gradually rising curve for at least half a century with a steady and gradual increase up to 1890. He emphasizes this fact because whatever influence influenza may have had it must have been subsequent to that year. He considers successively several factors which may co-operate in producing this increasing mortality: 1. Increased density of the population; the greater prevalence of pneumonia in densely populated countries has long been noted. 2. General prolongation of life by several years and reduction in the mortality from intestinal diseases in young infants increases the number of individuals in the extremes of life who are particularly susceptible to pneumonia. 3. Climatic changes. This is an uncertain factor. He thinks there may be something in the overheating of dwellings as lowering resistance. 4. The census returns show a greater susceptibility of foreigners to pneumonia and a higher death rate among them. 5. The negro element in the population. In Baltimore this is an important factor. The high death rate among the negroes is just about balanced by the very high birth rate. 6. More accurate diagnosis and exact terminology in the vital statistics. Formerly a large number of cases of obscure and senile pneumonias escaped diagnosis, and with the increased use of the stethoscope they are now less frequently overlooked. 7. The decreased death rate from consumption as a causal relation to the increased pneumonia mortality has been suggested. He hesitates to express an opinion on this point. 8. The increased virulence of the pneumococcus. This is only conjecture not yet supported by evidence. A certain number of cases of pneumonia are not even due to this organism. 9. Influenza, which has come into play since 1890. We are forced to the conclusion that what we call the grippe has a close and intimate relation to many cases of pneumonia, and if not a cause, is certainly a predisposing factor. 10. Some unknown factor on which we need not speculate. We must confess our ignorance and attribute part of the spread of the disease to a factor as yet unknown. He says there is nothing peculiar about the pneumonia situation in Baltimore at the present time. The same state of affairs exists elsewhere. The problem is one of national importance. We can not say that the situation looks hopeful from the standpoint of general prophylaxis.

61 Puerperal Septicemia. J. A. Regner.
62 Neurasthenia—Alcoholism—Insanity. William Lee Howard.
63 Iodized Catgut. A. W. Abbott.

57. **Acute Diseases of the Abdomen.**—Holman reports several cases of peritonitis occurring from perforation, appendicitis, etc., and he favors for the treatment of these cases rest in bed and abstinence from food or cathartics by the mouth, salines should not be used, for mild cases may become severe; but an enema may be employed if the constipation exists. The laity should be instructed as to the value of early operation. If pus is present the Fowler position is of value, but if postoperative infection occurs, Clark's position should be maintained. In severe intra-abdominal conditions it is well to have as a consultant one who is accustomed to intra-abdominal pathology from practical observation.

58. **Diphtheria.**—Ramsey points out the value of antitoxin in diphtheria, holding that if given early enough it is a specific in at least 95 per cent. and greatly reduces the mortality, even in the later cases. Sufficient quantities should be given. Death when it occurs results in many cases from the damage done the heart and nervous system before antitoxin is given. There is a small percentage of cases in which antitoxin seems to be ineffective. Post-diphtheritic paralysis is apparently no less frequent than before antitoxin. Intubation and tracheotomy should be required if the heart shows evidence of weakness, and should be done with the patient in the horizontal position. We should remember that heart symptoms sometimes occur as late as several weeks after apparent convalescence. A careful examination of the heart is required daily. Alarming symptoms are sometimes produced by antitoxin, and we should employ it with some reserve, using all the means in our power to make a proper diagnosis, but always in doubtful cases, giving antitoxin the benefit of the doubt.

59. **Pneumonia.**—Johnson's view is a little different from the ordinary. He holds that pneumonia is not an infection, arguing from the fact that there is practically no incubation period in some cases, and that auto-intoxication is the more probable cause. The urotoxicity is gradually diminished during the course of pneumonia as proven by experiments. This he thinks is a point in favor of his theory. He protests against the idea that we can do nothing in pneumonia. No two cases are alike. The patient, not the disease, must be treated. We must open the emunctories of the body but not debilitate the system. In private practice he advises gentle regulation of the bowels, mild diuresis and diaphoresis, alleviation of pain by heat and morphia hypodermically if necessary. If symptoms of debility manifest themselves stimulation by strychnia, digitalis and alcohol according to the symptoms are indicated.

64 *Mouth Parts and Salivary Glands, Normal and Otherwise, of the Yellow Fever Mosquito. George E. Beyer.
65 The Advantages of Medical Organization. J. F. Bouquoi.

64. **Yellow Fever Mosquito.**—In this elaborate article, which is quite fully illustrated, Beyer describes and discusses the possibility of the parasitic nature of the germ of yellow fever and offers the following conclusions:

1. That the glands of contaminated mosquitoes of the age of twelve days or more contain phases of development of an animal organism, the last one of which consists in an exceedingly small ovoid hyaline body of about one micron in length. 2. That this organism or any of the described phases have thus far not been observed in non-contaminated mosquitoes. 3. That the last phase, the so-called "Sporozoites," being found in the lumen of the gland of an insect which had produced a typical infection, must be regarded with suspicion of being the causative agent of the disease. 4. That proof of this effect can only be arrived at by experiments indicated in the body of this paper.

69 *Necessity for the Annual Systematic Examination of School Children's Eyes, Ears, Noses and Throats, by School Teachers. Frank Allport.
70 Cataract—a Historical Review of Its Surgical Treatment. Samuel H. Brown.

67. **Distant Color Signals.**—Oliver here describes what Wilson has aptly called short-sightedness to color, and reports a case in which a man who passed the ordinary tests discovered his own deficiencies and stood an examination. He thinks the methods for color testing at the present are inefficient for the detection of many low degrees of subnormal color perception, the most dangerous and least suspected class. Every candidate for color testing should be medically proved to be free from bad habits, systemic disturbance and ocular disease, and accurate notes of the character and degree of the color sense should be kept and added to at regular intervals. All testing for color among the Army, Navy, marine and railway employes should be conducted in the situations which are occupied by the subjects during work, and at distances which are employed during signaling, also during various stresses of the weather to which the candidates are subject. They should be done during the time of the day and with the illuminating exposures that are used during their daily employment, and with adaptation of materials that are to be gazed at at their regular work. All the test colors must be kept at uniform standards of relative distinctness, saturation and brightness ordinarily used.

68. **Keratoconus.**—The various methods of treating this condition are described by Lewis, who thinks that the most generally adopted one of late years and the least painful is the cauterization of the apex with the actual or galvanocautery. He describes the method. The majority of operators first cauterize the apex with an oval electrode, and then pierce the eschar with a fine-pointed electrode. They dilate the pupil, and cocain is used, as no speculum is employed. The oval electrode is placed cold over the apex and withdrawn as soon as it has been brought to a red heat. Then with a needle electrode, the size of which depends on the amount of contraction required, the center of the apex is pierced and the needle quickly withdrawn so as not to heat the aqueous too much and produce traumatic cataract, for the same reason the electrode is kept down from white heat. This procedure is easily performed, does not result in anterior synechia, allows rest and contraction of the cornea by the slow and continuous drainage of the anterior chamber and leaves a small scar. A moderately tight bandage is kept on most of the time following the operation, and increased tension may be combated with eserin. A few bad cases have been reported from this method, but he has had more good results with fewer bad results than with any other. It is now considered a classic treatment.

71 *The Pathology of Diabetes. Richard M. Pearce.
72 *The Physiologic Chemistry of Diabetes. David L. Edsall.
73 *Medical Treatment of Diabetes. W. H. Thomson.
74 *The General Management of Diabetes. Frederick C. Shattuck.

71. **The Pathology of Diabetes.**—Pearce summarizes the relation of the pancreas and especially the islands of Langerhans to diabetes as sharply separating at least one form from all the others, and offering a distinct departure for the study of those forms of glycosuria, to which some knowledge of the complexity of carbohydrate metabolism may be assumed to be due to the destruction of other organs.

72. **Physiologic Chemistry of Diabetes.**—Edsall reviews the publications on this subject, and remarks that the important facts known are unfortunately few. When sifted down they are chiefly that the pancreas exercises a very great influence over carbohydrate metabolism, but it is not known how this is done. It probably does not do so merely by providing glycolytic ferment, but possibly by interfering with the glycolitic activities of other tissues. It is becoming evident that carbohydrate metabolism is intimately associated not only with the pancreas, but also with other tissues, and is of somewhat greater complexity than has heretofore been considered. At present one is justified in at least suspecting that carbohydrate metabolism is comparable in its complexity with that of proteid metabolism.

73. **The Medical Treatment of Diabetes.**—Thomson considers that glycosuria which has lasted more than one year is diabetes. Time is the principal element in its diagnosis. He would study the family hereditary proclivity. He finds that there is no race so subject to diabetes as the Jews. The question of age and state of nutrition of the patient are to be considered. He makes it a point to determine what is the daily output of urea as well as the sugar. If the percentage of urea is high, there is emaciation, even if the patient is adipose. The sugar may disappear, but the urea excretion remains one-half more or double what it ought to be. Obesity in a patient calls for special medication on account of the danger to the heart. If he has oxalates alternating with abundant uric-acid crystals in his urine, all the better. As to medicines, he rarely gives opium, codein or any of the opium derivatives. The nervines are only functional remedies, none of them can touch the diabetes itself, they are needed to relieve the symptoms or in emergencies. For a number of years he has advocated the use of cod-liver oil in diabetes, and reports cases of its beneficial action. Next to cod-liver oil, he would place iron, and the old-fashioned Hooper pill is very useful when there is a tendency to constipation. He thinks that the internal secretion of the pancreas in the islands of Langerhans is of the nature of an enzyme, which can propagate its action from very small beginnings. He suggests that in examining the urine we should not merely look out for abnormal ingredients, but also investigate whether the normal constituents are present in proper proportion, and if we do this, we would find more cases of defect than we do at present. The free administration of antiseptics, he thinks, is more promising in diabetes than any other means, cod-liver oil and iron excepted. He includes arsenic in this class of antiseptics. The alkalies in the form of mineral waters have held a deserved place, but their action is always to be borne in mind; that is, the free use of all saline waters tends to increased waste, and they should not be given to anyone really losing flesh. Diabetes is serious in that it virtually compels starvation of an essential element of food. The system must have sugar. If it does not get the sugar it can use, it will turn to its own proteid for it. Along with this perversion, poisons begin to be generated, of which oxybutyric acid and its derivatives are doubtless only a part. We can not neutralize them. In case of diabetic coma, he relies on one of the most trustworthy diuretics which we possess, namely, prolonged intestinal irrigation with normal saline solution. The best instrument is Kemp's rectal irrigator. Hypodermic injections of 7 to 14 grains of camphor in sterile almond or olive oil best sustain

the failing heart, while diluted milk holding all the sodium bicarbonate which the patient can take is the only recourse for food.

74. **The General Management of Diabetes.**—Under the head of diabetes, Shattuck includes all grades of failure to burn sugar in the organism. The principles which should guide us are: To first thoroughly test the amount of urine and sugar without change in the diet or mode of life, and except in cases where the condition is evidently either very mild or severe, he thinks it is best to enforce absolute or nearly absolute diet at once. If acetozone and diacetic acid are present, a radical and rapid change of diet is dangerous. The diet list should be adapted to each patient. He does not believe in the printed lists given out by manufacturers of food products. An approximate adjustment of the food to the requirements must be aimed at, and the body weight noted at stated intervals; more frequent at the beginning of treatment than later, perhaps. The weight with the general symptoms or their lack and the condition of the urine will generally prove safe guides as to the judiciousness of the diet. In favorable cases under a strict diet he expects to see the sugar disappear in two or three weeks, the weight increasing. How long it should be kept up depends on the type of the disease, which depends largely on the age and weight of the patient. In the milder cases he would keep the patient on a strict diet for one or two months, and then test the tolerance of the stomach for starches, by giving a little bread daily, increasing the amount as the tolerance warrants. In the more severe cases which are rendered sugar-free with difficulty, one must be more careful. He has discarded the use of diabetic breads, as he finds from his experience that few of them are reliable. He has never used the skimmed-milk cure, as recommended by Donkin. It does not seem to him rational, though he admits that it does not fail to work well in some cases. A day of starvation every two or three months is useful in some cases. The bowels should receive careful attention. Baths, etc., should be given, and the bodily temperature carefully regulated by the clothing, etc., avoidance of worry and anxiety insisted on. Muscular exercise, properly regulated, is of use. A change of climate may be advisable.

82 The Kahunas—Witch Doctors or Sorcerers—of the Hawaiian Islands. Blair D. Taylor.

78. **Gunshot Wounds.**—The experience of the Cuban surgeons in the insurrection prior to the American intervention, are described by Poey, who thinks that for military purposes the Mauser and Krag bullets are comparatively useless, as they can not stop the disposition to fight unless they hit a very important and vital part. The wounds are slight and heal quickly. The brass-coated bullet is worse and more destructive. The ordinary lead 43-caliber of the Remington rifle is also a dangerous and destructive missile. The less surgical interference in military practice the better. Common sense and antiseptic treatment will do more for the treatment of the Mauser and the like bullet wounds than all the surgical interference possible. With brass bullets, however, an exception is made, but then only in special cases. First-aid dressing will do better than all the surgical interference known.

87. **Chronic Dysentery.**—Barbat has treated cases of dysentery in returned soldiers from Manila by surgical methods, doing a colostomy and producing an artificial anus. His conclusions are that a number of patients with chronic dysentery do not recover under medicinal treatment. These are principally the amebic type, with prospects of exacerbations, abscesses of the liver, bowel contraction and marasmus. These complications may be obviated in many cases by a timely operation, which in itself is not particularly dangerous. The relief afforded is immediate, and will result in cure in many instances. In the cases reported, one patient after closure of the artificial anus became dissipated and developed a liver abscess, thus showing that we can not always be sure of having destroyed all the amebæ and the peristaltic action and absorbing capacity of the bowel will permit the amebæ which may be present to pass through into the circulation and cause abscess of the liver. In the second case the treatment was successful.

10 *Treatment of Acne, Furunculosis and Sycosis by Therapeutic Inoculations of Staphylococcus Vaccine. A. E. Wright.

1. **Hernia.**—The operation here described by Pringle is admittedly very similar to the later method of Halsted with the utilization of the cremaster. He, however, prefers to put the flap made of cremaster and other fascia in front of the internal oblique, which he explains is not Halsted's plan.

3. **Gastrojejunostomy in Non-Malignant Stomach Conditions.**—Barling favors gastrojejunostomy for pyloric stenosis to put the stomach at rest, to stop hemorrhage from ulcer, to relieve pain, and for atonic dilatation of the stomach with marked proptosis. In pyloric stenosis the results have been generally good. Hemorrhage and pain symptoms have been relieved, but relief may not be permanent, as in the two cases in his experience. The results have been discouraging in atonic dilatation of the stomach, etc. His experience on the whole is in favor of the suture, though he can not ignore the quickness and ease of the Murphy button, and in some cases it is indicated. He has performed gastrojejunostomy 18 times, with 2 deaths. Eight of these were by suture only, with no death; 2 were by suture and absorbable bobbin, with 1 death; 8 by the Murphy button, with 1 death. In the case with the absorbable bobbin, death was caused by unexplainable hemorrhage. With the Murphy button it was due to the late operation when the tissues were not sufficiently capable of repair and the button ulcerated through. The absolute necessity of saving every minute possible necessitated its use, and in the suture cases troublesome vomiting occurred in 4. In 2 cases treated by suture and bobbin, it did not occur, nor in cases where the Murphy button was used. He describes his technic as follows:

> To gain access to the stomach the abdomen is freely opened in the middle line, the transverse colon and great omentum are turned upward, the transverse mesocolon is divided, care being taken to avoid the arches of vessels supplying the colon, and the posterior surface of the stomach is seen. Lying close to it is the junction of the duodenum and the jejunum to the left of the vertebral column. A portion of the jejunum not less than 12 inches from this junction is selected for the anastomosis; it is emptied and lightly clamped with Doyen's forceps so as to control its canal and its circulation. A pouch of stomach, drawn through the opening in the mesocolon, is similarly treated, and the parts surrounded by sponges are, as far as possible, brought outside the peritoneal cavity. The junction is made by two rows of sutures; the outer, including the peritoneum and muscle, is interrupted once when it has completed a half circle, and is then laid aside. Stomach and jejunum having then been opened, and the larger vessels in the stomach incision ligatured, the second suture is applied, including all the coats, and it makes a complete circle without interruption. The parts have been held in apposition by an assistant who manipulates the clamp forceps, and at this point the forceps may be taken off before the outer row of suturing is resumed and completed. The parts are swabbed over with normal salt solution and returned into the belly.

Several illustrative cases are reported.

10. **Staphylococcus Vaccine.**—Wright reports cases of furuncle, acne and sycosis treated with staphylococcus vaccine of standardized strength. He thinks it advisable to use one made with the particular strain of micro-organism that has acclimatized itself in the patient's organism.

14 Mesenteric Cysts. E. P. Baumann.
15 Amaas, or Kaffir Milk-pox. W. E. De Korte.
16 A Case for Diagnosis. W. Johnson Smyth.

11. **Blood Disorders in Early Life.**—Hutchison describes the conditions of the blood in early life; the high percentage of red cells and the rapidly decreasing amount of hemoglobin produce a sort of semichlorotic condition in infants after the first half year. The area of red marrow blood-producing surface is much larger in proportion in infants. There is no reserve power of formation as there is in the adult, and the infant must live up to the limits of the blood-forming capacity. This may perhaps explain why children stand hemorrhages badly and why they become anemic on slight provocation. The leucocytes are discussed at length, and he follows Ehrlich's idea that the non-granular cells are largely produced in the adenoid tissue. The red marrow at this period of life is engaged almost to the limit of its functional capacity in the production of red cells individually less richly charged with hemoglobin than in the adult. The periods of the granular formation of white cells is similar to that in the adult though the non-granular cells are present in much larger absolute numbers, and the adenoid tissue producing them is abundant, active and widely diffused. While this specialization of the function of the marrow and adenoid tissue has taken place in the child as in the adult, the former standing nearer to the

period of fetal life may be expected to be able, under stress of disease, to revert more easily to fetal methods of blood formation and to show in pathologic conditions a less sharp degree of specialization on the part of the marrow and adenoid tissue, respectively. A combination of a high absolute number of non-granular cells with a relatively low percentage of hemoglobin constitutes the hall-mark of the infantile type of blood, and in all conditions of profound anemia in childhood these characteristics are markedly accentuated. Passing from this physiologic description, he describes the conditions of congenital abnormalities in infants, primary and secondary anemias, and remarks on the notable rarity of pernicious anemia in childhood, and on the condition of infantile scurvy. He does not fully accept Corlette's opinion as to the part played by the citrates in this condition. He has found that the artificial administration of calcium citrate, which so abounds in milk, is therapeutically less useful than the artificial salts of potash.

12. **The Tissue-Lymph Circulation.**—Oliver's second lecture reviews the effects of fatigue, exercise, rest and sleep, respiration of gases, internal secretion, temperature, gravitation, etc., and discusses the question whether tissue lymph is an exudation or secretion and whether there is an intermediary circulation. He concludes with some practical deductions as regards the dietary of gout and the use of organic products as remedies. His conclusions are briefly summarized as follows:

> 1. Tissue lymph is intermittently effused, for example, after the ingestion of food, during exercise, rest after exercise, and during sleep. 2. The rapid effusion and removal of it in states of rest suggest the probability of a circulation between the blood and the tissue spaces—a circulation independent of the lymphatic circulation. 3. The apparent physiologic intent of the effusion is reparative, and that of its absorption is the removal of tissue waste. 4. The normal intermittency of the fluid exchange becomes in many pathlogic conditions less and less complete. By studying the conditions which increase or decrease lymph effusion we ought to gain a clearer insight how to control derangements of nutrition and metabolism.

25 A Review of Some Recent Observations on Gastric Affections. H. D. Rolleston.
26 Seborrhea and the Seborrhoides: A Review of Some Recent Literature on Skin Diseases. J. M. H. MacLeod.

21. **Retroversion of the Uterus.**—Eden concludes that backward displacement of the uterus frequently gives rise to no symptoms and requires no treatment, but where symptoms are caused, complications are usually present, either consecutively or independent. Before beginning treatment the question whether the symptoms are hysterical should carefully be considered. The pessary should only be adopted as a temporary measure or in "simple" cases; it rarely cures. Local depletion is a valuable adjunct to treatment by pessaries. Cases unsuitable for treatment by pessaries or where they have failed to relieve, should be advised to undergo ventrofixation. The method of performing this operation that he recommends is not that of Kelly. The suture, he thinks, should be placed as low down as possible on the anterior uterine wall, avoiding the bladder below and coming short of the fundus above, thus apposing a broad surface to the abdominal wall and allowing the development of the uterus in subsequent pregnancies.

23. **The Nucleus in Malignant Neoplasms.**—Paterson has observed in a number of carcinomata the nuclei throwing out processes like pseudopodia, these sometimes forming the first stage of daughter cells by budding, but in others are the beginning of the migration of the nucleus from its cell, either to an adherent cell or in the surrounding fibrous tissue, or it may produce a daughter nucleus, and become the center of a new cell formation, or may coalesce with another similar nucleus. Sometimes several nuclei fuse, and thus a large mass of nuclear matter is found, from which daughter nuclei are set free by budding or fission. Coincident with these, others are proliferating by mitosis with a diminished number of chromatin filaments. The processes observed are primarily analogous to the formation of polar bodies and the union of sexual elements, but the resulting nuclei are only able to reproduce cells similar to those from which they originated. The phenomenon can be observed more or less throughout the tumor mass, but a proliferation by budding is more notable near the periphery and mitosis toward the center of the tumor. He explains the metastasis by nuclei which have undergone this change and possess this power, having been transferred to other parts and repeating the process in other situations. As to the exciting cause of this alteration of nuclei he is non-committal.

24. **Malignant Character of Apparently Benign Ovarian Cysts.**—*From a consideration of the cases* here published and others, Taylor concludes that:

> 1. It is impossible by mere macroscopic examination to distinguish between benign and *malignant ovarian cysts.* Every ovarian cyst should be submitted to microscopic examination to determine its precise nature and give accuracy and precision both to diagnosis and prognosis. 2. Every ovarian cyst should be submitted to operation and removed with the least possible delay after its discovery, because of the uncertainty of its nature. 3. Ovarian cysts should invariably be removed entire, without being tapped or punctured, the abdominal incisi to the necessary extent. The risk of *sowing* oadcast and implanting them on the peritoneal may proliferate luxuriantly, is *thereby avoided.* 4. During the *operation* of ovariotomy the ovarian pedicle should be ligatured and cut through as near the uterus—that is to say, as far away from the diseased tissues—as possible. Nothing in the nature of conservative surgery is permissible in dealing with ovarian cysts.

30. **Extraction of Pin from Bronchial Tube.**—A young woman aspirated a steel pin with a glass head, and all attempts to remove it from the air passages failed. Three months later Killian's bronchoscope was introduced through a tracheotomy opening and the pin was seen in a bronchial tube of the third order, the point upward. It could not be dislodged with the magnet, but it was seized with the forceps through the bronchoscope and drawn out with it. The grasp of the forceps was relaxed as the head of the pin was brought outside the wound, when a deep inspiration drew it in once more, and a second introduction of the bronchoscope and forceps was necessary for its final extraction. Three attempts to introduce the bronchoscope through the tracheotomy opening had been made during the month preceding this successful intervention, but a reflex arresting the respiration occurred each time and compelled the postponement of the operation. This is the second case published in France of the successful use of the bronchoscope.

31. **Miners' Anemia.**—Fabre's views are the crystallized conclusions of thirty-two years of practice among miners. He has already published sixteen communications on the hygiene and pathology of miners, some of which were read at congresses. He thinks the term "miners' anemia" is misleading, as miners are not subject to any special form of anemia. They are, however, exceptionally exposed to causes which tend to impoverish the blood. These causes are both general and professional, and besides these there are predisposing influences, individual or congenital, or acquired from defective hygiene, excesses of all kinds, inadequate food, unhealthy houses, and the pathologic anemia from preceding chronic affections, rheumatism or the presence of helminths, tapeworm, ascarides or ankylostoma. He has never observed but a single case of ankylostomiasis. Prophylaxis should consist in supplying fresh air to the miners when at work, in individual hygiene and suitable nourishment, avoiding excesses and overexertion of

all kinds and prevention of accidents. In the discussion that followed it was stated that the assertions that France was free from ankylostomiasis had been disproved by Calmette's recent investigations. A committee was appointed, composed of Laveran, Blanchard, Chantemesse and Roux, to study the subject.

32. **Round Worms as Cause of Disease in the Tropics.**—Kermorgant gives the details of 10 cases reported from various parts of the French colonies, in which the ascaris lumbricoides caused a vague febrile state or complicated typhoid or other diseases. In several instances the worms caused serious lesions in the intestines, obstruction or perforations in some cases, or by finding their way into the liver or biliary passages induced abscess formation. In one case these parasites were found in the intestines, stomach and one ventricle. As diluted feces are used to fertilize vegetables, Europeans as well as the natives are subject to this "lumbricosis," as he calls it, which is very liable to be mistaken for malaria.

33. **Local Cocain in Abdominal Surgery.**—This and the following article are published only by title in the *Bulletin*, but our Paris exchanges of the same date, April 20, give abstracts of them. Chaput reported that he has performed twenty-five major operations on the abdomen with local cocain anesthesia alone. The list includes ovariotomies, gastroenterostomies, hysterectomies, appendicectomies, etc. If the subject is timid and general anesthesia has to be induced after all, the previous use of the cocain does not interfere with it in any way.

34. **Ovarian Castration in Inoperable Cases of Cancer of the Breast.**—Reynès presented a patient, 33 years old, whose breasts showed a slight cicatricial thickening and induration. A year before she had a large ulcerating and inoperable epithelioma on each breast and was already cachectic. One of the tumors had been developing for nine years, the other for three. He removed both ovaries and the tumors began to retrogress at once. In two months one had entirely healed over, and the other soon followed. A similar result has been observed in another case, in which the tumors are rapidly retrogressing. The physiologic relations between the ovaries and the breasts explain the influence of castration in these cases, but of course this influence would not be appreciable outside of the period of full sexual activity.

Semaine Médicale, Paris.

35 (XXIV, No. 17.) *La tuberculose intestinale comme cause d'invagination. L. Bérard.

35. **Tuberculosis as Cause of Invagination.**—Five cases have been published and Bérard has had occasion to observe 2 more, in which a tuberculous affection of the intestines induced invagination. Four of these 7 cases were in children, and he refers to the remarkable recuperative power of children as an argument against very radical intervention in such conditions. He has had a patient with multiple tuberculous strictures in the intestine recover complete health after a mere laparotomy with detachment of a few adhesions. Nothing was done to the six strictures that could be observed in the ileum, and they have all retrogressed since. Other French writers have published cases of recovery from hypertrophic tuberculosis of the cecum after mere laparotomy. If the tuberculous affection is not very extensive nor the stenosis very pronounced, simple reduction of the invagination with ileo-cecopexy is liable to be followed by a complete cure. One of his patients died, the other recovered after this intervention. The symptoms in the latter case had been attacks of colic, followed by vomiting of greenish matter, the maximum of pains around the umbilicus. These symptoms subsided after a week, leaving dull pains and tenacious diarrhea with traces of blood in the stools. Palpation the third week revealed a zone of tenderness, resembling a patch of inflammation of the omentum, most pronounced when the rectus muscles were most relaxed. There was also resistance to pressure, most marked toward the right iliac fossa, but not painful. Temperature normal.

36. **Anastomosis of Vas Deferens.**—The Journal has previously referred to the successful anastomosis of the vas deferens in Razumowsky's experimental research on large animals. The technic which offers the greatest advantages is the establishment of anastomosis between the vas deferens and the head of the epididymis or the upper half of the body of the epididymis. The permeability of the passage is soon restored, the anastomosis in some cases allowing the passage of sperma.

37. **The Facial Nerve in Surgery.**—In operating in the region innervated by the facial every effort must be made to avoid injury of the ramus maximus marginalis mandibulæ and of the rami zygomatico temporalis. In case injury of the latter is unavoidable the middle of the zygomatic arch and the region of the eyebrow and to the middle of the arch must be avoided, as here run the principal nerves for the upper part of the M. orbicularis oculi, and also for the M. corrugator supercilii, which it is particularly important to leave intact. The ramus collo mandibularis is comparatively unimportant, as it is inconstant and as, besides, it is not the only nerve that supplies the muscles of the lower lip. The anatomic conditions are shown in a number of diagrams and some of the various surgical modes of technic are illustrated.

38. **Urinary Calculi Below the Prostate.**—Englisch devotes several pages to a compilation of the literature on the subject of stones impacted in the urethra or in a diverticulum from it, a total of 405 cases. He classifies them in various groups and discusses each in turn. In 5 instances the subject was less than a year old; in 23 less than 2 years; in 92 under 10; in 35 between 10 and 15; in 22 between 16 and 20; in 41 between 20 and 30; in 39 between 30 and 40; in 81 the age was not mentioned. The stones were in the pars membranacea in 149 and in the pars bulbosa in 68.

40. **Volvulus and Ileus from Movability of Ascending Colon.**—Ekehorn classifies in five groups the large number of instances of this condition which he cites from his own and the experience of others. He discusses the particular features which distinguish the clinical course of each group.

41. **Remote Results of Uranoplasty.**—The results in the 105 cases reported from von Eiselberg's clinic at Vienna were least satisfactory in the children under 2 years old. The 4 deaths that occurred in the 105 cases were also of children under 2. The different technical methods followed are described in detail with the remote results. Systematic exercises to train the voice were of great importance for the final functional result. Normal speech was regained in only 6 of the 64 followed to date. In 44, or 68.75 *per cent.*, the speech was very much improved, but still had a nasal ring, and in 14, or 21.87 per cent., there had been no functional improvement. The anatomic closure was complete in 41.58 per cent. of the total number operated on, and nearly complete in 27.72 per cent.

43. **Practical Tendon Suture.**—A number of advantages are attributed to the method of suturing the tendon here described. A thread is passed through the stump, first forming a narrow U and then an X, the ends then brought together and tied, which gives a remarkably firm hold on the tendon. The two stumps are then tied together, side by side, with these threads,

the stumps overlapping 3 to 4 mm. They grow together, and the constant traction finally pulls them into a nearly straight line, the right-angled outer corner of each cut surface dragged into an angle of about 140 degrees, thus forming nearly a straight line. Experiments on dogs and in 2 clinical cases confirm the complete restitution of the tendon.

48. **Acid Cure of Pruritus.**—Köhler relates that a distressing pruritus in a subject with incipient tuberculosis was cured in five days under the influence of a tablespoonful every two hours of a 3/200 solution of sulphuric acid.

51. *Acute Articular Rheumatism.—Burwinkel does not regard* salicylic medication as an advance in the treatment of articular rheumatism. He prefers to *treat it by* repose, *mild hydriatic* procedures and repeated venesection, withdrawing 150 to 300 c.c. of blood at a time.

52. **Subcutaneous Feeding in Surgery.**—Friedrich's later experiences have fully confirmed his previous announcements in regard to the great value of subcutaneous feeding in certain severe *gastrointestinal disturbances, in which feeding by the* mouth or rectum and also a fistula are contraindicated. His *technic is the* daily *injection* of 40 to 100 gm. of grape sugar in a 3, 4 or 5 per cent. solution. He also uses a pure pepsin-peptone, free from albumoses (the chemically pure product being made according to the method devised by Professor Siegfried of the Leipsic Physiologic Institute). Twenty grams of this combination injected subcutaneously are completely utilized by the organism. He gives it in a 7 per cent. solution, with or without the grape sugar. An admirable combination is .2 gm. table salt; 2 g. grape sugar and 4 gm. pepsin-peptone to the 100 gm. water. With this subcutaneous nourishment he has been able to tide patients past the critical period of perforation of the stomach or bowel, or severe peritonitis from any cause.

55. **Organ Treatment of Pancreas Affections.**—A man of 52 was under observation in Ewald's service for several months, the differential diagnosis of his sickness being some affection of the pancreas. The diagnosis was based on the presence of pancreas colics, alimentary glycosuria, fat in stools and impaired digestion of albumin. Administration of thyreoidin had an unfavorable effect. Pancreon displayed a slight influence on the absorption of nitrogen, but none on the absorption of fats. The administration of pancreatin (Rhenania) proved distinctly beneficial. The absorption of nitrogen increased from 52.2 per cent. to 65.7 per cent. and of fats from 40.9 per cent. to 68.5. Alkalines alone caused only a slight improvement in the utilization of nitrogen and fats, but the combination of pancreatin and sodium bicarbonate produced the best effect of all. Five .25 *gm.* doses of the pancreatin were given during the day accompanied by 30 gm. of sodium bicarbonate, and the absorption of nitrogen increased from 53.1 per cent. to 62 per cent. and of fat from 37.9 per cent. to 69.8 per cent. A number of cases which presented similar symptoms, fatty stools and alimentary glycosuria, have been treated in the same way since, but no benefit was apparent. The postmortem findings in each case disclosed that the trouble had been due merely to isolated atrophy of the small intestine. Consequently the success of organ treatment in cases presenting this syndrome may serve to differentiate pancreatic from other affections. The former are not so rare as generally supposed.

56. **Sinusoidal Alternating Current *in Therapeutics.***—Lippert found in his research in this line with 149 observations that the electric baths with the sinusoidal alternating current had a marked effect in increasing the blood pressure, while generally diminishing the pulse rate. This form of electricity has also a stimulating action on the metabolism and on the energy of the heart and other musculature. It also promotes sleep. This effect was unmistakable in cases of arteriosclerosis and in some of simple neurasthenia. French writers have announced that it is beneficial in gynecology.

57. **Has the Campaign Against Tuberculosis Accomplished Anything?**—Ascher marshals the statistics gathered in Prussia, and points out that the decline of the tuberculosis death rate is made up by the increased mortality from acute respiratory affections. The decline in the mortality from both these causes in the German cities with a population of more than 15,000 is misleading, as no account is taken of the influx of population from outside. The decline in the death-rate from tuberculosis had begun before the tubercle bacillus was discovered, and it is greater in the circles in which no efforts have been made to combat tuberculosis than in the country at large. The average age at death of consumptives is growing constantly lower. This fact he attributes to increasing industrializing and crowding of the populace. The increase in the mortality of acute respiratory affections is mainly in children. *It may be regarded as a disturbance in the* balance between the bacteria normally present in the air passages and the resisting *forces of the organism.* His researches have convinced him that climatic influences are not an essential factor. He also cites statistics to show that the mortality from infectious diseases is greatest in the country, less in the small towns and least in the cities, while the mortality from respiratory affections and also from congenital debility and atrophy are in inverse proportion. Among the incomprehensible statistics which he cites is the comparative mortality of nurslings from respiratory affections as given in the statistics of typical districts, one a farming region, *one a* manufacturing center in Silesia and another in a Rhine province. The increase *in the mortality from this cause in* nurslings has been constant, in the farming district it has been 83 per cent.; *in* Silesia, 460 *per cent.*, and in the Rhine district, 470 per cent., the figures in the Rhine province being 36.9, 66.1, 122.3, 153.4 and 167—212 per 10,000 inhabitants in the consecutive five-year periods since 1875. There has been no such increase in the mortality from congenital debility and atrophy, consequently accessory causes must be sought, as there are no grounds for assuming a predisposition of this nature. He ascribes to the present faulty methods of hygienic and statistical investigation the fact that this almost incredible increase in the death rate has escaped general attention hitherto. Some of his statistics are derived from MSS. in the archives of the Prussian Bureau of Statistics, the percentages first computed for this article. The first part was published in the *Wochenschrift* last year, No. 44. 1903.

58a. **Fate of Compresses Left in Abdomen.**—Riese had occasion to observe a case simulating an ovarian tumor which proved to be a perfectly encysted foreign body, a compress left from some preceding intervention. He experimented on dogs and found that compresses left in the abdomen might have this fate or might *work their* way into the intestine and be expelled.

58b. **Artificial Gangrene in Gastrointestinal Operations.**—Wullstein makes an anastomosis between *stomach* and intestines, between intestine and gall bladder, etc., by invaginating the parts and inducing *gangrene by mechanical* or thermic irritation or cauterization with carbolic acid. By this means he can perform *gastroenterostomy* without assistance or any hemorrhage, and in thirty hours have the part involved duly excluded.

58c **Bladder Tumors in Anilin Workers.**—Rehn has observed 21 cases of tumors in the bladder among workmen employed in anilin works for five to twenty-nine years. In 3 instances it was a papilloma, but in the 18 others it was either a sarcoma or carcinoma. Eleven of the patients have already died. He urges others to seek for and publish such cases.

74 *A Study of the Disinfectant Action of Hypochlorous Acid with Remarks on Its Practical Action. F W Andrewes and K J P Orton (London). (Concluded.)

74 **Powerful Disinfectant Action of Hypochlorous Acid.**—The germicidal power of pure hypochlorous acid, in absence of organic matter, is of the most intense kind. Fully exposed anthrax spores are killed by a 0.01 per cent. solution in one minute. In a strength of 0.001 per cent. it kills the *Staphylococcus aureus* in one minute and the colon bacillus in a strength of 0.0004 per cent. In presence of organic matter it is comparatively inert. A combination of hydrochloric acid with ammonium persulphate for an oxidizing agent, has proved fully the equal of Krönig and Paul's potassium permanganate hydrochloric acid germicide, while it is more stable and free from the disagreeable staining properties of the latter. In presence of a moderate amount of organic matter it is actually superior to the permanganate mixture. The writers commend the new combination as especially valuable for skin disinfection and sterilization of sponges. The formula is a 3.7 per cent. solution of ammonium sulphate mixed with 1 per cent. of strong aqueous HCl and kept for a few days. The formula for the permanganate mixture is potassium permanganate, 1 gm., HCl aq. fort. 1.1 c.c. in 98 c.c. distilled water. The parallel formula of the new mixture is ammonium persulphate 3.7 gm., HCl aq. fort. 1.1 c.c. and 95 c.c. distilled water. The disinfectant properties of various preparations of chlorin are probably due to their hypochlorous acid content. The above mixtures are much more powerful than corresponding strengths of sublimate.

80 *Experiences in Life Insurance. Guttstadt.—Erfahrungen der Lebensversicherung.
81 Report of German Congress of Surgery April 4-9, 1904. See ¶ 58.

76 **Principles of Treatment of Short Sight.**—Sattler sets forth the urgent necessity for complete and lasting correction of even slight degrees of short sight. He reviews his long experience at the Leipsic Ophthalmic Clinic and the lessons learned thereby.

78 **Principles of Treatment of Infectious Diseases at Leipsic.**—Soltmann describes the measures used at the clinic for children's diseases. The little patient is isolated and the other children in the family are not allowed to attend school until the patient is entirely well and past the contagious stage, after three weeks in case of measles, six weeks in scarlet fever, four weeks in diphtheria, and in pertussis after all paroxysms have subsided. One to three baths are given daily, according to the severity of the case, from the first day in scarlet fever, with commencing desquamation in measles, and in the other diseases cautiously according to the individual case. Sweating baths and copious sweats are advocated in scarlet fever. The children are kept in bed for three weeks in case of measles, and six weeks in case of scarlet fever. The diet is mainly milk, milk gruels, and milk dishes of all kinds, gelatin soups, cocoa, etc. The special measures for each of these diseases are described in detail.

79 **Influence of Radiation on Cell Segmentation.**—Perthes exposed large numbers of the fertilized ova of *Ascaris megalocephala* to the x and radium rays. He found that their results were identical in kind, each causing the ovum to develop into an imperfect, abnormal embryo. The same effect on cell segmentation was observed in plant cells. The phenomena observed indicate that the rays induce the formation of substances in the living cell which in turn injure the chromatin of the nucleus.

80 **Life Insurance Experiences.**—The Gotha Life Insurance Company or "Bank," has recently published its experiences during seventy-five years of existence. The volume is edited by Karup, Gollmer and Florschutz. Among other points they proclaim that they have learned that the copper and bismuth tests for sugar in the urine are worthless unless they give an absolutely negative result. The phenylhydrazin test is unreliable unless supplemented by the microscope, in which case it is exact and reliable.

82 **Experiences with Iodoform Filling for Bone Cavities.**—Some American writers have already adopted the German term for the Mosetig procedure—"plombierung." It has been fully described in THE JOURNAL and its value as set forth by various writers as, for instance, on page 1506 of the last volume. In this article Mosetig definitely describes his perfected technic, with numerous illustrations, and reviews the experiences of five years with it. The details are given of 79 cases of osteomyelitic affections thus treated, also of 108 tuberculous affections and of 8 others (in 2 plugging the antrum of Highmore, and in 4 plugging dental cysts.) The youngest patient was under 3, the oldest 76. Not a single mishap occurred in any instance. In a few cases of osteomyelitis of the tibia the entire diaphysis had to be removed, and its place was filled with the iodoform filling. One of these patients, a girl of 12, passed through pneumonia the next month and erysipelas six weeks after this but rapidly recuperated to complete recovery with no signs of injury from the enormous quantity of the iodoform injected. The iodoform does not become absorbed until its particles are reached by the new growth of bone tis

sue through the filling, consequently absorption proceeds very slowly. The only indispensable is that the cavity to be filled must extend into sound tissue and be absolutely free from all morbid tissue and germs. The radiograms appended show how the filling constantly diminishes in size until after a year not a trace of it can be detected.

83. **Central Luxation of Hip Joint.**—By this term Arreger means the displacement of the head of the femur through a fracture of the acetabulum, the impact on the trochanter driving the head into the pelvis through the acetabulum. Such accidents are rare, but may be surmised when the limb is found in outward rotation, and reduction is easy and generally painless, but the displacement gradually recurs so soon as the parts are released. Another sign is the shortening of the distance between the symphysis and trochanter and likewise the presence of an experitoneal hematoma, and the protrusion of the head of the femur and the fragments into the small pelvis. The diagnosis is confirmed by intra-abdominal examination through the vagina or rectum and radiography. On account of possible simultaneous injury to bladder and intestines the physical examination must be done cautiously. In mild cases properly treated a new joint develops inside the pelvis from the fragments of the acetabulum, forming a new cap for the head of the femur. Healing is necessarily the work of several months and there is always more or less functional incapacity. In severe cases the accident is always speedily fatal from shock, sepsis or injury of the intestines. Treatment should consist in lateral and lengthwise extension or an immobilizing cast reaching above the costal arch, after reduction. The new acetabulum that formed from the relics of the old was unmistakably apparent in 5 out of the 7 cases of survival on record, and its formation may be accepted as the rule. All the other cases died out of the 23 known of this accident. His bibliography contains no American references. (See Wilms below, ¶88.)

84. **Achilles Tendon Covering for Stumps.**—Dietel gives a photograph of one of the 9 cases treated by utilizing this tendon to cover the stump after amputation of the tibia. The lad is standing on his stump, the other foot raised, as securely as he could stand on the sound foot, and the limb is not so much shortened as by other methods. Other cuts show the details of the technic.

85. **Ablation of Tumors in Pelvis.**—Zeller gives the particulars of a case of fibro-sarcoma-myxomatous-cystic tumor successfully removed from the right sacro-iliac synchondrosis. The patient was a woman of 38, and she has been in good health during the two years since, with no signs of recurrence. He also analyzes the cases on record, including a few from America. The list includes 5 of fibroma, 3 of exostosis, 10 of enchondroma, 3 of sarcoma or a mixed tumor—all the above group pedunculated or easily shelled out. In a second group of broad-based tumors requiring extensive resection of the pelvis, he reviews 6 cases of enchondroma and 31 of sarcoma or a mixed growth. He thinks success depends on early intervention. After cachexia has developed the prospects are much less promising.

87. **Esophagoscopy.**—Hartmann gives a number of the views obtained by esophagoscopy. He prefers the stiff Mikulicz esophagoscope with the Caspar electroscope as the most convenient combination for the purpose.

88. **Central Luxation of Head of Femur.**—Wilms writes that he has seen 4 patients with this accident within three years. All recovered, but as none would submit to proper treatment all were more or less crippled in the use of the leg. The joint became rigid; rotation and abduction were more interfered with than adduction and flexion. All but one find long continued walking painful. Theoretically speaking, he would prefer to reduce the head by flexing the hip joint with slight adduction rather than by mere extension. The position he advocates would prevent redisplacement, by the contact of the shaft against the anterior ring of the pelvis. In one of his cases extension was unable to reduce the head, but flexing the joint with slight adduction easily restored it to its normal place.

93. **Relations Between Trigeminal Neuralgia and Corneal Erosions.**—Bartels relates two typical cases in which an erosion of the cornea was followed by recurring attacks of inflammation. Both patients were subject to trigeminal neuralgia. Study of the cases showed that the recurrence of the corneal irritation was due to the trigeminal affection, and after months of ineffectual treatment of the eye, by addressing treatment to the neuralgia, both patients were promptly and permanently cured. His mode of treating neuralgia is by salicylic medication supplemented by continuous application of linseed poultices to the emerging point of the nerve, and strict repose in bed; the course of treatment ranging from three to eight days, according to the severity of the case. He has found pyramidon useful as an analgesic and also injection of Schleich's No. 2 solution at the emerging point of the nerve to arrest very severe attacks. He advised his patients to carry a salicylate powder constantly with them, to take at the first recurrence of the neuralgia and thus ward off the secondary corneal lesion, but neither has had a recurrence to date.

95. **Prognosis of Sarcoma of Small Intestine.**—Steinthal states that 18 out of the 45 patients with this affection on record were treated by operation and 10 recovered, but nothing is known as to the further fate of 7; Hahn's patient is still living after eight years and Steinthal's 2 patients are both in good health, one three and the other four years after the intervention. The records show that the spindle-celled sarcoma entails stenosis of the intestines very early and thus surgical intervention is sought at an earlier stage than with other forms One of his cases was a sarcoma of this kind and the other a small-celled, round-celled sarcoma. Both induced stenosis early; the growth was single, and there was no tendency to breaking down. The prognosis of this class of cases is, therefore, less somber than hitherto supposed. An attentive examiner may discover a malignant tumor in the small intestine before it ulcerates and entails secondary dilatation of the intestine.

96. **Sodium Phenyl Propylate in Tuberculosis.**—Löw pointed out a while ago that as cinnamic acid is more bactericidal than phenyl-propylic acid, and as the only difference between their chemical composition is that the cinnamic acid has two atoms less of hydrogen, it follows that by extracting two more atoms of hydrogen the resulting substance would be even more strongly bactericidal. Bulling has been testing this theoretical reasoning in practice, and has found that the premises are correct, and that the third substance—which is a sodium phenyl-propylate—is much stronger in its bactericidal effect than either of the others. His experience compels him to announce that the success obtained with it in treatment of tuberculosis of the lungs and larynx was so striking that it should be given a trial in every case that is not absolutely hopeless

when first seen. He gives the particulars of three cases, and describes his mode of employing the propylate in half-hour inhalations twice a day. The patient places the mouthpiece of the atomizer on his tongue and breathes regularly as usual, without effort. The temperature of the spray is gradually increased from 77 to 86 F. at first to 108 or 109 and in case of a tendency to hemoptysis to 113 F. This heat from the spray induces a passive hyperemia of the air passages which enhances the bactericidal action of the drug. The last few minutes of the inhalation the temperature is reduced again to about 95. After the inhalation the patient keeps still and does not speak for an hour. He gradually increased the strength of the solution to 3 per cent., which he now uses exclusively. The cases described were thus treated for one or two months or longer.

100. The Stuttgart Diet Discussions.—For a number of months the physicians of Stuttgart have been engaged on the task of preparing a set of rules for the diet in various diseases. It is the first time that a German medical society has devoted its sessions to discussion of this subject, and three five-hour sessions have resulted in the adoption of a set of rules which will soon be published. They are intended mainly for the working classes.

102. Functional Diagnosis of Arteriosclerosis and Differentiation of Angina Pectoris.—Sihle describes extensive research on the blood pressure undertaken by applying the Riva-Rocci apparatus to the brachial artery, the Basch sphygmomanometer to the radial and the Gaertner tonometer to the digital. He made 1,500 different tests on 600 healthy subjects and established the physiologic range of the brachial pressure as 120 to 150 mm. mercury for healthy subjects, while the radial range is from 100 to 140 and the digital from 90 to 110. He did not find the Basch apparatus as reliable as the others. The difference between the brachial and the digital pressure on the same subject was seldom more than 50 mm. In a large number of healthy subjects between 15 and 35 years old the minimal difference was 25 to 20 mm. The difference was greater under the influence of an emotion. In some instances the neuro-muscular apparatus of the vessel walls showed great instability in respect to the influence of emotions. As age encroaches the difference between the pressure in these different arteries increases. The resistance to the passage of the blood is augmenting, the vascular tube becoming stiffer, and a large difference indicates pronounced arteriosclerosis. He announces that the development of sclerous degeneration of the vessels is preceded by a stage in which there is merely enhanced tension of the vessel walls. This early stage of arteriosclerosis has hitherto been beyond the reach of our diagnostic measures, but it is easily detected by this method of combined comparative examination with the Riva-Rocci sphygmomanometer and Gaertner's tonometer, comparing the difference between the findings with the standards established for the normal pressure in the brachial and the digital arteries. This mode of examination not only notes the degree of tension of the vessel walls and the resistance to the circulation offered by the vessel, but it also gives reliable information in regard to the heart action. The stiffer and narrower the vessel, that is, the more advanced the arteriosclerotic process, the greater the difference between the blood pressure findings at these arteries, provided the heart action is still unimpaired. The more relaxed, that is, hypotonic, the vessel wall and the lesser the resistance, the lower the blood pressure and consequently the smaller the difference between the pressure at the brachial and digital. The mean difference between the brachial and digital arteries in middle-aged subjects averages 30 to 40 mm. mercury. When this difference in pressure is permanently 60 mm. or over it positively indicates a sclerotic process. Sclerosis in the arms premises sclerosis in the internal organs also. On the other hand, a normal or subnormal blood pressure in the vessels of the arms with a normal or subnormal "pressure difference" are presumptive evidence against sclerosis of the internal organs. Knowledge of the conditions of arterial pressure and especially of the "pressure difference" is important also in regard to differentiation and prognosis of angina pectoris. He regards this as essentially a reflex neurosis. The radiating pains are principally due to spasm of the vessels. Arteriosclerosis and infectious diseases, la grippe for instance, afford particularly favorable conditions for the development of this neurosis.

105. Gussenbauer Festschrift.—A number of works on clinical surgery by pupils of Karl Gussenbauer were collected and illustrated in this *Festschrift* in honor of his sixtieth birthday, but his untimely death renders the volume a memorial. Exner's article on "Sharp Foreign Bodies in Digestive Tract" states that in 154 cases of needles or nails in the digestive tract only 28 terminated fatally, and in only 20 of these was the death due unmistakably to the foreign body. In 35 cases of pieces of glass 22 were passed without having caused trouble. His statistics include only foreign bodies less than 10 cm. in length. He has established a certain protecting mechanism in the alimentary canal against sharp foreign bodies. Büdinger concludes from his experience with 7 cases of tuberculosis of the pubic symphysis that radical extirpation is the only promising treatment, but that this is inapplicable in the more extensive cases. Narath's study of "Congenital Luxation of the Hip Joint" is based on 150 cases followed for years. He advocates firm fixation with abduction to at least 90 degrees and rotation outward during the first cast period—three months. He describes certain modifications of the reduction procedures which have proved useful in his hands.

106. Serum Treatment of Puerperal Fever.—Peham relates that the experiences at Chrobak's clinic with Marmorek's serum were not favorable, but that Paltauf's antistreptococcus serum has shown an unmistakably beneficial action. It is derived from horses inoculated directly with fresh streptococcus cultures from puerperal processes and other severe streptococcus infections in man, with no passage through animals. Twenty-six cases of puerperal infection were injected with the Paltauf serum and all those patients with pure streptococcus infection rapidly recovered, including one case of puerperal peritonitis In the cases in which no benefit was apparent bacteriologic investigation showed that the infection was due solely to the colon bacillus or pneumonia germ.

109. Dosage in Radiotherapy.—On page 804 THE JOURNAL recently described some of the devices presented for this purpose. Freund proposes a radiometer based on the chemical power of the rays to liberate iodin in a solution. He uses a 2 per cent. chloroform solution of iodin, which retains its color in the dark but changes its tint rapidly under the influence of the *x*-rays. This change in tint is a purely chemical oxidizing process capable of mathematical demonstration. Test tubes 1 cm. in diameter are filled with 5 c.c. of the solution and after six minutes of exposure to a medium soft Röntgen tube—an intensity corresponding to that required for fluoroscopy of the thorax of an adult at a distance of 1.5 meters —he found that .59 mg. iodin were liberated. This imparted a distinct purplish tint to the fluid. Twelve minutes under the

same conditions liberated exactly twice this amount of iodin and eighteen minutes exactly three times the amount. He accepts the above as the unit for comparison. For weaker applications of the *x*-rays he accepts .35 mg. iodin per 5 c.c. of the solution as the standard unit. The test tube is wrapped in black paper and placed on one side of the exposed area.

110. **Cure of Tuberculosis of Kidneys and Bladder.**—Kapsammer's 5 cases show that the freezing-point of the urine is liable to be influenced by reflex polyuria from catheterization of the ureters, and consequently the findings should be read with due caution. In one of his cases there was .5 per 1,000 albumin, while the freezing-point of the urine was —.52 C. and of the blood —.58 C. Notwithstanding these findings he performed nephrectomy; the albumin vanished at once from the urine and the patient soon regained her health. He urges the importance of catheterizing both ureters in establishing the diagnosis, and he always uses the phloridzin and methylene blue functional tests besides. In one of his cases local treatment with sublimate and guaiacol-iodoform cured the extensive tuberculous affection of the bladder while waiting for the nephrectomy. In another case he found it necessary to remove the entire ureter, and in 3 others 18 cm. of it. In one case the ureter was extensively involved while there was only a single small cavity in the kidney. The pelvis of the kidney was dilated and contained 40 c.c. of pure urine with a few flakes of pus; the ureter orifice was obstructed by a tuberculous ulceration evidently due to passage of pus from the cavity. This had in turn induced stenosis, stagnation of urine, uronephrosis and consequent tuberculous pyonephrosis. His experience has convinced him that it is not necessary that the kidney to be left should be absolutely sound. It rapidly recuperates after removal of its diseased mate.

115. **The Brain and Syphilis.**—In the conclusion of this summary of our knowledge on this subject Hirschl mentions that syphilis was not introduced into Bosnia and the South Sea Islands until comparatively recently. The lesions presented by the inhabitants to-day correspond to those observed in Europe at the beginning of the second century of syphilization, that is, about A. D. 1600.

116. **Treatment of Chronic Arthritis with Injection of Vaselin.**—Büdinger lubricates the parts of inflamed joints by injection of sterile vaselin. In mild, chronic cases the results are good in all and sometimes prove very fine. In severe, chronic arthritis considerable improvement is realized in many instances, and in old, inveterate processes in the joints the vaselin proves a valuable adjuvant to other therapeutic measures. These injections certainly accomplish more in several directions than any other mode of treatment. Of course they should not be attempted in a tuberculous process nor in acute exacerbations nor in gonorrheal affections until a long interval after the acute phase. He uses white or yellow vaselin, warmed, preferring the latter, injecting 1 to 2 c.c. in small joints, 3 c.c. in the shoulder and 4 c.c. in the knee. After the injection he manipulates and moves the joint to bring the vaselin in contact with the parts. There is usually considerable pain after the injection, gradually subsiding in two to six days. Sometimes a feeling of numbness is experienced or indications of slight synovitis are noticed, but the benefit from the injections is soon apparent and has been permanent to date. He explains their action as the filling up of unevennesses which maintain irritation or cause pain on movement. The consistency of the vaselin prevents its absorption. In one case he opened the joint forty days after injection of 4.5 c.c. of vaselin and examined a fifth of the fluid accumulated in the joint, finding exactly one-fifth of the amount of vaselin that had been injected. He gives in detail the particulars of the 15 cases thus treated to date, the first dating from July, 1903. One of the great advantages of this treatment is that as the function of the joint is improved the resulting atrophy of the muscles improves with it or its occurrence is prevented.

117. **Diagnosis of Hip-Joint Disease.**—Friedländer shows by four examples that the characteristic attitude assumed from the first by the subject varies with the exact location of the lesion. The partial restriction of the conical excursions of the limb involved is also a differential sign, and the initial limitation of movability in a certain direction. In one case the leg was apparently lengthened, slightly flexed and slightly rotated outwards. Flexion, adduction and outward rotation were unimpeded, but extension, abduction and inward rotation caused pain. Radioscopy showed a focus in the joint at the edge of the epiphysis, involving the neck of the femur. The course of the blood vessels renders extension of the process to the head almost inevitable, and he consequently excised the focus. The operation confirmed his assumption of an embolic focus with backward infection of the soft parts. A focus in the other leg had been extirpated previously. In his other cases it was impossible to extend the hip joint or abduct it, while adduction and inward rotation were unimpaired. The foci in these cases were at the insertion of the capsule in the lower circumference of the neck.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE JOHN CRERAR LIBRARY. Ninth Annual Report. For the Year 1903. Paper. Pp. 52. Chicago: Printed by Order of Board of Trustees. 1904.

PROCEEDINGS OF THE EIGHTEENTH ANNUAL MEETING OF THE CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH OF NORTH AMERICA. Baltimore, Oct. 23 and 24, 1903. Paper. Pp. 84. Providence: Snow and Farnham. 1903.

ROENTGEN RAY DIAGNOSIS AND THERAPY. By Carl Beck, M.D. Professor of Surgery in the New York Post-graduate Medical School and Hospital. With 322 Illustrations in the Text. Cloth. Pp. 460. Price, $4.00. New York and London: D. Appleton & Co. 1904.

MATERIA MEDICA, PHARMACOLOGY AND THERAPEUTICS. Inorganic Substances. By Charles D. F. Phillips, M.D., LL.D. (Abdn and Edin.), F.R.S., and F.R.C.S. (Edin.). Third Edition. Cloth Pp. 921. New York, London and Bombay: Longmans, Green & Co. 1904.

PROCEEDINGS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION at the Fifty-first Annual Meeting, Held at Mackinac Island, Mich. August, 1903: Also the Constitution and By-laws and Roll of Members. Cloth. Pp. 1103. Baltimore: Published by the American Pharmaceutical Association. 1903.

NEW PATENTS.

Patents issued from April 19 to May 10 of interest to physicians:

758030.	Nasal shield. Thomas Carence, Kansas City, Mo.
757806.	Disinfecting apparatus. Albert Giersiepen, Remscheid, Germany.
757654.	Syringe. Henry M. Guild, deceased, Erie, Pa., N. J. Maxwell, executor, New York.
757807.	Physicians' examining and treating couch or table Charles C. Hazard, Washington Court House, Ohio.
757684.	Fan for disinfecting purposes. Wm. W. Rossiter, New York.
757797.	Spirometer. Arthur E. Wells, New York.
757854.	Eye-shade. Nathan R. W[illegible] West Bethlehem, Pa.
758205.	Massage machine. John [illegible]
758440.	Adjustable truss. Maurice [illegible] Pa.
758092.	Ophthalmoscope. Charles McCormick, Chicago.
758597.	Vaccine point. Harry K. Mulford, Philadelphia.
758949.	Device for storing and administering serums. Wm. S Apple and H. K. Mundorf, Philadelphia.
759152.	Inhaler. George L. Bennett, Chicago.
759084.	Surgical operating cushion. Anton C. Eggers, New York. and E. Stahl, Naugatuck, Conn.
759169.	*Artificial hand. Eli T. Forrester,* Deadwood, S. D.
758653.	Massage instrument. John A. Howell, Washington, D. C.
758673.	Vaginal syringe. Christian W. Meinecke, Jersey City, N. J.
759029.	Aseptic drinking cup. John J. Shea, Beverly, Mass
758719.	Inhaler and *respirator.* John W. Swindell, Greenville, Texas.
759229.	Apparatus for testing the eyesight. Adolph and A. C. Bechtold, New York.
759342.	Pessary. Frederick H. Brunig, Kansas City, Mo.
759505.	Massaging instrument. Martin Doerr, San Jose, Cal.
759808.	Treatment of casein. Louis A. Dreyfus, New Brighton, N. Y.
759369.	Apparatus for administering anesthetics. Augustus G. V. Harcourt, Ryde, Isle of Wight, *England.*
759612.	Infant incubator. George H. How, Chicago.
759714.	Spatula and cork extractor. Edwin B. Jelks, Quitman, Ga.
759724.	Dispensing cabinet. Jesse Lines, Sabetha, Kan.
759753.	Artificial foot. James F. Rowley, Chicago.
759397.	Medicament vaporizer. Moritz Saenger, Magdeburg, Germany.
759761.	Thermometer case. Hermann A. Sievert, Fort Walla Walla, Wash.

CHORIO-EPITHELIOMA MALIGNUM VAGINALE POSTPARTUM MATURUM.

ITS ETIOLOGY AND ITS RELATION TO EMBRYONAL TUMORS.*

GEORG SCHMAUCH, M.D.
CHICAGO.

During the last ten years much work has been done in the etiology of malignant growths. While the representatives of pathology still cling to the cellular etiology of tumors, as it became established through the investigations of Virchow, Rokitansky and Cohnheim, clinicians have, on several occasions, proclaimed a germ as the cause of carcinoma or sarcoma. Up to the present time all these discoveries can not withstand criticism. It might appear convenient to find for every sickness and for every malignant growth a special germ, which we might destroy through the immunizing qualities of the animal body, and especially of the blood tissues. But we are still far from a solution of this problem, at least as long as the biology and physiology of the cell are covered with such a dark veil. All the growths, as we know, benign or malignant, follow a certain type, but in recent times we have become acquainted with quite a heterogeneous, specially deleterious growth, which stands beyond the general scheme and which we have to place in a class by itself, as its matrix is formed by fetal tissues which, we may say fortunately, only in a very few cases bring death to the maternal organism. The idea that smallest particles of fetal tissues after normal delivery and puerperium might become dangerous to the mother, and in this way place human maternal life in the same category with that of some insects, whose vital problems and energy end with the act of delivery—this idea could not but be strange to the pathologist and clinician. This tumor Kossmann has shown not to be a modern product, as its descriptions can be traced back to the oldest medical observations. Both the peculiar etiology and the fact that its biology places it among the sarcomas, while its histologic structure agrees with that of carcinoma, have caused numerous detailed publications of such cases. By these we have learned that this tumor, which is more malignant than any other growth, is in very close relation to the myxoma chorii also, and this is the most important result of the modern investigation, that chorio-epithelioma may follow an apparently normal case of labor. Distinct from the latter cases are those in which the uterus has been found perfectly free from tumor.

HISTORY OF THE CASE.

I had the occasion to observe such a case in Berlin, in the Royal Women's Hospital, and as the clinical history of the case is a typical one, I will relate it here:

Patient.—Nov. 25, 1902, an extremely pale patient was brought to me for admittance. She gave the following history.

History.—Mrs. Frieda Z., 23 years old, no previous disease, married six years, four normal spontaneous labors, all children alive. The last delivery, Aug. 20, 1901, was followed by severe postpartum hemorrhage. A physician of our hospital was summoned, but did not think it necessary to do anything; he found the placenta normal and complete. The puerperium was free from trouble. After 14 days, the patient got up and resumed her housework. Three weeks after delivery, during the night, a sudden profuse hemorrhage occurred. Another physician who was called found a retroflected uterus, took this displacement to be the cause of the bleeding, and thought it would stop after correction of the malposition. Nevertheless the hemorrhage kept up four weeks postpartum, its source was discovered in a defect of the vaginal wall (ruptured varix?) and ligature and suture of the bleeding wound performed. Three days later a new hemorrhage took place. A third physician removed a nodule from the vaginal wall. Then the hemorrhage stopped for three weeks. The patient felt very weak during this time, but otherwise perfectly well. She got up, but soon another hemorrhage occurred, which necessitated a new operation. Eight days later a fourth operation had to be done as the nodule, the hematoma, was rapidly growing again. This time a goodly portion of the surrounding tissue was extirpated and the bed of the tumor cauterized with the Paquelin. Aside from this a curettage of the uterine cavity was done. After each operation the hemorrhage stopped for a certain time, only to start again suddenly, and as the patient thought, always in consequence of vomiting. November 7, another operation was performed by a specialist, whereon the bleeding stopped until November 24. At this time a new hemorrhage took place, associated with collapse and fainting. The family physician tamponed the vagina and sent the patient to our hospital.

This history of four or five operations caused by hemorrhage from a vaginal tumor could but force on us the suspicion of a chorio-epithelioma even before further examination.

Examination.—Out of the status præsens I will only mention that the woman was large, well nourished and extremely pale; her pulse was rather small, 110. Examination of her lungs did not reveal anything special. Over the base of the heart a systolic murmur was to be heard. After taking out the deeply blood-stained tampon on the right side of the vagina, close to the entrance at a distance of about one centimeter and a half, a wound was noticed, the size of a 25-cent piece, which had a peculiar appearance. The mucosa of the vaginal wall had a bluish color, was puffy, between the margins of the defect brown masses arose, which very much resembled coagulated blood. On the top of the growth a silk suture was found. A constant stream of arterial blood came out of the wound. The portio was a little to the left of the median line, the uterus retroflected. An attempt to replace this organ, as well as further palpation of the adnexa, seemed to me contraindicated. The urine was muddy, of alkaline reaction. The patient com-tissues by little blood *only*, whereas it is separated by larger blood-masses from the rest of the tumor-tissue, the epithelial masses. This is understood as a sign of the great coherence of the syncytial protoplasm. Nowhere, as in other malignant growths, is there an inflammatory wall, a zone of proliferation to be seen. The progress of the *chorio-epithelioma is not by arrosion*; the delicate and soft structure of the syncytium destroys the neighboring tissues only by their own collapse. From the microscopic sections which are at our command, we have to draw the conclusion that the initial stages of the chorio-epithelioma are to be seen in the cells lying separate in the tissues and cruor-masses, the so-called wander-cells. Under favorable conditions of nutrition, these are multiplied by mitosis; some of them become giant-cells. In these, as well as in the mononuclear tumor-cells, develop vacuoles, which give rise to great distension of the cell. In these vacuoles also appear cells that resemble Langhans-cells. The origin of these cells becomes, in our opinion, evident from the picture of the metastasis of the brain. There we see in the upper half wide cavities partially filled with well-preserved blood corpuscles, and at the points where the meshes interlace we see tumor-cells of the appearance of the Langhans-cells, which are sometimes surrounded again by syncytium. So we are forced to the conclusion *that these cells do not break* in from the outside, but must be derived from the nuclei of the syncytial cells. A tumor-mass having been built up in this way, the farther extension of the growth, not taking into account the propagation by mitotic increase of the epithelium, is mostly a peripheral one. The much-stretched syncytium of the periphery, which by its position immediately in connection with the blood current is under most favorable nutrition, becomes thus condensed in one place and puts forth buds.

---

* Read before the Chicago Gynecological Society.

In these appear nuclei and later on vacuoles, etc. I failed to observe mitosis in the syncytium. In the syncytial buds seem to rise nuclei out of the protoplasma. In this way the growing of these tumors resembles, in my opinion, very much the process of regeneration of muscles and development of blood vessels. Nuclei appear in the buds of the syncytium in a similar way as in buds of muscles and vessels. There, as well as here, we see excrescences, buds, of the protoplasm, and arising in these nuclei and vacuoles. In the buds of blood vessels, as well as in syncytial buds, the protoplasm becomes vacuolated and the blood current breaks in.

NATURE OF THE SYNCYTIUM.

Therefore, I think the syncytium is no specific cell-species, but only a stage in the cell-life of the Langhans epithelium, of the trophoblast. Such metamorphosis of the cell-form, brought on by the surroundings, by the different conditions of life, is not such a very rare occurrence in physiology. The cylindric epithelium of the epidermis becomes horny; the cell of the marrow of the bones first without granulations becomes filled with eosinophile and neutrophile granules. To the pathologist the change of tissues that are closely related, for example, myxomatous in fat-tissue, connective into bone-tissue, as in some cases of arteriosclerosis, is long and generally known, as well as the metaplasia of epithelium in the endometrium and in the mucosa of the urinary passages.

Now, if we take syncytium and Langhans layer to be different stages of the same cells of the trophoblast, then the question of the origin of the syncytium is thereby answered in the sense of fetal descent. This question has kept the observers busy for a long time, and they have tried to come to an agreement by the examination of very early ova of men and animal. Siegenbeck-Heukelom's and Peters' researches resulted in that the majority of authors now have decided in favor of the fetal origin of the syncytium.

That endothelium as well as epithelium may undergo during pregnancy syncytial changes is amply shown by Schmorl, Pels-Leusden, *Marchand and others*. Even in 1897 I was able to demonstrate such syncytial endothelium in the biologic society at Koenigsberg, and concluded that they were due to gestation. The temptation, therefore, was quite strong to assume analogous changes of the epithelium of the uterine glands under the influence of pregnancy, which at that time are forming the lining of the villi. It took fourteen years of diligent research to find out the real nature of the syncytium and the chorio-epithelioma malignum. Most authors were inclined to place this tumor in the well-known ranks of carcinoma or sarcoma. A great diversity of opinion existed; the different names applied to this growth, as deciduoma malignum, deciduosarcoma, syncytiosarcoma, syncytioma, chorio-epithelioma malignum, demonstrate this. *Additional and final information* developed during the last year from the investigations of Schlagenhaufer and Wlassow. By their findings the idea of an endothelial genesis of the syncytium became untenable. Schlagenhaufer noticed chorio-epithelial growths in a teratoma of the testicle and its metastases in a man 43 years of age. The picture he gives of metastases in the lungs resembles perfectly that which you see here; there also in the epithelial nests some cells grow richer in protoplasm and larger, hence are in a stage of transition to syncytium. Schlagenhaufer, by looking through the literature, found four other cases with the same findings. Three of them were tumors of the testicle, the other occurred in a 13-year-old girl who had never menstruated.

The second case concerned a locksmith, 40 years old, who was dissected several years previous by Breuss. The tumor of the testicle had perforated the blood vessels and had produced in the heart formations which were macroscopically perfectly like the vesicles of hydatid mole. This strange discovery—a mole in the heart of a locksmith—certainly removed all doubts as to the possibility of the maternal organism being in any way *connected with the development of the epithelial lining* of the villi. The villi in the Breuss case consist of a soft myxomatous tissue. The epithelial layer is in some places syncytial; in others there are vacuoles or large cells in a state of proliferation. Though their appearance resembles very much the vesicles of hydatid mole, this interpretation is lately questioned by Risel, on account of lack of uniformity in the structure and the appearance of cavities in them that are lined with epithelium. Schlagenhaufer himself concedes that these hydatid formations have been brought on by the breaking in of ektodermal elements into the blood vessels, and that we have to regard them as resulting from the physiologic conditions. But otherwise one has to agree with Pick, who strongly repudiates Risel for doubting his observations. At the operation of a tubal abortion a dermoid cyst of the same ovary was removed. In a separate cavity of this common cystic teratoma, Pick happened to find a growth of the nature of hydatid mole, about the size of an apple. Pick is, in my opinion, perfectly right, if he says that this is not a chorio-epithelial growth, such as is found in the teratomas of the testicle, but the cyst and the mole have to be considered part of the dermoid formation itself.

The last doubt as to the pre-existence and embryonal origin of such chorio-epithelial formations was destroyed by another observation made by Pick only a few weeks ago. He succeeded in finding typical chorio-epithelial tissue in a teratoma of the ovary of a girl 9 years old, a tumor removed eight years ago.

This is another important argument that embryonal germs may produce fetal membranes, a point which we will have to discuss later on; hereby the question whether pregnancy is necessary to develop such formations is settled finally.

Chorio-epithelial growths in teratomas of the testicle are not so very rare, as shown by Wlassow, who was able to find these tissues three times among twelve cases of these tumors. Similar statements were made by Schmorl, Steinhaus, Emanuel, Bostroem, Hansemann. In Bostroem's case it was a retroperitoneal tumor in a man, which had made many metastases in the brain. These proliferations of cells of ektodermal origin in teratomas of the testicle and their metastases, that have to be identified with those in chorio-epithelioma malignum, have proved that pregnancy is not necessary to build up syncytial masses, and that neither the maternal epithelium nor the endothelium has anything to do with them; also that no symbiosis of maternal and fetal cells takes place, but fetal cells alone may form a tumor of the appearance of the chorio-epithelioma malignum.

Marchand pronounced in his second paper the oneness of the syncytium and the Langhans cell-layer, and thinks it very likely that the syncytium is able to proliferate; as well as Virchow and after him Kossmann have expressed the opinion that the syncytium is composed of single cells. Signs of an indirect division of the nuclei we were, like many other authors, unable to detect. On the other hand, our pictures demonstrate that a direct division, a process of budding and splitting takes place. Furthermore, we think we may conclude from our pictures that the proliferation of the syncytium does not always lead to a formation of giant-cells, but that inside of the syncytial masses cells may be formed of the shape of the Langhans cells. Pels-Leusden arrived at the same conclusions in his researches on the serotinal giant-cells. He describes fully in this work the process of fragmentation in protoplasm and nucleus. Pels-Leusden says the syncytial cells are producing daughter-cells, which partly grow into the large giant-cells, in other places again undergo a change in small, epitheloid cells, with one to three light-colored nuclei and a brighter protoplasm. Hence the same process as we find in the metastases in the brain at the knots of the meshes. Pels-Leusden thinks these cells have to be brought into connection with the regeneration of the glandular epithelium, which opinion will be hardly shared by anybody. As stated before, we only can regard the syncytium, like other authors, as a certain stage in cell life, but in contrast to the general opinion, we consider this stage not a phenomenon of degeneration, not a sign of an ended function of the cell: we rather want to have it considered a symptom of the maximum vitality of the trophoblast. Therefore, the name of syncytioma seems to be quite well applied to these tumors; however, I choose in this paper the name of chorio-epithelioma, as this is used most frequently by the modern writers.

Now the most interesting event in the history of the chorio-epithelioma malignum was when the same cellular proliferations in teratoma of the testicle, which, as I have shown, cleared up the mystery of these tumors and the syncytium in German science, an opposition arose in England in the year 1897. At this time a commission was appointed to investigate the question of the deciduoma malignum. Kanthack's case of a very rapidly spreading teratoma of the testicle, whose metastases showed cells of chorio-epithelial character, was taken at this time by Eden, who headed this commission, as a counter-argument against the German doctrines; the commission reported that the deciduoma malignum was no specific tumor.

THE TIME OF ORIGIN OF THE CHORIO-EPITHELIOMA.

Another important question in the pathogenesis of these tumors is the time when they rise. In answering that, only those cases can be taken into consideration in which the uterus has been perfectly free from tumor. They are enumerated in Peter's paper. But even among those the cases of tumors after abortion and hydatid mole do not permit reliable conclusions, because the term of the expulsion of the fetus is not coincident with its death. Six such cases are reported, Schmorl, Lindfors, Huebl, Wehl 2 cases, Schmauch; after normal labor, all the patients died. Reports of the autopsy exist only in the cases of Schmorl, Lindfors and Schmauch. The other cases, in which the endometrium has been sound, where the tumor was situated in the muscle, will not be discussed here. The cases of metastases and infarct of the lungs, which are reported as healed, are of little value also, as in none of them tumor masses became expectorated. The average time, when the neoplasm became manifest, is, according to McKenna, six to ten weeks. In the cases just mentioned of chorio-epithelioma vaginale postpartum maturum, the time elapsing between labor and appearance of the tumor is about the same, three to ten weeks. The vaginal metastasis developed also comparatively early in these cases and all of them without exception have resulted fatally in from ten weeks to one year. It is very improbable that there existed a tumor and metastasis during the pregnancy, as the labor was normal, occurred in term and the child was living, except Huebl's case, where a child was delivered which had been dead a few days. This case is especially interesting, as it was preceded by a hydatid mole one year and a half before the birth that gave rise to the tumor. All cases showed the metastases over the whole body. Concerning the size of the individual metastasis, the biggest tumor was to be found in the lungs and the cerebrum. It is not remarkable that the lung should be involved, but the fact that the brain became involved in so short a time and in such large tumors, conveys to us the idea that the extensive dissemination must have occurred at the same time. The tumor in the vagina, as Schmorl assumes, only seems to be primary. There is no primary tumor in our case, but there has taken place and probably sub partu a general dissemination of tumor infection. However, this is not always necessary, as those cases show where the neoplasm was limited to the uterus and its adnexa, and which were cured with lasting success by operation, of course, only after abortion.

Could dissemination of tumor cells have taken place toward the end of pregnancy? The fatal end of all the cases of chorio-epithelioma after labor in term speaks in favor of this idea. If we assume that the vaginal metastasis is synchronous with the others, then this view becomes very improbable, as otherwise without any doubt a tear of the vagina would have occurred during labor. The growth of these tumors is an extremely rapid one, as can be judged by several unobjectionable observations, where within 14 days a recurrence of the size of a walnut developed. It is the vaginal chorio-epithelioma that forces upon us the idea that the propagation takes place during labor. Peters, too, states that a retrograde embolism of the vaginal veins can only have occurred during labor. While in earlier days we only believed in propagation of syncytial cells in eclampsia, nowadays it is shown by Schmorl, Pels-Leusden, Veit and others that such a "deportation," as Veit names it, is the normal way, even if not always to such a high degree. In my opinion it has to be regarded as a physiologic process. The syncytium is inclined to form buds and prominences, and often they are only connected with the syncytial layer by a small pedicle. Surrounded by the maternal blood, they might easily be torn off and dragged along. This without doubt will be facilitated by the violent shaking in eclamptic convulsions. That a deportation takes place during abortion, too, is shown by the cases following abortion. That it happens very often after hydatid mole, in which case the lining of the villi undergoes an abnormal proliferation, is demonstrated by the fact that chorio-epithelioma follows very frequently this pathologic condition.

Anatomic researches regarding embolism of parenchyma cells, made by Poten in 7 cases of pregnancy, corroborated our opinion of the physiologic possibility of deportation of parts of villi. Poten succeeded in finding torn off villi in the lumen of blood vessels of the uterine muscle in earlier and later months of pregnancy. As in some of his cases labor had not yet started, we only can join the conclusions of this author, that the deportation of villi might occur in every case of pregnancy and at any time. But it is still an open question if this dissemination is limited to the uterus or if the whole system of the woman becomes infected with these cells during pregnancy.

THE ONKOLOGIC PLACE OF THE CHORIO-EPITHELIOMA.

In onkology a special position has to be given to these tumors, as to the teratomas. Even though the structures, which build up these tumors, are epithelial, they are not carcinomas; also though they propagate by means of the blood vessels, common to sarcomas, they must not be numbered among them; it is fetal tissue, a tissue foreign to the maternal organism, which gives rise to these tumors, resembling the embryomata and yet different in that only the ektoderm participates.

Another question is, if mesodermal parts are necessary for the development of a chorio-epithelioma malignum. The discovery of villous parts was one of the first arguments for the fetal origin and many authors went so far as to demand the presence of villi in each case. To-day we are inclined toward the opinion that the deportation of villous substance has nothing to do with the development of the tumor. There has never been detected the least proliferation on the villous tissue itself, and very frequently phenomena of degeneration were found in it. In the metastasis of a carcinoma, the propagation of epithelium is quite sufficient to build up a tumor, in the same way as an implanted cell complex may give rise to so-called "implantation metastasis." In the carcinoma and sarcoma we assume a special malignity of the individual cell; this special epithelial cell emancipates itself from the others. It takes on a new vital power and starts through the lessened resistance of the affected individual a harmful proliferation, without purpose. How is it now with the epithelial lining of the villi? Have we to attribute to the latter, as a fetal product, as a rest of the trophoblast, a special capacity of proliferation? Why does this tissue, the physiologic deportation accepted, grow in one case exuberantly, without bounds? Why does it in other cases only give rise to a local tumor, and why finally, does it remain in most cases without any effect? In consequence of our entire views about embryomata and embryonal tumors we are accustomed to attribute to the stray embryonal cells, to the strayed germs, a strong energy of growth. To make these points more easily understood I shall have to return with a few words to the origin of the embryonal tumors.

OUR MODERN VIEWS ABOUT EMBRYONAL TUMORS.

Embryonal tumors are the only ones whose etiology is at least partially known. We know nowadays through the researches of Marchand, Bonnet, Wilms and others, that the parasitic monsters are congenital tumors and have to be traced back to the earliest stages of development. From these tumors, commonly called teratomas, we previously have separated the embyromata (as Wilms calls them) and the dermoid cysts of the ovaries. But the teratoid growths of the ovaries and the testicle contain, as Wilms, Hanau and others have shown, derivatives of all the three germinal layers. Hence the dermoids of the ovaries, which sometimes comprise very remarkable structures, as finger with fully developed nails, whole extremities, etc., as well as the teratomas of the testicle have to be ranked in their etiology as equal to the fetal inclusions. However, we have to differentiate from these tumors the real dermoid cysts, which arise through an ingrowth and detachment of the cutis and ektoderm. By this process organs and tissues, which are lying close by, might be drawn along, and thus the growth might become quite a complicated structure by the appearance of bone and cartilage and other substance.

These are the tumors which Wilms calls bidermones, in contrast to the first group, which he names tridermones. Etiologically there is a great difference between these two groups, as stated very strikingly by Wilms, in so far, as the dermoid cyst arises at the time of the existence of the germinal layers, whereas the teratomas are products of the epoch of the furrowing of the egg. The old opinion of a parthenogenesis, which means that in the ovulum a kind of self-fecundation takes place, by means of the polar globules, which were to be regarded as male cells after Minot, is nowadays abandoned by most authors. There does not exist a parthenogenesis in mammalia, only the ripe ovum and that only after fecundation is capable of development. Marchand-Bonnet's idea of a uniformity of fetal inclusions and teratomas of the sexual glands has taken the place of parthenogenesis and is now generally accepted. The congenital foundation of these tumors and the possibility of their development at any age has to be recognized nowadays. This much is known, while it is still a point of controversy whether a fecundated polar globule, as Marchand suggests, or a strayed and afterwards included blastodermic cell, as Wilms thinks, is the original source of these teratomas. Marchand already lays down the necessity of proving fetal membranes in these tumors, to support his opinion, and Bonnet also demands their existence, as the only means of differentiation of the real embryoma from the dermoid cyst. It seemed first as if this demand was fulfilled by the discovery of chorio-epithelial proliferations and hydatid formations in teratomas of the testicle and by Pick's cases of dermoid cysts. However, these facts did not bring about any further advance in our knowledge, because there is no reason why a misplaced blastomere should not possess the faculty to build up fetal membranes and their derivatives. We do not as yet know why in some of the teratomas of the testicle such immense chorio-epithelial masses are formed, why in these cases the proliferation of the ektoderma takes such an appearance. On the other hand this phenomenon of an absolute preponderance of one tissue is not without parallel in pathology, as, for instance, the dermoid of Saxer, where there was but one tooth imbedded in the ovarian substance, and the cases of so-called *struma ovarii.*

THE TERATOID HYPOTHESIS OF THE CHORIO-EPITHELIOMA.

Schlagenhaufer is perfectly right in explaining the chorio-epithelial proliferations in teratomas of the testicle by the Marchand-Bonnet theory, in referring these teratomas to stray blastomeres, but he goes still farther and asserts that the chorio-epithelioma malignum of the woman is nothing more than a teratoid growth. He says in the first week of pregnancy a germ of the fecundated ovum, which otherwise is used to develop fetal membranes, gets misplaced and gives rise after expiration of this or a later pregnancy to the chorio-epithelioma, while the abortive ovum (in which only fecundated polar globule is developed, while the rest perishes), will produce a hydatid mole.

According to Schlagenhaufer, the chorio-epithelioma of the woman in its genesis is equal to the fetal inclusions and teratomas. However, this opinion must be strongly objected to. A principal difference is to be seen in the fact that the latter tumors proceed from the same ovum and autochthonously develop growths, in the same individual, at a later period of life; whereas the chorio-epithelioma is in a certain way a heterochthonous teratoma, that is, the germ that produces this tumor belongs to a second individual, though this second individual be the product of the bearer of the tumor. Suppose we accept the idea of abortive, included polar globules, suppose we could conceive that germs which remained behind in the development, get misplaced at the time of the segmentation and the formation of the germinal layers and become imbedded in the layer of any other organ, as for example that of the sexual organ; still we have no right to assume such a degree of misplacement, that in a second the maternal organism should arise a teratoid tumor, a chorio-epithelioma, be it in the parametrium or in a still more distant organ. Schlagenhaufer's theory always assumes a primary tumor. Accepting his idea of far-spread germs of the fecundated ovum, theoretically we should have to expect teratomas to occur as a consequence of pregnancy, something so far entirely unknown. In all cases of teratomas with chorio-epithelial proliferations the latter only make up a part of the tumor, that part which chiefly produces metastases. The tumor itself, as well as some of the metastases generally present elements of the two other germinal layers. However, in none of the many cases of chorio-epithelioma malignum have so far parts of the meso, and hypoblast been discovered. If Schlagenhaufer says that a mature villus is no longer able to develop sufficient energy of growth to result in a chorio-epithelioma malignum, we shall have to reply that in the cases of Pick, Poten-Vasmer, Gebhard and others, a direct connection between the tumor and the deported villus is to be seen.

THE DIFFERENT THEORIES ABOUT CHORIO-EPITHELIOMA.

By our anatomical researches we are forced to accept a physiological deportation of the lining of the villi, and, as we think, there are only two possibilities by which to explain the histogenesis of our tumors. One of them is, to attribute to the epithelium of the villi a special pathologic energy of proliferation in all cases in which chorio-epithelioma arose after pregnancy. The second one is as follows: The trophoblast and its developmental stages, Langhan's epithelium and syncytium, preserves the faculty of proliferating, which is the property of all embryonal tissues, during the whole time of pregnancy, but is displayed only in case of certain changes of the maternal organism. Hitschmann and Lindenthal, through their findings on a young ovum, and Franz by his examination in a case of ovarian pregnancy, made it evident that not the villi themselves penetrate the serotina, as we thought, but that the lining with trophoblast enables them to assume this function. Just as the syncytial cells of the chorio-epithelioma malignum are progressing in the tissues of the different organs, in the same way the cells of the trophoblast are pushing forward in the mucosa of the uterus and in the spongiosa. In the very early days of pregnancy the villi are not covered by syncytium and Langhan's cells, but only by the masses of the trophoblast. Both authors point to the identity of the chorio-epithelioma malignum and the development of the ovum in utero and render it clear, that this advance of fetal cells in the maternal tissues is without comparison in the whole field of physiology and finds an analogy only in the advance of tumor cells. The question is now, do we have to attribute this quality to the trophoblast, which is differentiated into syncytium and cell layer or even totally converted into syncytium?

Anatomic examinations of the epithelial lining of the villi of the placenta, women, which afterwards became ill with chorio-epithelioma, unfortunately do not exist. The idea that there might have been a malignant tumor of the placenta has been sufficiently disproven. Great changes could not have taken place, as mentioned above, as otherwise the birth of a living mature child becomes improbable. The placenta in our case, in which we had an atonic hemorrhage from the uterus had been inspected by a skilled physician, who could not detect any macroscopic changes.
